Platinum, sulphides of. Pt and S combine when heated together. Two sulphides have been isolated,  $\text{PtS}$  and  $\text{PtS}_2$ ; there is also evidence of the existence of  $\text{Pt}_2\text{S}_3$ .

PLATINUM MONOSULPHIDE  $\text{PtS}$  (*Platinous sulphide*). Obtained by heating Pt black and S, and volatilising excess of S, in absence of air; also by heating  $(\text{NH}_4)_2\text{PtCl}_6$  with S, out of contact with air, till  $\text{NH}_4\text{Cl}$  and excess of S are volatilised; also by passing  $\text{H}_2\text{S}$  into  $\text{PtCl}_4\text{aq}$  (Berzelius). Prepared in crystals by heating to redness a mixture of 1 pt. Pt, 1 pt. borax, and 10 pts. pyrites (Deville & Debray, *A. Ch.* [2] 55, 215). A grey, lustrous solid; S.G. 6.2.  $\text{PtS}$  prepared in the wet way is a black powder. Unchanged in air, even when moist; unacted on by boiling acids; loses S when heated in air, leaving Pt; reduction in H begins at  $19^\circ$ . A compound with CO— $\text{PtS}\cdot \text{CO}$ —was obtained by Mylius & Förster (*B.* 24, 2438) by the action of  $\text{H}_2\text{S}$  on  $\text{PtCl}_4\cdot \text{CO}$ .

PLATINUM DISULPHIDE  $\text{PtS}_2$  (*Platinic sulphide*). Obtained by passing  $\text{H}_2\text{S}$  into  $\text{Na}_2\text{PtCl}_6\text{aq}$ , or by dropping  $\text{H}_2\text{PtCl}_6\text{aq}$  into solution of an alkali hydrosulphide. Also formed

by digesting, in a strong closed flask, 1 pt.  $\text{PtCl}_2$ , 4 pts. alcohol, and 5 pts.  $\text{CS}_2$  (Böttger, *J. pr.* 3, 274); and by decolorising  $\text{H}_2\text{PtCl}_6\text{Aq}$  by  $\text{SO}_2$ , and then heating in a sealed tube at  $200^\circ$  (Geitner, *A.* 129, 358).  $\text{PtS}_2$  is also a product of the action of  $\text{HClAq}$  in air on  $\text{Na}_2\text{Pt}_2\text{S}_6$  or  $\text{H}_2\text{Pt}_2\text{S}_6$  (v. THIOPLATINATES, p. 281). Colloidal soluble  $\text{PtS}_2$  was obtained by Winssinger (*Bl.* [2] 49, 452) by passing  $\text{H}_2\text{S}$  into very dilute  $\text{PtCl}_2\text{Aq}$ , and dialysing. A black solid; as obtained from  $\text{Na}_2\text{Pt}_2\text{S}_6$  forms steel-grey needles, S.G. 5.27.  $\text{PtS}_2$  prepared by one of the wet methods must be dried in absence of air, else it is partially decomposed. Heated out of air forms  $\text{PtS}$ , and Pt and S. Oxidised to sulphate by strong oxidisers, such as *aqua regia*, Cl, fuming  $\text{HNO}_3$ , molten  $\text{KClO}_3$  or  $\text{KNO}_3$ . Freshly ppd.  $\text{PtS}_2$  dissolves in alkali sulphide solutions forming *thioplatimates* (q. v.), from which solutions it is reppd. by acids. Clässon (*J. pr.* [2] 15, 193) describes a compound with  $\text{EtSH}$ .

**PLATINUM SESQUISULPHIDE,  $\text{Pt}_2\text{S}_3$ .** This compound is said to be formed, as a steel-grey, metal-like solid, S.G. 5.52, by the oxidation in air of  $\text{H}_2\text{Pt}_2\text{S}_6$  (Schneider, *P.* 136, 105; 138, 604; 139, 661; 141, 519; 148, 633; 149, 381). Schneider also describes a compound  $4\text{PtS.PtS}_2 = \text{Pt}_5\text{S}_7$ .

**Platinum, sulphocyanides of:** v. vol. ii. p. 857; v. also Guareschi, *Giorn. della R. Accad. di Med.* 1891. No. 5; abstract in *B.* 25, Ref. 7.

**Platinum, thiocarbide of,  $\text{PtCS}_2$ .** This compound is described by Schützenberger (*C. R.* 111, 891). It is a black powder; obtained by passing a stream of N, or H, charged with  $\text{CS}_2$ , over spongy Pt heated to  $400^\circ\text{--}450^\circ$ .

M. M. P. M.

**PLATINUM-AMMONIUM COMPOUNDS** (*Ammonio-platinum compounds. Ammoniacal platinum bases. Platinammines*). When a solution of  $\text{PtCl}_2$  in  $\text{HClAq}$  reacts with  $\text{NH}_3$ , more than one compound of the form  $\text{PtCl}_2 \cdot 2\text{NH}_3$  is obtained. These compounds react with acids, oxidisers, &c., to form many derivatives containing Pt, N, H, and negative radicles, in which the reactions of Pt and  $\text{NH}_3$  are more or less modified.

The platin-ammonium compounds may be regarded as salts of bases derived from two or more  $\text{NH}_3$  groups, in which part of the H is replaced by Pt; thus  $\text{PtCl}_2 \cdot 2\text{NH}_3$  may be called platoso-diammonium chloride, and formulated as  $\text{N}_2\text{H}_5\text{PtCl}_4$ . Similarly  $\text{PtCl}_2 \cdot 4\text{NH}_3$  may be

regarded as  $\text{Pt} \begin{smallmatrix} \text{NH}_3 \cdot (\text{NH}_3)\text{Cl} \\ \text{NH}_3 \cdot (\text{NH}_3)\text{Cl} \end{smallmatrix}$ , and called ammo-

nium platoso-diammonium chloride. The compounds derived from  $\text{PtCl}_2$  are regarded, in this scheme, as platin-ammonium compounds; thus,  $\text{PtCl}_2 \cdot 2\text{NH}_3$  is  $\text{Cl.Pt.NH}_3 \cdot \text{NH}_3 \cdot \text{Cl}_2$  (v. Hofmann, *T.* 1851. [2] 357; Weltzien, *A.* 97, 19; Kolbe, *J. pr.* [2] 2, 217; Grimm, *A.* 99, 67).

This view of the constitution of the compounds in question was opposed by Claus (*J. pr.* 63, 99), Blomstrand (*B.* 4, 40, 639, 673; 6, 1469), Jørgensen (*J. pr.* [2] 33, 489), and others. Jørgensen found that pyridine,  $\text{N.C}_5\text{H}_5$ , forms a compound with platinum chloride similar to  $\text{PtCl}_2 \cdot 4\text{NH}_3$ ; in this pyridine compound, which has the composition  $\text{PtCl}_2 \cdot 4\text{NC}_5\text{H}_5$ , the atoms of hydrogen cannot be in direct union with N; for

the constitution of pyridine is known to be

Now if the ammoniacal platinum

bases are all to be derived from  $\text{NH}_3$ , by substituting H by  $\text{NH}_2$  groups, it is evident that the substituted H atoms must always be directly bound to N atoms. But the existence of the pyridine compound shows that this is not necessary. Hence  $\text{PtCl}_2 \cdot 4\text{NH}_3$  may be regarded as

The classification and nomenclature of the platin-ammonium compounds proposed by Blomstrand (*Chemie der Jetztzeit*, Heidelberg, 1869; *B.* 2, 202; 4, 40, 639, 673; 6, 1469) is now usually adopted. In the following formulæ R stands for a monovalent negative radicle. Blomstrand uses the term *ammine* to distinguish these compounds from the amines, which contain the group  $\text{NH}_2$ .

#### Class I. PLATO- or PLATOSO- COMPOUNDS.

##### Series 1. *Platosamidammines*, $\text{RPtNH}_2\text{R}$ .

" 2. *Platosammines*,  $\text{Pt}(\text{NH}_2\text{R})_2$ .

" 3. *Platodiammines*,  $\text{Pt}(\text{NH}_2\text{NH}_2\text{R})_2$ .

" 4. *Platosamidammines*,  $\text{Pt}(\text{NH}_2\text{NH}_2\text{R})_2$ .

" 5. *Platomonodiammines*,  $\text{Pt}(\text{NH}_2\text{NH}_2\text{R})(\text{NH}_2\text{R})$ .

Series 2 and 4 are isomeric. Cleve has isolated two distinct aniline compounds,  $\text{Pt}(\text{NH}_2)_2 \cdot (\text{C}_6\text{H}_5\text{NH}_2)_2 \cdot \text{R}_2$  (cf. Jørgensen, *J. pr.* [2] 33, 489).

#### Class II. PLATINI- or PLATIN- COMPOUNDS.

##### Series 1. *Platinammines*, $\text{R}_2\text{Pt}(\text{NH}_2\text{R})_2$ .

" 2. *Platinidiammines*,  $\text{R}_2\text{Pt}(\text{NH}_2\text{NH}_2\text{R})_2$ .

" 3. *Platinamidammines*,  $\text{R}_2\text{Pt}(\text{NH}_2\text{NH}_2\text{R})_2$ .

" 4. *Platinmonodiammines*,  $\text{R}_2\text{Pt}(\text{NH}_2\text{NH}_2\text{R})(\text{NH}_2\text{R})$ .

" 5. *Platintriammines*,  $\text{R}_2\text{Pt}(\text{NH}_2\text{NH}_2\text{R})_2$ .

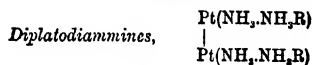

Series 1 and 3 are isomeric.

The prefixes *mono*, *di*, &c., are used to denote the number of  $\text{NH}_2$  groups in direct union with one another, and not the number of  $\text{NH}_2$  groups in union with the atom of Pt. As the compounds in Series 3 contain one diammine chain,  $(\text{NH}_2\text{NH}_2)$ , they are called *semidiammines*; and as those in Series 4 contain a diammine and a monammine chain, they are called *monodiammines*.

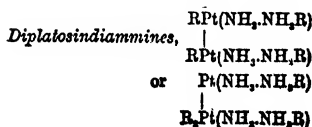

#### Class III. DIPLATINUM COMPOUNDS.

These contain 2 Pt atoms; the group Pt, may be divalent, tetravalent, or hexavalent.

##### Series 1.

##### Series 2.

## Series 3.

## Diplatinammines,

## Series 4.

## Diplatinidiammines,

Iodides of platinum bases with 4 and 8 atoms Pt are also known;  $\text{I}_2\text{Pt}_4\cdot 8\text{NH}_3\cdot \text{I}_2$ , and  $\text{I}_2\text{Pt}_8\cdot 16\text{NH}_3\cdot \text{I}_2$ .

Many organic bases, such as aniline, pyridene, &c., can take the place of  $\text{NH}_3$  in these compounds, and the N of  $\text{NH}_3$  is often replaceable by P or As.

## Class I. Plato- or Platoso- compounds.

Series 1. *Platosemiammines*,  $\text{Pt}(\text{NH}_3)_2\text{R}$ . None of these has been isolated, but Cossa (*B.* 23, 2503) has obtained a compound which probably contains platosemiammine chloride; the compound is  $2\text{Pt}(\text{NH}_3)_2\text{Cl}_2\cdot \text{Pt}(\text{NH}_3)_2\text{Cl}_2$ .

Series 2. *Platosammines*,  $\text{Pt}(\text{NH}_3)_2\text{R}$ . These compounds are generally obtained by heating the corresponding platodiammines,  $\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{R})_2$ , which thus lose  $2\text{NH}_3$ ; by heating with  $\text{NH}_3\text{Aq}$ , platodiammines are re-formed; with oxidisers, platini- compounds are obtained.

PLATOSAMMINE CHLORIDE  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$  (Peyrone, *A.* 51, 1; 55, 205; 61, 178). Obtained by heating  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$  (plato-diammine chloride) to  $250^\circ$ , or by evaporating that compound with  $\text{HClAq}$  at  $100^\circ$  and dissolving out  $\text{AmCl}$  in water; also by evaporating with  $\text{HCl}$  the solution of the corresponding nitrate or sulphate. Microscopic, sulphur-yellow crystals. *S.* 0.22 at  $0^\circ$ , .77 at  $100^\circ$ . Sol.  $\text{NH}_3\text{Aq}$ , forming  $\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{Cl})_2$  (platodiammine chloride); in *aqua regia* forms  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2\text{Cl}_2$  (platianamine chloride). With  $\text{AgNO}_3\text{Aq}$ , in the ratio  $2\text{Pt}(\text{NH}_3)_2\text{Cl}_2:\text{AgNO}_3$ , one half of the chloride remains unchanged and one half gives  $\text{Pt}(\text{NH}_3)_2(\text{NO}_3)_2$ . Heated to  $270^\circ$ , the chloride is decomposed thus:

## Platosemidiammine chloride

$\text{Pt}(\text{NH}_3)(\text{NH}_2\text{Cl})\text{Cl}$ , and *platodiammine chloride platinous chloride*  $\text{Pt}(\text{NH}_3)(\text{NH}_2\text{Cl})_2\cdot \text{PtCl}_2$  (Magnus' green salt), are isomeric or polymeric with platosemiammine chloride. Other compounds, perhaps also isomeric, were obtained by Peyrone (*Lc.*) and by Cossa (*B.* 23, 2503).

Grinnam (*A.* 99, 67) obtained a double compound with  $\text{AmCl}$ ;  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2\cdot 2\text{AmCl}$ . Jørgensen (*J. pr.* [2] 33, 489) obtained the pyridine compound  $\text{Pt}(\text{NC}_5\text{H}_5)_2\text{Cl}_2$ ; and also the mixed compound  $\text{Pt}(\text{NC}_5\text{H}_5)_2\text{Cl}_2\cdot \text{Pt}(\text{NH}_3)_2\text{Cl}_2$  (v. also Hedin, *Dissertation*, Lund; *B.* 20, Ref. 108).

## PLATOSAMMINE HYDROXIDE

$\text{Pt}(\text{NH}_3)_2\text{OH}(\text{NH}_2\text{OH})$ . Said to be obtained, as a crystalline, very soluble solid, by decomposing the sulphate,  $\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{OH})\text{SO}_4$ , by  $\text{BaOAc}$  (Odling, *C. N.* 21, 269, 289). The compound thus formed may have been the isomeric *platosemidiammine hydroxide*,  $\text{OH}(\text{Pt}(\text{NH}_3)_2\text{NH}_2\text{OH})$ . A solution of Odling's hydroxide reacts strongly alkaline, absorbs  $\text{CO}_2$  from the air, neutralises acids, decomposes salts of  $\text{NH}_4$ , giving off  $\text{NH}_3$ , and ppts. many metallic hydroxides from salts of the metals.

PLATOSAMMINE OXIDE  $\text{Pt}(\text{NH}_3)_2\text{O}$ . A

grey solid, insol. water or  $\text{NH}_3\text{Aq}$ ; heated in a retort to  $195^\circ$  gives  $\text{N}$ ,  $\text{NH}_3$ ,  $\text{H}_2\text{O}$  and Pt. Obtained by heating platodiammine hydroxide  $\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{OH})_2$  to  $110^\circ$  (Reiset, *A. Ch.* [3] 11, 417).

PLATOSAMMINE SULPHONATES and CHLOROSULPHONATES  $\text{Pt}(\text{NH}_3)_2\text{SO}_3\text{M}$ ,  $\text{Pt}(\text{NH}_3)_2\text{SO}_3\text{M}$  and  $\text{Pt}(\text{NH}_3)_2\text{Cl}(\text{NH}_2\text{SO}_3\text{M})$ . Ammonium *platosammine sulphate*,  $\text{Pt}(\text{NH}_3)_2(\text{SO}_3\text{Am})_2$ , is formed by the reaction of excess of  $\text{Am}_2\text{SO}_4\text{Aq}$  on  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$  (Peyrone, *A.* 51, 1; 55, 205; 61, 178). The salts of Ba, Co, Cu, Pb, Mn, Ni, Ag, Na,  $\text{UO}_2$ , and Zn have been obtained. Ammonium *platosammine chlorosulphonate*,  $\text{Pt}(\text{NH}_3)_2\text{Cl}(\text{NH}_2\text{SO}_3\text{Am})\cdot \text{H}_2\text{O}$ , is obtained, in colourless rhombic tablets, by leading  $\text{SO}_2$  into a boiling solution of  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$ , and neutralising with  $\text{NH}_3\text{Aq}$ . If the neutralisation is omitted, *platosammine chlorosulphonic acid*,  $\text{Pt}(\text{NH}_3)_2\text{Cl}(\text{NH}_2\text{SO}_3\text{H})$ , is obtained (Peyrone, *Lc.*).

The other salts of the platosammine series which have been isolated are the following;  $\text{M} = \text{Pt}(\text{NH}_3)_2$ :—bromide,  $\text{MBr}$  (Jørgensen, *J. pr.* [2] 33, 521, 531, 535); cyanide,  $\text{MCy}$  (Buckton, *A.* 92, 280); iodide,  $\text{MI}$  (Cleve, *Bl.* [2] 7, 12; 17, 482; Reiset, *A. Ch.* [3] 11, 417); nitrate and nitrite,  $\text{M}(\text{NO}_3)_2$  and  $\text{M}(\text{NO}_2)_2$  (Cleve, *Lc.*); sulphates and sulphite,  $\text{MSO}_4\cdot \text{H}_2\text{O}$  and  $\text{MSO}_3\cdot \text{H}_2\text{O}$  (Cleve, *Lc.*); and *sulphocyanide*,  $\text{M}(\text{CyS})$  (Buckton, *Lc.*). Substituted derivatives of the bromide, of the form  $\text{Pt}(\text{NH}_2\text{RBr})_2$  and  $\text{Pt}(\text{NH}_2\text{RBr})(\text{NH}_2\text{R})$ , where  $\text{R} = \text{Et}$ ,  $\text{Me}$ , or  $\text{Pr}$ , have been obtained (Jørgensen, *Lc.*).

## Series 3.—Platodiammines

$\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{R})_2$ . Formed by action of  $\text{NH}_3\text{Aq}$  on platinumous salts, platosammine or platosemidiammine compounds. Easily lose  $\text{NH}_3$  on heating, giving platosammine compounds. Give platindiammine compounds by action of oxidisers.

## PLATODIAMMINE CHLORIDE

$\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{Cl})_2\cdot \text{H}_2\text{O}$  (Reiset, *A. Ch.* [3] 11, 417). Sometimes called *Reiset's first chloride*. Obtained by the prolonged action of boiling  $\text{NH}_3\text{Aq}$  on  $\text{PtCl}_2$ . Magnus's green salt (v. *infra*), platosammine chloride  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$ , or platosemidiammine chloride  $\text{Pt}(\text{NH}_3)(\text{NH}_2\text{Cl})\text{Cl}$ , precipitation by alcohol, and crystallisation from water. Also formed by reduction of platindiammine chloride  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{Cl})_2$ , by  $\text{H}_2\text{S}$  (Thomson, *J.* 1868, 278). Large, colourless, tetragonal crystals; *S.* 25 at  $16.5^\circ$ , more sol. hot water; insol. absolute alcohol and ether. Addition of  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{HNO}_3\text{Aq}$ , or  $\text{H}_2\text{C}_2\text{O}_4\text{Aq}$  ppts. the corresponding sulphate, nitrate, or oxalate. By gently warming with  $\text{HNO}_3\text{Aq}$  the salt  $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{Cl})_2$  is formed;  $\text{Cl}$ ,  $\text{Br}$ , and  $\text{FeCl}_3\text{Aq}$  react similarly. At  $240^\circ$ – $270^\circ$   $\text{NH}_3$  is given off, and  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$  is formed (v. PLATOSAMMINE CHLORIDE, *supra*). Combines with  $\text{PtCl}_2$ , and  $\text{PtCl}_4$ , to form  $\text{M}(\text{PtCl}_2)_2$  and  $\text{M}(\text{PtCl}_4)_2$ , respectively [ $\text{M} = \text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{Cl})_2$ ]. Compounds are known in which  $\text{NH}_3$  is wholly or partly replaced by pyridine, also by alkyl radicles (Jørgensen, *J. pr.* [2] 83, 489), and also by  $\text{PEt}_3$  (Cahours & Gal, *C. R.* 70, 1881).

Double compounds. Combines with various metallic chlorides to form compounds of the form  $\text{M}(\text{XCl})_2$ , where  $\text{M} = \text{Pt}(\text{NH}_3)_2(\text{NH}_2\text{Cl})_2$ , and  $\text{X} = \text{Pt}$ ,  $\text{Cu}$ ,  $\text{Pb}$ ,  $\text{Hg}$ ,  $\text{Sn}$ , and  $\text{Zn}$  (v. Thomson, *J.* 1868, 278; Buckton, *C. J.* 5, 213; Millon & Commaille, *C. R.* 57, 822).

The most important of these compounds is **PLATODIAMMINE CHLORIDE PLATINOUS CHLORIDE**, known as *Magnus's green salt*,  $\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2\text{PtCl}_2$ . This salt is obtained by the action of  $\text{NH}_3\text{Aq}$  on  $\text{PtCl}_2$  in  $\text{HClAq}$ , or on  $\text{PtCl}_2$  in  $\text{HClAq}$  after passing in  $\text{SO}_2$  till  $\text{AmCl}$  ceases to give a pp. (Magnus, *P.* 14, 242; Gros, *A.* 27, 241). Also by adding  $\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2$  to  $\text{PtCl}_2$  in  $\text{HClAq}$ . It is best prepared by making  $\text{Am}_2\text{PtCl}_6$  from  $\text{PtCl}_2$  in  $\text{HClAq}$  treated with  $\text{SO}_2$ , and crystallised from  $\text{AmClAq}$ , and heating this with  $\text{HClAq}$  and  $\text{NH}_3\text{Aq}$  (Claus, *A.* 107, 138). Green, microscopic prisms or needles; insol. water, alcohol, and dilute  $\text{HClAq}$ . Digestion with hot  $\text{NH}_3\text{Aq}$  forms  $\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2$ ;  $\text{Cl}$ ,  $\text{Br}$ , or  $\text{HNO}_3\text{Aq}$  produces platindiammines (Gros, *l.c.*; Raewsky, *A. Ch.* [3] 22, 278). Boiling with  $\text{AgNO}_3\text{Aq}$  produces  $\text{PtCl}_2$  and  $\text{Pt}(\text{NH}_3\text{NH}_2\text{NO}_2)_2$ . If the empirical formula  $\text{nPt}(\text{NH}_3)_x\text{Cl}_y$  is given to Magnus's green salt, it is seen to be isomeric, or polymeric, with platosamine chloride  $\text{Pt}(\text{NH}_3\text{Cl})_2$ , platosemidiammine chloride  $\text{Cl}_2\text{Pt.NH}_3\text{NH}_2\text{Cl}$ ,

platomonodiammine chloride platinoous chloride  $2\text{Pt}(\text{NH}_3\text{Cl})(\text{NH}_3\text{NH}_2\text{Cl})\text{PtCl}_2$ , diplatosindiammine chloride  $\text{Cl}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2$ , and with a double salt obtained by Cossa (*B.* 23, 2503),  $2\text{Pt}(\text{NH}_3\text{Cl})_2\text{Pt}(\text{NH}_3)_2\text{Cl}_2$ .

**PLATODIAMMINE HYDROXIDE**  $\text{Pt}(\text{NH}_3\text{NH}_2\text{OH})_2$ . Sometimes called *Reiset's first base* (Reiset, *A. Ch.* [3] 11, 417). White, crystalline, deliquescent needles; by decomposing the sulphate by the proper quantity of  $\text{BaOaq}$ , filtering, and evaporating *in vacuo*. Solution in water is strongly alkaline, absorbs  $\text{CO}_2$  from the air, and drives out  $\text{NH}_3$  from  $\text{NH}_4$  salts.  $\text{NH}_3$  is not given off when an aqueous solution is boiled alone or with potash. Melts at  $c. 110^\circ$ ; at a higher temperature gives off  $\text{NH}_3$  and  $\text{H}_2\text{O}$  and leaves platosamine oxide  $\text{Pt}(\text{NH}_3)_2\text{O}$  (*q. v.* p. 293).

The other chief compounds of the platodiammine series are the following;  $\text{M} = \text{Pt}(\text{NH}_3)_2$ ; — carbonates,  $\text{MCO}_3\text{aq}$  and  $\text{M}(\text{CO}_3\text{H})_2$  (Peyrone, *A.* 51, 14; Reiset, *A. Ch.* [3] 11, 417); chromates  $\text{MCrO}_4$  and  $\text{MCr}_2\text{O}_7$ ; bromide,  $\text{MBr}_2\text{aq}$  (Cleve, *J.* 1867, 821); iodide,  $\text{MI}_2\text{aq}$  (Cleve); nitrate and nitrite,  $\text{M}(\text{NO}_3)_2$  and  $\text{M}(\text{NO}_2)_2\text{aq}$  (Peyrone, *l.c.*); phosphate,  $\text{MHPO}_4\text{aq}$  (Cleve, *Bl.* [2] 7, 12; 17, 482); sulphate and sulphites,  $\text{MSO}_4$ ,  $\text{M}(\text{SO}_3\text{H})_2\text{aq}$  (Cleve, *l.c.*).

**Series 4. Platosemidiammines**,  $\text{Pt}(\text{NH}_3\text{NH}_2\text{R})\text{R}$ . Generally formed from the chloride by double decomposition; the chloride is a product of the action of  $\text{NH}_3\text{Aq}$  or  $(\text{NH}_3)_2\text{CO}_3\text{aq}$  on  $\text{PtCl}_2$ . Prolonged treatment of the platosemidiammines with  $\text{NH}_3\text{Aq}$  produces diammine compounds. Jørgensen (*J. pr.* [2] 33, 489) has replaced  $\text{NH}_3$  in these compounds by alkyl radicles and by pyridine.

**PLATOSEMIDIAMMINE CHLORIDE**  $\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2$

Sometimes called *Peyrone's chloride*.  $\text{PtCl}_2$  is formed by the action of  $\text{SO}_2$  on  $\text{PtCl}_2$  in  $\text{HClAq}$ , and the solution is heated to boiling with excess of  $(\text{NH}_3)_2\text{CO}_3$  until the red solution has become light-yellow and a greenish-brown pp. forms, when the liquid is rapidly filtered. The chloride separates as the liquid cools; it must be filtered off at once (else it may re-dissolve), and crystallised from boiling water (Peyrone, *A.* 51, 14; 55,

209; *v. also* Thomsen, *Gm.-K.* 8, 1115; Cleve, *Bl.* [2] 7, 12, 17, 482). Small yellow crystals.  $S. 26$  at  $0^\circ$ ,  $3.6$  at  $100^\circ$ . Decomposes at  $270^\circ$ , giving off  $\text{NH}_3$  and  $\text{HCl}$ . Boiling  $\text{NH}_3\text{Aq}$  forms platodiammine chloride,  $\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2$ ;  $\text{Cl}$ ,  $\text{Br}$ ,  $\text{I}$ , and some other oxidisers produce platisemidiammine compounds,  $\text{R}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{R})\text{R}$ . With  $\text{AgNO}_3$  and  $\text{Ag}_2\text{SO}_4$ , the corresponding nitrate and sulphate are formed.

It is doubtful whether the *hydroxide*  $\text{Pt}(\text{NH}_3\text{NH}_2\text{OH})\text{OH}$  has been prepared; the compound obtained by Odling (*C. N.* 21, 269, 289) was this or the isomeric platosamine hydroxide,  $\text{Pt}(\text{NH}_3\text{OH})_2$  (*v. PLATOSAMMINE HYDROXIDE*, p. 293). The other compounds of this series which have been obtained are the following;  $\text{M} = \text{Pt.NH}_3\text{NH}_2$ ; — bromide,  $\text{MBr}_2$ ; chloro-sulphonic acid,  $\text{MCl.SO}_3\text{H}$  (Cleve, *l.c.*); iodide,  $\text{MI}_2$ ; nitrate and nitrite,  $\text{M}(\text{NO}_3)_2$  and  $\text{M}(\text{NO}_2)_2$ ; sulphate,  $\text{MSO}_4$ ; double sulphites,  $\text{MSO}_3.2\text{X.SO}_3$ ,  $\text{X}_2 = 2\text{NH}_3$ ,  $\text{Ba}$ ,  $\text{Co}$ ,  $\text{Ag}$ ; these may be regarded as compounds of sulphites with salts of the hypothetical *platosemidiammine sulphonic acid*  $\text{Pt}(\text{NH}_3\text{NH}_2\text{SO}_3\text{H})\text{SO}_3\text{H}$ .

#### Series 5. Platomonodiammines

$\text{Pt}(\text{NH}_3\text{NH}_2\text{R})(\text{NH}_3\text{R})$ . Most of the salts of this series are prepared from the double salt of the chloride with  $\text{PtCl}_2$ .

**PLATOMONODIAMMINE CHLORIDE PLATINOUS CHLORIDE**  $2\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2\text{PtCl}_2$ . This compound is one product of the action of  $\text{NH}_3\text{Aq}$  on  $\text{PtCl}_2$  in  $\text{HClAq}$ ; it is prepared by neutralising  $\text{PtCl}_2$  in  $\text{HClAq}$  by  $(\text{NH}_3)_2\text{CO}_3\text{aq}$ , heating to boiling, and adding  $(\text{NH}_3)_2\text{CO}_3\text{aq}$  drop by drop, when it separates in small red tablets (Peyrone, *A.* 55, 209). Fairly sol. cold water, more sol. hot water. Boiled with  $\text{NH}_3\text{Aq}$  forms Magnus's green salt,  $\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2\text{PtCl}_2$ . Isomeric, or polymeric, with Magnus's green salt, platosamine chloride, and platosemidiammine chloride.

#### PLATOMONODIAMMINE CHLORIDE

$\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})_2$ . Obtained in lustrous colourless crystals, by adding  $\text{HClAq}$  to an ice-cold solution of the nitrate.

#### PLATOMONODIAMMINE NITRATE

$\text{Pt}(\text{NH}_3\text{NH}_2\text{NO}_3)_2$ . Formed by decomposing the chloride in solution by  $\text{AgNO}_3\text{aq}$ , filtering, and evaporating. The *sulphate*

$\text{Pt}(\text{NH}_3\text{NH}_2)_2\text{SO}_4\text{H}_2\text{O}$  is also known (*v. Cleve, l.c.*; Blomstrand, *B.* 4, 40, 639, 673; 6, 1469).

#### Class II. Platini. or Platin. compounds.

##### Series 1. Platinamines, $\text{R}_2\text{Pt}(\text{NH}_3\text{R})_2$

These compounds are formed by the addition of  $\text{Cl}$ ,  $\text{Br}$ , or  $\text{I}$  to platosamines, or by the action of such oxidisers as  $\text{HNO}_3\text{aq}$  on platosamines; they are generally changed to platindiammines by heating with  $\text{NH}_3\text{Aq}$ , and are reduced to platosamines by  $\text{SO}_2\text{aq}$ . The radicles in direct union with  $\text{Pt}$  are replaced with more difficulty than those in union with  $\text{NH}_3$ . The nomenclature is arranged to indicate, first, the nature of the radicles in direct union with  $\text{Pt}$ , and then those in direct union with  $\text{NH}_3$ .

##### I. Chloro-compounds $\text{Cl}_2\text{Pt}(\text{NH}_3\text{R})_2$

**CHLOROPLATINAMMINE CHLORIDE**  $\text{Cl}_2\text{Pt}(\text{NH}_3\text{Cl})_2$ . Formed by suspending platosamine chloride,

$\text{Pt}(\text{NH}_4\text{Cl})_2$ , in boiling water, and passing in Cl until the original citron-yellow particles are changed to microscopic yellow octahedra (Gerhardt a. Laurent, *C. R.* 30, 273), or until the liquid, which is yellow at first, begins to turn reddish. *Aqua regia*, or  $\text{KMnO}_4$  and  $\text{HClAq}$ , may be used instead of Cl (Odling, *C. N.* 21, 269, 289). A heavy, yellow, crystalline powder. S. 1 at  $0^\circ$ ; 3 at  $100^\circ$ . Unacted on by boiling conc.  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$ ; sol. boiling  $\text{KOH Aq}$  without evolution of  $\text{NH}_3$ ; sol.  $\text{NH}_4\text{Aq}$ , with formation of chloroplatinidiammine chloride,  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ . The Cl is ppd. as  $\text{AgCl}$  only after long boiling with  $\text{AgNO}_3\text{Aq}$  (Grimm, *A.* 99, 67).

#### CHLOROPLATINAMMINE NITRITE

$\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NO})_2$ . Ppd. in colourless rhombic plates by addition of excess of  $\text{HClAq}$  to solution of the nitrate-nitrite,  $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$ , which is formed by boiling platossamine nitrite,  $\text{Pt}(\text{NH}_3)_4(\text{NO})_2$ , with  $\text{HNO}_3\text{Aq}$ .

#### CHLOROPLATINAMMINE CHLORONITRITE

$\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})(\text{NO}_2)_2$ , is produced by the reaction of  $\text{K}_2\text{PtCl}_6$  and  $(\text{NO}_2)_2\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$ .

#### II. Hydroxyl compounds

$(\text{OH})_2\text{Pt}(\text{NH}_3)_2$ .

#### HYDROXYL PLATINAMMINE HYDROXIDE

$(\text{OH})_2\text{Pt}(\text{NH}_3)_2(\text{OH})_2$ . Yellow, lustrous crystals; by adding excess of  $\text{NH}_4\text{Aq}$  to a boiling solution of the nitrate-nitrite  $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$ , and allowing to cool. Scarcely sol. water; easily sol. dilute acids. Boiling  $\text{KOH Aq}$  does not evolve  $\text{NH}_3$ ; decomposes above  $130^\circ$ , giving off  $\text{NH}_3$  and  $\text{H}_2\text{O}$ , and leaving Pt (Gerhardt a. Laurent, *C. R.* 30, 273).

#### HYDROXYL PLATINAMMINE NITRATE

$(\text{OH})_2\text{Pt}(\text{NH}_3)_2(\text{NO}_3)_2$ , 2aq. Crystalline pp. by decomposing  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{Cl})_2$  by  $\text{AgNO}_3\text{Aq}$ . Not acted on by cold  $\text{HClAq}$ ; evaporation with  $\text{HNO}_3\text{Aq}$  produces  $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$  (G. a. L., *C.* 1; Cleve, *Bl.* [2] 7, 12; 17, 482).

#### HYDROXYL PLATINAMMINE SULPHATE

$(\text{OH})_2\text{Pt}(\text{NH}_3)_2\text{SO}_4$ , aq. Formed as a pale-yellow, hard crust of needle-shaped crystals, by decomposing  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{Cl})_2$  by  $\text{Ag}_2\text{SO}_4$ . Evaporation with  $\text{H}_2\text{SO}_4\text{Aq}$  produces the sulphate-sulphate,  $\text{SO}_4\text{Pt}(\text{NH}_3)_2\text{SO}_4$ , 3aq; when  $\text{HClAq}$  is used,  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2\text{SO}_4$  and  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{Cl})_2$  are produced (Cleve, *l.c.*).

The following salts of this series have also been isolated: *Bromo-bromide*,  $\text{Br}_2\text{Pt}(\text{NH}_3)_2(\text{Br})_2$  (Cleve, *l.c.*); *bromo-nitrite*,  $\text{Br}_2\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$  (Cleve, *l.c.*); *iodo-iodide*,  $\text{I}_2\text{Pt}(\text{NH}_3)_2(\text{I})_2$  (Cleve, *l.c.*); *nitrate-nitrite*,  $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NO}_2)_2$ ; *nitrate-chloro-nitrite*,  $\text{NO}_3\text{ClPt}(\text{NH}_3)_2(\text{NO}_2)_2$  (Cleve, *l.c.*); *sulphate-sulphate*,  $\text{SO}_4\text{Pt}(\text{NH}_3)_2\text{SO}_4$ , 3aq (Cleve, *l.c.*).

**Series 2. Platinidiammines.**  
 $\text{R}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{R})_2$ . Generally formed by action of Cl, Br, I, and other oxidisers on platodiammines. A large number of these compounds is known. R attached directly to Pt may be the same as, or different from, R united directly to  $\text{NH}_3$ . The nomenclature is similar to that of the platinamine series. The radicles in direct union with Pt are removed with more difficulty than those united with  $\text{NH}_3$ .

#### I. Chloro compounds

$\text{Cl}_2\text{R}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{R})_2(\text{NH}_3)_2$ , where the R's may be the same or different.

#### CHLOROPLATINIDIAMMINE CHLORIDE

$\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ . By passing Cl into a fairly conc. boiling solution of platodiammine chloride,  $\text{Pt}(\text{NH}_3)_4(\text{NH}_4\text{Cl})_2$ , till the liquid begins to turn red (Raewsky, *A. Ch.* [3] 22, 278); also by dissolving chloroplatinamine chloride,  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{Cl})_2$ , in  $\text{NH}_4\text{Aq}$  (Gerhardt a. Laurent, *C. R.* 30, 273). Pale-yellow, crystalline powder; scarcely sol. cold water, sl. sol. boiling water.  $\text{HNO}_3\text{Aq}$  produces the *chloro-nitrate*  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})(\text{NO}_3)_2$ ; a little  $\text{AgNO}_3\text{Aq}$  produces the *chloro-hydroxyl-nitrate*  $\text{Cl}(\text{OH})\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})(\text{NO}_3)_2$ ; long boiling with  $\text{AgNO}_3\text{Aq}$  is needed to remove all Cl as  $\text{AgCl}$ . Reduced by  $\text{H}_2\text{S}$ , or action of Ag, to  $\text{Pt}(\text{NH}_3)_4(\text{NH}_4\text{Cl})_2$  (Thomsen, *J.* 1868, 278; Jørgensen, *J. pr.* [2] 33, 489). Forms double compounds with  $\text{PtCl}_2$  and  $\text{PtCl}_4$  (Reiset, *A. Ch.* [3] 11, 417; G. a. L., *l.c.*; Cleve, *Bl.* [2] 7, 12; 17, 482).

The other chloro compounds which are known are the following: *Chloro-nitrate*,  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})(\text{NO}_3)_2$  (Gros, *A. Ch.* [2] 69, 204; Raewsky, *A. Ch.* [3] 22, 278; Hadow, *C. J.* [2] 4, 345); *chloro-chloro-nitrite*,  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})(\text{NO}_2)_2$ ; *chloro-hydroxyl-chloride*,  $\text{Cl}(\text{OH})\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$  (Cleve, *l.c.*; Hadow, *l.c.*); *chloro-hydroxyl-carbonate*,  $\text{Cl}(\text{OH})\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2\text{CO}_3\text{H}_2\text{O}$  (Raewsky, *l.c.*; Gros, *l.c.*); *chloro-hydroxyl-chromate and dichromate*,  $\text{Cl}(\text{OH})\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2\text{CrO}_4$  and  $\text{Cl}(\text{OH})\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2\text{Cr}_2\text{O}_7$  (Cleve, *l.c.*); *chloro-hydroxyl-nitrate*,  $\text{Cl}(\text{OH})\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})(\text{NO}_3)_2$  (Raewsky, *l.c.*; G. a. L., *l.c.*; Cleve, *l.c.*); *chloro-chromate and dichromate*, and *chloro-sulphate*,  $\text{MCrO}_4$ ,  $\text{MCr}_2\text{O}_7$ , and  $\text{MSO}_4$ , where  $\text{M} = \text{Cl}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$  (Cleve, *l.c.*).

**II. Bromo compounds.** The following members of this class have been isolated (Cleve, *l.c.*); *bromo-bromide*,  $\text{MBr}_2$ ; *bromo-chloride*,  $\text{MCl}_2$ ; *bromo-dichromate*,  $\text{MCr}_2\text{O}_7$ ; *bromo-nitrate*,  $\text{M}(\text{NO}_3)_2$ ; *bromo-phosphate*,  $\text{M}(\text{PO}_4)_3$ , 2aq (in these formulæ  $\text{M} = \text{Br}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ ); *bromo-chloro-chloride*,  $\text{BrClPt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ ; *bromo-hydroxyl-chloride and nitrate*,  $\text{MCl}_2$  and  $\text{M}(\text{NO}_3)_2$ , where  $\text{M} = \text{Br}(\text{OH})\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ .

**III. Hydroxyl compounds.** *Hydroxyl-nitrate and sulphate*,  $\text{M}(\text{NO}_3)_2$  and  $\text{MSO}_4$ , where  $\text{M} = (\text{OH})_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ .

**IV. Iodo compounds.** *Iodo-iodide*,  $\text{MI}_2$ ; *iodo-nitrate*,  $\text{M}(\text{NO}_3)_2$ ; *iodo-sulphate*,  $\text{MSO}_4$ ; where  $\text{M} = \text{I}_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ .

**IV. Carbonato compounds.** *Carbonato-bromo-carbonate*, *carbonato-chloro-carbonate*, and *carbonato-nitrate-carbonate*,  $\text{Br}_2(\text{CO}_3)_2\text{R}$ ,  $\text{Cl}_2(\text{CO}_3)_2\text{R}$ , and  $(\text{NO}_3)_2\text{CO}_3\text{R}$ , where  $\text{R} = 2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2(\text{CO}_3)_2$ .

**V. Nitrate compounds** (Cleve, *l.c.*; Gerhardt a. Laurent, *C. R.* 30, 273):

$(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ , 2aq;  
 $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ ;  
 $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2\text{CrO}_4$ ;  
 $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2\text{Cr}_2\text{O}_7$ ;  
 $\text{OH}(\text{NO}_3)\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ ;  
 $\text{Cl}(\text{NO}_3)\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2\text{SO}_4$ ;  
 $\text{Cl}(\text{NO}_3)\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ .

**VI. Nitrito compounds** (Cleve, *l.c.*; Hadow, *C. J.* [2] 4, 345):  
 $(\text{NO}_2)_2\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ ;  
 $\text{I}(\text{NO}_2)\text{Pt}(\text{NH}_3)_2(\text{NH}_4\text{Cl})_2$ .

## VII. Sulphato-compounds (Cleve, l.c.):

## Series 3. Platinisemidiammines,

$\text{R}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{R})\text{R}$ . These compounds are isomeric with the platinammines,  $\text{R}_2\text{Pt}(\text{NH}_3\text{R})_2$ . They are generally formed by oxidising the platosemidiammines,  $\text{Pt}(\text{NH}_3\text{NH}_2\text{R})\text{R}$ .

## CHLOROPLATINISEMIDIAMMINE CHLORIDE

$\text{Cl}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})\text{Cl}$ . By chlorinating platosemidiammine chloride,  $\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})\text{Cl}$ , by  $\text{Cl}$  or *aqua regia* (Cleve, l.c.). Orange, crystalline powder; S. 35 at 0°, 1-52 at 100°. Not acted on by conc.  $\text{H}_2\text{SO}_4$  or alkali solutions.

The following salts of this series are known (Cleve, l.c.):

## Series 4. Platinimonomdiammines,

$\text{R}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{R})(\text{NH}_3\text{I})$ . Of this series the following have been isolated (Cleve, l.c.): *bromo-nitrate*,  $\text{Br}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{NO}_2)(\text{NH}_3\text{NO}_2)$ ; *bromo-sulphate*,  $\text{Br}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{SO}_3)(\text{NH}_3\text{NO}_2)$ ; *chloro-chloride*,  $\text{Cl}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{Cl})(\text{NH}_3\text{Cl})$ ; *hydroxyl-nitrate*,  $(\text{OH})_2\text{Pt}(\text{NH}_3\text{NH}_2\text{NO}_2)(\text{NH}_3\text{NO}_2)$ ; *hydroxyl-bromo-nitrate*,  $(\text{OH})\text{BrPt}(\text{NH}_3\text{NH}_2\text{NO}_2)(\text{NH}_3\text{NO}_2)$ ; *iodo-bromide*,  $\text{I}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{Br})(\text{NH}_3\text{Br})$ .

## Series 5. Platininitriammines,

$\text{R}_2\text{Pt}(\text{NH}_3\text{NH}_2\text{NH}_2)_2$ . This constitution is probably to be given to salts formed by electrolysis ammonium carbonate or carbonate solution, using electrodes of Pt (Drechsel, *J. pr.* [2] 20, 378; 26, 277; Gerdes, *J. pr.* [2] 24, 257). The salt formed as described is probably *carbonato-platininitriammine carbonate*,  $(\text{CO}_3)_2\text{Pt}(\text{NH}_3\text{NH}_2\text{NH}_2)_2\text{CO}_3$ . By the action of  $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$  and  $\text{HCl}$ , respectively, on this compound are obtained the *nitrate-nitrate*, *sulphato-sulphate*, and *chloro-chloride*,  $(\text{NO}_3)_2\text{M}(\text{NO}_3)_2$ ,  $\text{SO}_3\text{M}(\text{SO}_3)_2$  and  $\text{Cl}_2\text{M}(\text{Cl}_2)_2$ , where  $\text{M} = \text{Pt}(\text{NH}_3\text{NH}_2\text{NH}_2)_2$ .

## Class III. Diplatinum compounds.

## Series 1. Diplatodiammines,

(Blomstrand, *J. pr.* [2] 3, 207). Cleve (l.c.) gives to these compounds the formula

The following members of this series are known: *chloride*,  $\text{MCl}_2$ ; *hydroxide*,  $\text{M}(\text{OH})_2$ ; *nitrate*,  $\text{M}(\text{NO}_3)_2$ ; and *sulphate*,  $\text{MSO}_4$ ; where  $\text{M} = \text{Pt}(\text{NH}_3)_2$ .

## Series 2. Diplatindiammines,

The only compound of this series is the *chloride*  $\text{Cl}_2\text{Pt}(\text{NH}_3)_2\text{Cl}_2$ .

## Series 3. Diplatinammines,

The only compound of this series is the *iodide*  $\text{I}_2\text{Pt}(\text{NH}_3)_2\text{I}_2$  (Cleve, l.c.); by treatment with  $\text{HIAq}$ , the compound  $\text{PtI}_2(\text{NH}_3)_2$  and  $\text{PtI}_2(\text{NH}_3)_4$  are produced.

## Series 4. Diplatinitdiammines,

(Cleve, l.c.). The iodo-nitrate,

$\text{I}_2\text{Pt}(\text{NH}_3)_2(\text{NO}_3)_2$ , is formed by reacting on  $\text{I}_2\text{Pt}(\text{NH}_3)_2(\text{NO}_3)_2$  with  $\text{NH}_3\text{Aq}$  and treating the product with  $\text{HNO}_3\text{Aq}$ ; most of the other compounds of the series are formed from the iodo-nitrate. Various classes of compounds of this series are formed by varying the composition of the radicles, R; the nomenclature is similar to that used for the platinidiammines. The compounds which have been isolated are *bromo-nitrate*, *bromo-anhydronitrate*, and *bromosulphate*,  $\text{M}(\text{NO}_3)_2$ ,  $\text{M}(\text{NO}_3)_2\text{O}$ , and  $\text{M}(\text{SO}_3)_2\text{aq}$ , where  $\text{M} = \text{Br}_2\text{Pt}(\text{NH}_3)_2$ ; *hydroxyl-chloride*, *dischromate*, *phosphate*, and *sulphate*,  $\text{MCl}_2\text{aq}$ ,  $\text{M}(\text{CrO}_4)_2$ ,  $\text{M}(\text{HPO}_4)_2$  and  $\text{M}(\text{SO}_4)_2\text{aq}$ , where  $\text{M} = (\text{OH})_2\text{Pt}(\text{NH}_3)_2$ ; *iodo-iodide*, *anhydro-iodide*, *nitrate*, *anhydronitrate*, *phosphate*, and *sulphate*,  $\text{MI}$ ,  $\text{MI}_2\text{O}$ ,  $\text{M}(\text{NO}_3)_2\text{aq}$ ,  $\text{M}(\text{NO}_3)_2\text{O}$ ,  $\text{M}(\text{HPO}_4)_2$  and  $\text{M}(\text{SO}_4)_2$ , where  $\text{M} = \text{I}_2\text{Pt}(\text{NH}_3)_2$ ; *nitrate-nitrate*,  $(\text{NO}_3)_2\text{Pt}(\text{NH}_3)_2(\text{NO}_3)_2\text{aq}$ .

M. M. P. M.

**PLATINUMS, FULMINATING.** Various compounds of Pt, N, Cl, O, and H, all of which explode when heated, are formed by the action of  $\text{KOHAg}$  on  $(\text{NH}_3)_2\text{PtCl}_2$ , or by  $\text{ppg. Pt}(\text{SO}_3)_2$  with  $\text{NH}_3\text{Aq}$  and boiling the pp. with  $\text{KOHAg}$  (Proust, *Gehlen's J.* 1, 348; Döhreiner, *G. A.* 72, 194; Fourcroy a. Vauquelin, *Gehlen's J.* 1, 348; Davy, *S.* 19, 91). These compounds are classed together as *fulminating platinum*s. E. von Meyer (*J. pr.* [2] 18, 305) classifies according to the quantities of Cl they contain; all contain Pt and N in the ratio of equal numbers of atoms: *tetrachloro-compound*  $\text{Pt}_2\text{N}_2\text{Cl}_4\text{O}_4\text{H}_4$ , *trichloro-oxo-Pt*,  $\text{Pt}_2\text{N}_2\text{Cl}_3(\text{OH})\text{O}_4\text{H}_4$ , *dichloro-Pt*,  $\text{Pt}_2\text{N}_2\text{Cl}_2\text{O}_4\text{H}_4$ , *chloro-oxo-Pt*,  $\text{Pt}_2\text{N}_2\text{Cl}(\text{OH})\text{O}_4\text{H}_4$ . Tetrachloro-fulminating platinum is formed by adding  $\text{KOHAg}$  drop by drop to  $\text{Am}_2\text{PtCl}_6$  in the ratio 4:6  $\text{KOH}:\text{Am}_2\text{PtCl}_6$ , and washing the pp. by repeatedly boiling with acetic acid solution and then with water. At 150°  $4\text{H}_2\text{O}$  is given off; explosion occurs at a higher temperature. Dilute  $\text{H}_2\text{SO}_4\text{Aq}$  produces  $\text{H}_2\text{C}_2\text{O}_4$  and evolves  $\text{CO}$ . By treatment with  $\text{KOHAg}$ , or  $\text{NH}_3\text{Aq}$ , Cl is easily removed, a third Cl is removed with difficulty, but the fourth Cl remains unattacked.

M. M. P. M.

**PLUMBAGO.** A name sometimes given to graphite; v. **CARBON**, vol. i. p. 636.

**PLUMBATES.** Salts wherein  $\text{PbO}_2$  acts as acidic radicle, v. vol. iii. p. 132.

**PLUMBITES.** Salts wherein  $\text{PbO}$  acts as acidic radicle, v. vol. iii. p. 129.

**PLUMERIC ACID**  $\text{C}_{10}\text{H}_{16}\text{O}_8$ . [189°]. Occurs as calcium salt in the milky juice of *Plumeria acutifolia* (Oudemans, *A.* 181, 154). Minute crystals (from water), v. sol. alcohol and ether, sl. sol. cold water. Yields salicylic acid on fusion with  $\text{KOH}$ . Reduced by sodium-amalgam to crystalline 'hydroplumeric' acid  $\text{C}_{10}\text{H}_{16}\text{O}_8$ . —  $\text{K}_2\text{A}^{10}\text{aq}$ . —  $\text{Ca}(\text{HA}^{10})_2\text{aq}$ . S. 5 at 20°. —  $\text{CaH}_2\text{A}^{10}\text{aq}$ . S. 25 at 20°. —  $\text{Ca}_2(\text{HA}^{10})_2\text{aq}$ . —  $\text{Ag}_2\text{H}_2\text{A}^{10}\text{aq}$ . —  $\text{Ag}_2\text{HA}^{10}\text{aq}$ : needles (from water).

**PODOCARPIC ACID**  $C_{15}H_{25}O_2$ , i.e.

$C_{15}H_{25}O_2 \cdot C_2H_5Me(OH) \cdot CO_2H$ . Mol. w. 274. [188°].  $[a]_D = 136^\circ$ . Constitutes at least 90 p.c. of the resin found by de Vrij in the trunk of an old tree, *Podocarpus cupressina*, var. *imbricata* (Oudemans, A. 170, 213). Plates (from dilute alcohol), insol. water, v. sl. sol. benzene, v. e. sol. alcohol and ether. Dextrorotatory. Resolved at 300° into water and anhydride  $C_{15}H_{25}O$ . Yields methanthrene  $C_{15}H_{12}$  on distillation with zinc-dust. The Ca salt on distillation yields *p*-cresol, hydrocarpol, carpeno  $C_{15}H_{11}$ , and methanthrol  $C_{15}H_{12}O$ . Br added to its alcoholic solution forms  $C_{15}H_{25}BrEtO_2(EtOH)$  [above 80°], which gives off alcohol when heated for some time, leaving  $C_{15}H_{25}BrEtO_2$  [158°].

Salts.— $NaA'$  7aq. S. 33 at 21°. Needles.— $KA'$  3aq.— $KA'$  4aq.— $(NH_4)HA'$  2aq.— $BaA'$  3aq.— $BaA'$  8aq.— $BaA'$  9aq.— $BaA'$  15aq.— $BaC_2H_5O_2$  8aq.— $CaA'$  5aq.— $PbA'$  4aq.— $PbC_2H_5O_2$  4aq.— $PbHA'$  10aq.— $CuA'$  10aq.— $AgA'$  2aq.

Methyl ether  $MeA'$ . [174°]. Grains.

Ethyl ether  $EtA'$ . [146°]. Needles.

Acetyl derivative  $C_{15}H_{25}AcO_2$ . [152°]. Small needles (from dilute alcohol).

Nitropodocarpic acid  $C_{15}H_{25}(NO_2)_2O_2$ . [205°]. Formed, as well as the di-nitro-acids, by the action of  $HNO_3$  (S.G. 1.34). Small crystals, insol. water, m. sol. hot alcohol. May be reduced to unstable amido-podocarpic acid, which forms  $C_{15}H_{25}NO_2HCl$  1aq.

Salts.— $(NH_4)_2C_{15}H_{25}NO_2$  4aq.— $K_2C_{15}H_{25}NO_2$  5aq. Red needles with green lustre, v. sol. water.— $NaC_{15}H_{25}NO_2$  9aq. Scarlet plates.— $BaC_{15}H_{25}NO_2$  7aq. Red needles.— $BaC_{15}H_{25}NO_2$  3aq.— $BaA'$  4aq: yellow needles, sl. sol. water.— $CaC_{15}H_{25}NO_2$  4aq: orange needles.

Di-nitro-podocarpic acid  $C_{15}H_{25}(NO_2)_2O_2$ . [203°]. Pale-yellow crystals, insol. water, m. sol. alcohol.—Salts:  $K_2C_{15}H_{25}N_2O_2$  6aq. Crimson needles, with green reflex.— $BaC_{15}H_{25}N_2O_2$  4aq.— $Ag_2O$ ,  $H_{16}N_2O_2$  4aq: orange pp.

Sulphopodocarpic acid  $C_{15}H_{25}(SO_3H)O_2$  8aq. Got by warming with  $H_2SO_4$ . Amorphous mass. Salts:  $NaA'$  7aq: easily soluble rosettes.— $Ba(HA'')_2$  6aq.— $BaA'$  8aq: white laminae.— $CaA'$  7aq: thin laminae.

Hydrocarpol  $C_{15}H_{25}O$ . (220° in vacuo). A product of the distillation of calcium podocarpate. Viscid oil, v. sol. alcohol and ether. Yields *p*-cresol, carpeno, and methanthrol  $C_{15}H_{12}O$  [122°] when distilled. Methanthrol is crystalline, sol. KOHAq.

**PODOPHYLLIN**. The resin extracted from the root of *Podophyllum peltatum* (Guarreschi, B. 12, 683; G. 10, 16; Busch, Ph. [3] 8, 443; Senier a. Lowe, Ph. [3] 8, 445). It contains bitter and physiologically active 'picropodophyllin' crystallising in needles [200°–210°], and several resins, e.g. 'podophyllo-querceetin' [247°–250°] and 'podophyllinic acid' (Podwissotzky, Ph. [3] 12, 1011).

**POLYCHROÏTE** v. **SAPPHRON**.

**POLYMERISM**; a term generally applied to the phenomena of the existence of more than one substance having the same composition, and related in properties, but with different molecular weights; v. **ISOMERISM**, vol. iii. pp. 79–81.

M. M. P. M.

**POLYPORIC ACID**  $C_{15}H_{25}O_2$ . [above 300°].

Occurs in a fungus belonging to the genus *Polyporus*, which grows on the bark of diseased or dead oaks. The fungus is yellow, but is turned violet by ammonia (Stahlschmidt, A. 187, 177; 195, 365). Bronzed tables (from alcohol), insol. water, ether, benzene,  $CS_2$ , and HOAc, sl. sol. chloroform and alcohol. Alkalis form purple solutions, decolourised by zinc-dust. Yields a tetrahydride when boiled with conc. KOHAq. Yields benzene on distillation with zinc-dust. Conc.  $HNO_3$  forms  $C_{15}H_{11}(NO_2)_2O_2$  [230°].  $KClO_3$  and  $HCl$  give  $C_{15}H_{11}Cl_2O_2$  [108°] and  $C_{15}H_{11}Cl_2O_2$  [110°].

Salts.— $K_2A''$  2aq: purple monoclinic crystals.— $NaA''$  2aq: violet needles.— $(NH_4)_2A''$  2aq.— $BaA''$  4aq.— $BaA''$  2aq.— $SrA''$  4aq.— $SrA''$  4aq.— $CaA''$  3aq: pale-violet needles.  $MgA''$  3aq.— $AgA''$ : insoluble pp.

Methyl ether  $MeA''$ . [187°].

Ethyl ether  $EtA''$ . [134°]. Needles.

Diacetyl derivative  $C_{15}H_{25}Ac_2O_2$ . [205°]. Yellow needles, sl. sol. alcohol.

Hydride  $C_{15}H_{12}O_2$ . [163°]. Formed, together with the acid  $C_{15}H_{25}O_2$  [156°] which yields  $AgA''$  by boiling polyporic acid with conc. KOHAq. White crystalline powder (from hot water), sol. alcohol.— $NaA''$  4aq.— $BaA''$ .— $MnA''$  6aq.— $AgA''$ : crystalline pp.

**POPPY OIL**. The oil expressed from the seeds of *Papaver somniferum* contains glycerides of linoleic, stearic, and palmitic acids (Oudemans, J. 1858, 304; 1863, 333; cf. Mulder, J. 1865, 323).

**POPULIN** is the Benzoyl derivative of SALICIN.

**PORPHYRINE**  $C_{20}H_{16}N_4O_2$ . [97°]. Occurs, together with alstonine and alstonidine, in the bark of *Alstonia constricta* (Hesse, A. 205, 366). White amorphous substance, sol. alcohol, ether, and chloroform. Conc.  $H_2SO_4$  gives a purple solution. Its acid solutions exhibit blue fluorescence.— $B'H_2PtCl_4$  4aq.

**POTASH**. *Potassium hydroxide*, q. v., p. 302.

**POTASSIUM**. K. At. w. 39.04. Mol. w. probably 39.04 (Ramsay, C. J. 55, 521; v. *infra*). M.P. 58° (Quincke, P. 135, 642); 62.5° (Bunsen, A. 125, 368). B.P. 719°–731° (Carnelley a. Williams, C. J. 35, 563); 667° (Perman, C. J. 55, 326). S.G. 865 at 15° (Gay-Lussac a. Thénard); 875 at 13° (Baumhauer, B. 6, 655). V.D. not known with certainty; v. *infra*, molecular weight. S.H. from –78° to +10°–166 (Regnault, A. Ch. [3] 26, 286). C.E. (linear, 0°–50°) 00008415 (Hagen, Verhandl. d. physikal. Ges. zu Berlin, 1882, No. 13). Volume at  $t^\circ$ –vol. at 0° ( $1 + 00023935t + 00000629325t^2$ ) for interval 10° to 95° (Hagen, L.c.). E.C. at 0° (Hg at 0° = 1) 11.23; at 100° (liquid) 5.586 (Matthiessen, P. 100, 177). Refraction-equivalent 7.51 (Kanonnikoff, J. R. 1884 (1), 119). The emission-spectrum is characterised by a line  $K_\alpha$  in the extreme red, and a line  $K_\beta$  in the violet; for measurements of all the chief lines v. B. A. 1884, 436; for the absorption-spectrum v. Roscoe a. Schuster, C. N. 29, 268. H.C. [ $K^2O$ ] = 66,050 (Woods, P. M. [4] 2, 288).

*Occurrence*.—Compounds of K are widely distributed in large quantities. *Felspar, mica, &c.*, contain silicates of this metal; *carrollite, sylvine, &c.*, contain KCl; *alum-stone* and other

minerals contain  $K_2SO_4$ ; *saltpetre* is chiefly  $KNO_3$ . Sea-water contains c. .5 to .7 g. KCl per litre. Potassium salts, e.g. acid tartrate and oxalate, are found in plants. Animals contain salts of K, chiefly phosphate and chloride.

*Historical.*—Potash was decomposed by Davy (T. 1808. [1] 5) in 1807, by passing the electric current from a Volta-pile of 200 plates, through a piece of potash placed in a Pt basin. Gay-Lussac & Thénard, in 1808, reduced potash and obtained the metal, by heating it to whiteness with iron filings (A. Ch. 65, 325). In the same year Curaudan (A. Ch. 66, 97) showed that charcoal could be used instead of iron. Brunner (S. 88, 517) made this process applicable on the large scale, and B.'s method was modified by several workers, especially by Donny & Mareska (A. Ch. [3] 35, 147).

*Formation.*—1. By electrolysis KOH. The most effective method is to place a little conc. KOH aq, with pieces of solid KOH in it, in a Pt basin, to connect this with the negative pole of a powerful battery, to pour a little Hg into the basin, and place therein the wire from the positive pole. The K which is thus formed amalgamates with the Hg; the amalgam, after drying, is heated in a small retort, along with a little mineral oil, which drives out the air, and the K remains when the Hg has been distilled off.—2. By electrolysis a molten mixture of KCl and CaCl<sub>2</sub> in the ratio 2KCl:CaCl<sub>2</sub>. Temperature is arranged so that a solid crust remains on the surface of the molten mixture. Electrodes of gas-coke are used. After electrolysis the mixture is allowed to cool for twenty minutes, and the contents of the crucible are scraped out under petroleum (Matthiessen). Linnemann electrolyses molten KCN (J. pr. 73, 415).—3. By heating KOH to redness with iron filings or charcoal.—4. By heating an intimate mixture of  $K_2CO_3$  and C, or a mixture of  $K_2CO_3$  or KOH, C, and very finely-divided iron (Castner, C. N. 54, 218).—5. By heating sulphide of K with iron filings (Dolbear, C. N. 26, 33).—6. By heating potash with sodium under petroleum to c. 170° (Williams, C. N. 3, 21).—7. By the action of Na on dry molten K acetate (Wanklyn, C. N. 3, 66).

*Preparation.*—An intimate mixture of  $K_2CO_3$  and C is formed by heating cream of tartar (K-H tartrate) in a closed crucible. The mixture is then strongly heated in an iron bottle, connected with a flat receiver about 30 centim. long, 12 centims. wide, and 6 centims. from the inner surface of one side to that of the other; this receiver is made of two pieces of sheet-iron (about 4 mm. thick) screwed together, and has an opening at the end farthest from the retort, to allow the escape of CO. The reaction may be represented thus:  $K_2CO_3 + 2C = 2K + 3CO$ . The K distils over and condenses in the receiver; when full the receiver is removed, plunged under mineral oil and there opened, and the K is removed by a chisel. K combines with CO at a red heat to form a black, very explosive substance; the more rapidly the distilled K is cooled the less of this explosive compound is formed. The distilled metal is purified by wrapping it, when under oil, in a piece of linen, heating the oil to c. 65°, and pressing the molten K through the linen; the metal is then redistilled, from an iron bottle, into a copper tube

partly filled with mineral naphtha, and having an opening through which an iron rod may be passed to clear the tube which carries the K from the bottle into the receiver (Donny & Mareska, A. Ch. [3] 35, 147). Castner (C. N. 54, 218) uses as reducer a mixture of C and a metallic carbide, or a mixture of very finely-divided metal and C (conveniently prepared by heating a mixture of  $Fe_2O_3$  and tar in a covered vessel), and heats in an iron crucible with an exit-tube passing through the lid. The reaction, using KOH, Fe, and C, may be formulated as  $3KOH + Fe + 2C = 3K + Fe + CO + CO_2 + 3H_2$ .

*Properties.*—A silver-white, lustrous metal. As soft as wax at ordinary temperatures, brittle at 0°, melts at c. 60°. Boils when heated in a stream of H to c. 700°, and forms a bright-green vapour. A sublimate, in a very thin film on glass, shows a rich purple colour in transmitted light (Dudley, C. N. 66, 163; Newth, N. 47, 55). Crystallises in quadratic octahedra, which have a greenish-blue sheen. These crystals are obtained by melting K in a glass tube, narrowed at one place, and filled with coal-gas, and allowing the semi-solidified metal to flow slowly through the constricted part of the tube (Long, C. J. 13, 122). Sol. liquid  $NH_3$ , forming a blue liquid, from which the metal is obtained by allowing the  $NH_3$  to evaporate (Seeley, C. N. 23, 169; v. POTASSAMMONIUM, p. 299). Combines very rapidly with O; on exposing a freshly-cut surface to air, oxidation occurs at once. Decomposes cold water rapidly. K must be kept under a liquid free from O, such as mineral naphtha or rock-oil.

The atomic weight of K was determined by Berzelius, Penny, Marignac, Pelouze, Millon, Faget, and Maumené, from 1813 to 1846, by reducing  $KClO_3$ ,  $KClO_4$ , and  $KIO_3$  to KCl and KI, and by converting KCl, KBr, and KI to AgCl, AgBr, and AgI. The researches of Stas, in 1860 and 1865, have determined the at. w. with great accuracy. Stas heated  $KClO_3$ , thus getting KCl, decomposed KClO<sub>3</sub> by  $HCl$  aq, determined the ratio of KCl and KBr to Ag required for complete ppn., converted KCl into  $KNO_3$ , and KBr into AgBr, and determined the ratio of KBr to  $AgNO_3$  required for ppn. (Stas, Rech. 69, 70, 91, 118; Nouv. R. 244, 303).

The molecular weight of K is not known with certainty. Dewar & Dittmar (C. N. 27, 121) and Dewar & Scott (Pr. 29, 206, 490) determined the V.D. of K at c. 1000°; the earlier results pointed to a mol. w. of c. 90, and the later numbers to a value c. 45. V. Meyer (B. 13, 391) showed that the results were untrustworthy, as vapour of K attacks glass vessels. It has also been shown that vessels of Cu, Ag, Pt, or Fe cannot be used (Rieth, B. 4, 807; Meyer, l.c.). Ramsay (C. J. 55, 521) attempted to find mol. w. of K by dissolving in Hg, and finding the decrease of the vapour-pressure of Hg thereby produced. Assuming the mol. w. of liquid Hg to be 200, and also assuming that equal vols. of dilute solutions contain equal numbers of molecules, the results gave mol. w. of K as 29.1 and 30.2; it seems probable that the mol. of K is monatomic.

The only compound of K whose V.D. has been determined is KI; in this molecule the atom of K is monovalent.

K is a very strongly positive element. In all

its compounds it reacts as a metal, and does not enter into the composition of any negative radicles. K forms very few basic salts, and no oxyhaloid compounds; its halide compounds are very stable towards heat. K is closely related to Cs, Li, Na, and Rb (v. ALKALIS, METALS OF THE, vol. i. p. 114).

**Reactions.**—1. Heated in dry air or oxygen,  $K_2O$  and  $K_2O_2$  are formed (v. *Oxides*, p. 304).—2. At about  $300^\circ$  K absorbs hydrogen readily, probably forming  $KH$  (v. *Hydride*, p. 301).—3. Combines with chlorine, bromine, and iodine when heated (v. *Chlorides, bromides, iodides*, pp. 299, 300, 302).—4. Forms compounds with sulphur, selenium, and tellurium when heated (v. *Sulphides, selenides, tellurides*, pp. 305, 306).—5. Combines with phosphorus (v. *Phosphide*, p. 305).—6. Alloys with several metals (v. *Alloys, infra*).—7. Reacts rapidly with water, forming  $KOH$  and  $H_2$ .—8. Heated with hydrogen sulphide forms  $KHS$  (v. *Hydrosulphide*, p. 302).—9. Dissolves in liquid ammonia (Seeley, *C. N.* 23, 169; v. *infra*, POTASSIUMAMMONIUM). Heated in dry ammonia gas,  $KNH_2$  is formed (v. *Amide, infra*).—10. Combines with carbon monoxide to form  $KCO$  (v. *Carbonyl compound*, p. 300). At red heat decomposes  $CO$  with separation of C.—11. Decomposes carbon dioxide, and nitrous and nitric oxide, when strongly heated with these compounds.—12. Reacts with moist carbon dioxide to form  $K_2CO_3$  and  $HCO_2K$  (Kolbe a. Schmitt, *A.* 119, 251).—13. Decomposes silica and boric acid, when heated with these compounds, probably forming silicide and boride (q. v., pp. 299, 305).

**Potassium, alloys of.** Alloys of K with most metals are known; K alloys easily with the more fusible metals. The alloys generally oxidise in air, and decompose cold water. K forms amalgams with Hg; according to Joannis (*C. R.* 113, 795),  $Hg_{15}K$  is formed by letting potassiumammonium (q. v.) in liquid  $NH_3$  drop on to Hg. For polarisation of K amalgam in  $KCl$  aq against Zn amalgam v. Le Blanc, *Z. P. C.* 5, 467. For supposed alloy with  $NH_3$ , v. *infra*, POTASSIUMAMMONIUM.

**Potassium, aluminate of;** v. vol. i. p. 141.

**Potassium amide,  $KNH_2$ .** Gay-Lussac a. Thénard (*G. A.* 29, 135; 32, 23) obtained dark olive-green crystals by heating K in dry  $NH_3$ . Baumert a. Landolt (*A.* 111, 1) confirmed G. a. T.'s formula  $KNH_2$ . The compound is formed by passing dry  $NH_3$  into a flask of c. 50 c.c. capacity, fitted with a cork carrying an inlet and exit tube, quickly throwing in pieces of K, continuing the passage of  $NH_3$ , and heating very gently till the metal just ceases to dissolve in the greenish-blue liquid that is formed; on cooling, a yellowish-brown solid is obtained.  $KNH_2$  is a non-conductor of electricity. Melts at a little over  $100^\circ$ , at a higher temperature  $NH_3$  is given off, along with H and N, and  $K_3N$  remains (v. POTASSIUM NITRIDE, p. 304). Burns when heated in O, or heated to redness in air, giving N and  $KOH$ ; decomposes in moist air to  $KOH$  and  $NH_3$ ; must, therefore, be kept under rock oil. Reacts energetically with water, giving  $NH_3$  and  $KOH$  aq.

**Potassium-ammonium or Potassiumammonium.** By evolving dry  $NH_3$  from  $AgCl \cdot xNH_3$ , in a

Faraday tube containing K in the other end, Weyl (*P.* 121, 697) obtained a substance which he regarded as an alloy, or compound, of K and  $NH_4$ . Seeley (*C. N.* 23, 169) regarded the blue liquid formed by dissolving K in liquid  $NH_3$  as a solution, inasmuch as K was obtained again when the  $NH_3$  was allowed to evaporate. Joannis (*C. R.* 109, 900, 965; 110, 238) examined the vapour-pressures of a solution of K in liquid  $NH_3$ , and also the thermal phenomena attending the formation of the solution. He found the vapour-pressure to decrease till a certain value was reached, when it became constant, provided temperature was not changed; on removal of more  $NH_3$ , a copper-red solid separated, and thereafter  $NH_3$  was given off at constant pressure, till only K remained. This last part of the process was regarded by J. as a dissociation of  $NH_4K$ ; analysis showed this ratio ( $NH_4K$ ) to be always attained when the final part of the change commenced. The heat of formation of  $NH_4K$  is given by J. as 6,300 when  $NH_3$  is gas and K solid, and as 1,900 when  $NH_3$  is liquid and K solid. Joannis (*C. R.* 113, 795) found that  $NH_4K$  in liquid  $NH_3$  is decomposed by Sb, Pb, and Hg, but not by Al, Cu, Ag, or Zn; by dropping the liquid on to Hg, and washing the product with liquid  $NH_3$ , he obtained a crystalline amalgam  $Hg_{15}K$ .

By measuring the depression of the vapour-pressure of liquid  $NH_3$  by solution of K therein, J. concludes that the mol. formula of potassiumammonium is  $N_2H_4K_2$  (*C. R.* 115, 820).

**Potassium, antimonide of.** Probably  $SbK_3$ . A greyish-white, lustrous solid; decomposes water, giving  $KOH$ , Sb, and  $H_2$ . Formed by heating the elements together, or by fusing  $Sb_2O_3$  with  $K_2CO_3$  and C.

**Potassium, antimonates of;** v. vol. i. p. 296.

**Potassium, arsenates of;** v. vol. i. p. 309.

**Potassium, arsenites of;** v. vol. i. p. 306.

**Potassium, auricyanide of;** v. vol. ii. p. 332.

**Potassium, borates of;** v. vol. i. p. 529.

**Potassium, boride of.** The brown solid formed when boric acid is reduced by heating K may contain a compound of B and K.

**Potassium, borofluoride of;** v. vol. i. p. 526.

**Potassium, boronitride of.** By very strongly heating a mixture of 7 parts  $B_2O_3$  with 20 parts KCN, Dalmain (*J. pr.* 27, 422) obtained a white, infusible solid; insol. water or  $KOH$  aq.; decomposed by boiling *aqua regia*, leaving BN (vol. i. p. 527); heated in steam gave off  $NH_3$ , and left  $KOH$  and boric acid.

**Potassium, bromide of,  $KBr$ .** Formula probably molecular, from analogy of  $KI$ . Melts at  $699^\circ$  (Carnelley, *C. J.* 33, 279). S.G. 2.695 to  $2.72$  at  $4^\circ$  (Schröter, *P.* 106, 226);  $2.712$  at  $12.7^\circ$  (Clarke's *Tables of Spec. Gravities*, 2nd ed., 31);  $2.199$  fused (Quincke, *P.* 138, 141); v. also Spring (*B.* 16, 2724). S.H. ( $16^\circ$  to  $98^\circ$ ) 1.1322 (Regnault, *A. Ch.* [3] 1, 129). Vol. at  $40^\circ$ —vol. at  $0^\circ$  ( $1 + .00012602$ ) (Fizeau, *C. R.* 64, 814). S.  $58.48$  at  $0^\circ$ ,  $64.6$  at  $20^\circ$ ,  $74.62$  at  $40^\circ$ ,  $84.74$  at  $60^\circ$ ,  $93.46$  at  $80^\circ$ ,  $102.04$  at  $100^\circ$  (Kremers, *P.* 25, 119); Coppet (*A. Ch.* [5] 30, 411) gives S.  $54.43 + .5128t$  where  $t$  varies from  $-13.4^\circ$  to  $110^\circ$ . Gerlach (*Fz.* 8, 286) calculated the following from Kremers' data:

S.G. KBrAq			
5 p.c.	1.037	30 p.c.	1.256
10 "	1.075	35 "	1.309
15 "	1.116	40 "	1.366
20 "	1.159	45 "	1.430
25 "	1.207		

H.F. [K,Br] = 95,310; [K,Br,Aq] = 90,230 (Th. 8, 235). [KBr,O] = 84,060 (Th., l.c.).

**Formation.**—1. K and Br combine with production of much heat (v. Balard, Merz, a. Weith, B. 6, 1518).—2. By treating BrAq with iron filings and ppg. with  $K_2CO_3$ .—3. By neutralising HBrAq by KOHAq or  $K_2CO_3$  Aq, and evaporating.—4. By decomposing  $CaBr_2$  Aq by  $K_2SO_4$ , filtering after 12 hours, adding  $K_2CO_3$ , as long as turbidity is produced, filtering, and evaporating (Klein, A. 128, 237).

**Preparation.**—A moderately conc. solution of KOH, free from  $K_2CO_3$ , is prepared from pure  $K_2CO_3$  and pure CaO (v. *POTASSIUM HYDROXIDE*, p. 302); to this solution Br is added, little by little, till the liquid is slightly yellow; very finely powdered charcoal, equal to about one-tenth of the quantity of Br used, is added, and the liquid is evaporated to dryness ( $6KOH\text{Aq} + 3Br = 5KBr\text{Aq} + KBrO_3\text{Aq} + 3H_2O$ ); the dry residue is well powdered, and heated to dull redness in a closed crucible for some time ( $2KBrO_3 + 3C = 2KBr + 3CO_2$ ); the residue is extracted with warm water, the solution is filtered, and evaporated to the crystallising point.

**Properties and Reactions.**—KBr crystallises in very lustrous, white cubes, sometimes elongated to prisms or flattened to plates; it has a strongly saline taste. Easily sol. water, with considerable lowering of temperature; [KBr,Aq] = -5,080 (Th. 3, 235). Chlorine reacts with KBrAq to give  $KCl\text{Aq}$  and Br; Br is not set free by  $H_2SO_4$  containing  $N_2O_5$ , nor by  $KNO_3$  Aq + dil.  $H_2SO_4$  Aq. KBr heated with *potassium chromate* and *sulphuric acid* gives off Br; KCl under similar conditions gives  $CrO_2Cl_2$ . Conc. *sulphuric acid* produces HBr, Br, and  $SO_2$ ; the amount of HBr (the primary product of the reaction) thus decomposed varies very nearly in proportion to the quantity of  $H_2SO_4$  used; if the  $H_2SO_4$  is in such large excess that the water formed in the reaction causes no sensible dilution, only  $SO_2$  and Br are produced; by using dil.  $H_2SO_4$  Aq (a. 30 p.c.) a mere trace of Br is obtained, the products being almost wholly  $KHSO_4$  Aq and HBrAq (v. Addyman, C. J. 61, 94). *Hypochlorous acid* solution produces  $KCl\text{Aq}$  and  $KBrO_3\text{Aq}$ , with evolution of Br and Cl. *Potassium permanganate* solution has no action even when boiled; but Br is set free if a little  $H_2SO_4$  is added, even without warming, the decomposition being soon completed (Hempel, A. 107, 160). Fusion with *potassium chlorate* produces  $KBrO_3$ .

**Combinations.**—With many bromides of less positive metals to form double salts; some of these are best regarded as K salts of acids containing Br and a metal less positive than K, e.g.  $AuBr \cdot KBr$  is best looked on as  $KAuBr_2$  (v. the various metallic bromides). Also with *iodine bromide*, to form  $KBr \cdot IBr$  (Wells a. Wheeler, Am. S. [3] 48, 475). Also with some *metallic chlorides*; thus  $SbCl_3$  forms  $SbCl_3 \cdot 3KBr$  identical with  $SbBr_3 \cdot 3KCl$ , and therefore to be regarded as  $SbK_3Cl_3Br_3$  (Atkinson, C. J. 43, 240). Felt

(J. pr. [2] 39, 878) describes  $MgBr \cdot KBr \cdot 6aq$ , analogous to *carallite* ( $MgCl \cdot KCl \cdot 6aq$ ). Schiff (A. 228, 72) describes a compound with *arsenious oxide*  $KBr \cdot As_2O_3$ .

**Potassium tribromide**  $KBr_3$ . According to Berthelot (A. Ch. [5] 21, 370), orange crystals of this composition are formed by adding Br to KBrAq; no analyses are given. The substance decomposes rapidly. B gives [KBr,Br] = 2940.

**Potassium carbonyl compound of.** (*Carbonyl oxide potassium*.) The black solid formed in the preparation of K was thought by Berzelius (P. 4, 31) to be a carbide; Liebig (A. 11, 182) found that the same compound was formed by passing CO over K heated just to melting; Brodie (C. J. 12, 269) confirmed Liebig's result, and determined that one molecule CO is absorbed for each atom K; hence the empirical formula is probably KCO. This substance is extremely explosive; many serious accidents have occurred with it. If the CO used is quite dry, and the substance is washed rapidly in alcohol as soon as it is prepared, the residue is not nearly so explosive (Nietzki a. Benckiser, B. 18, 1833, where details of the method of preparation are given); probably the alcohol dissolves out unchanged K. *Potassium carbonyl* is a greyish solid; on standing in air it becomes yellowish and very explosive; it dissolves in water, with evolution of much gas (according to E. Davy [A. 23, 144] this gas contains  $C_2H_2$ ), and generally with combustion or explosion; heated to redness it is resolved into K and CO. By exposure to moist air, or by other processes of oxidation, a series of organic compounds is obtained (v. *Croconic acid*, vol. ii. p. 275; *Hexa-oxy-benzene*, vol. iii. p. 678; *Tetra-oxy-quinone*, vol. iii. p. 771; *Rumizonic acid*, this vol.).

**Potassium chloride of, KCl.** Formula probably molecular, from analogy of KI. Melts at  $73.1^\circ$  (Carnelley, C. J. 33, 279). S.G. 1.9775 at  $4^\circ$  (Playfair a. Joule, C. S. Mem. 2, 401); 1.9453 at  $15^\circ$  (Stolba, J. pr. 97, 503); 1.612 at M.P. (Braun, C. J. [2] 13, 31); 1.87 fused (Quincke, P. 135, 642); v. also Spring (B. 16, 272). S.H.  $14^\circ$  to  $99^\circ$  17295 (Regnault, A. Ch. [3] 1, 129; v. also Kopp, T. 155 [1] 71). Vol. at  $40^\circ$  = vol. at  $0^\circ$  ( $1 + .00011408$ ) (Fizeau, C. R. 64, 314). S. 32 at  $10^\circ$ , 33.4 at  $15^\circ$ , 34.7 at  $20^\circ$ , 37.4 at  $30^\circ$ , 40.1 at  $40^\circ$ , 42.8 at  $50^\circ$ , 45.6 at  $60^\circ$ , 48.3 at  $70^\circ$ , 51 at  $80^\circ$ , 53.8 at  $90^\circ$ , 56.6 at  $100^\circ$  (Mulder, Scheikund. Verh. 1864, 39); Coppet (A. Ch. [5] 30, 411) gives S. 28.51 + .2837 $t^\circ$ , where  $t^\circ$  varies from  $-11^\circ$  to  $109^\circ$ . S. at  $0^\circ$  in alcohol is given in following table (Gerardin, A. Ch. [4] 5, 139); where S.G. of alcohol is at  $0^\circ$ , and S +  $t^\circ$  is solubility at  $t^\circ$  (cf. Schiff, A. 126, 167):

Alcohol S.G.	S.	$t^\circ$	Alcohol S.G.	S.	$t^\circ$
.9904	23.2	.27	.9573	7.1	.162
.9848	19.4	.255	.9390	4.2	.125
.9793	15.7	.233	.8767	1.89	.061
.9726	11.9	.205			

Gerlach (Fr. 8, 231) gives the following data:

S.G. KClAq			
1 per cent.	1.0065	20 per cent.	1.1861
5 "	1.0325	24 "	1.1657
10 "	1.0658	24.9 "	1.1723
15 "	1.1004		

**H.F. [K, Cl]** = 105,610; **[K, Cl, Aq]** 101,170 (*Tk.* 8, 285). 30 parts KCl dissolved in 100 parts water at 18.2° lower the temperature to -6°, i.e. through 12.6° (Rüdorff, *B.* 2, 68). Solution of 1 g. KCl in 100 g. water freezes at -446°; saturated solution freezes at -10.9° (Rüdorff, *P.* 114, 63; 122, 337). Saturated solution boils at 108°.

**Occurrence.**—In small quantities in sea-water, and in some mineral springs. As chloride in *sylnite*; as double chloride, especially as *car-nallite*  $\text{KCl} \cdot \text{MgCl}_2 \cdot 6\text{aq}$ . In crude pearl ash, in plant ash, and in kelp.

**Formation.**—1. By the direct union of the elements; K burns in Cl at the ordinary temperature.—2. By heating K in HCl gas.—3. By passing Cl over KOH or KI heated to redness.—4. By the action of HClAq on KOH or  $\text{K}_2\text{CO}_3$ .—5. By decomposing various metallic chlorides by fusion with K.

**Preparation.**—1. Commercial KCl is prepared chiefly from *car-nallite*. The mineral is dissolved in warm water, heated by steam to c. 120°, and allowed to cool; at 60°–70°,  $\text{MgSO}_4 \cdot \text{aq}$ ,  $\text{CaSO}_4$ , and NaCl separate, and on further cooling c. 70 p.c. of the KCl is obtained; the crystals of KCl are washed with a little cold water, to remove NaCl and  $\text{MgCl}_2$ , and a product containing c. 95 p.c. KCl is thus obtained (for details v. *DICTIONARY OF APPLIED CHEMISTRY*).—2. Pure KCl is prepared by neutralising pure HClAq by pure KOH or  $\text{K}_2\text{CO}_3$ , evaporating to the crystallising point, and recrystallising from water.

**Properties.**—White salt, crystallising in cubes. Saline taste. Unchanged in air. Decrepitates when heated; melts at c. 740°, and volatilises at a higher temperature. Fairly sol. water or aqueous alcohol; insol. absolute alcohol, or conc. HClAq; sol. in 20 p.c.  $\text{K}_2\text{H}_2\text{O}_4\text{Aq}$ .

**Reactions.**—1. With acids, KCl generally gives K salt of the acid used and HCl.—2. Said to combine with *sulphuric anhydride*, and *chromic anhydride*, probably forming  $\text{SO}_4 \cdot \text{Cl} \cdot \text{OK}$  and  $\text{CrO}_3 \cdot \text{Cl} \cdot \text{OK}$  respectively (H. Rose, *P.* 38, 117).—3. Fused with *potassium*, in H, a blue substance is formed, supposed by H. Rose to be a subchloride (*P.* 120, 16). What is probably the same substance is formed during *electrolysis* of molten KCl (Bunsen & Kirchhoff, *P.* 113, 341).—4. For action of *water and oxygen*, in presence and absence of acids, v. Schulze, *J. pr.* [2] 21, 407.

**Combinations.**—1. With *sulphuric and chromic anhydrides*, v. *Reactions*, No. 2.—2. With *most metallic chlorides*; some of the compounds are best regarded as K salts of metal-containing acids, e.g.  $\text{KAuCl}_4$  (v. the different *metallic chlorides*).—3. With *iodine trichloride*, to form  $\text{KCl}_3\text{ICl}_4$ ; prepared by mixing KClAq and  $\text{ICl}_3\text{Aq}$ , by passing Cl into warm KClAq containing HCl, or by dissolving 1 part KIO, in 8 parts HClAq of S.G. 1.176, at 40°–50°. Forms lustrous yellow prisms, smelling of Cl; on heating gives Cl, KCl, and  $\text{ICl}_3$ ; with water forms KIO,; ether dissolves out  $\text{ICl}_3$  (Fihol, *J. Ph.* 25, 435, 506).—4. With *iodine monochloride*, to form  $\text{KCl}_3\text{ICl}$  (Wells & Wheeler, *Am. S.* [3] 43, 475).

**Potassium, cyanide of**; v. vol. ii. p. 346.

**Potassium, chromi-cyanide of**; **chromi-sulpho-cyanide of**; and **chromo-cyanide of**; v. vol. ii. p. 330.

**Potassium, cobalti- and cobalto-cyanide of**; v. vol. ii. p. 330.

**Potassium, ferrate and ferrite of**; v. vol. ii. p. 547.

**Potassium, ferri- and ferro-cyanide of**; v. vol. ii. pp. 339, 336.

**Potassium, fluorides of.** Two fluorides are known, KF, and  $\text{KHF}_2$  or  $\text{KF} \cdot \text{HF}$ .

**POTASSIUM FLUORIDE KF.** Formula probably molecular, from analogy of KI. Prepared by neutralising HFAq by  $\text{K}_2\text{CO}_3$  in a dish of Ag or Pt, evaporating to dryness, and heating till HF ceases to be given off. According to Berzelius (*P.* 2, 218), KF is obtained in crystals by slowly evaporating an aqueous solution at 35°–40° in a very shallow dish. Deliquescent; fusible; solution has alkaline reaction to litmus, and etches glass. Guntz (*A. Ch.* [6] 3, 5) says  $\text{KFAq}$  is neutral, but the salt is decomposed in solution and becomes alkaline. Evaporation of a very conc. solution gives  $\text{KF} \cdot 2\text{H}_2\text{O}$ , according to H. Rose. S.G. 2.451 (Bödeker); 2.096 at 21.5° (Clarke, *Am. S.* [3] 13, 291). Combines with HF to form  $\text{KF} \cdot \text{HF}$  (v. *infra*); with  $\text{BF}_3$  to form  $\text{KBF}_4$  (v. **POTASSIUM BOROFLUORIDE**, vol. i. p. 526); with  $\text{SiF}_4$  to form  $\text{K}_2\text{SiF}_6$  (v. p. 305); with  $\text{B}_2\text{O}_3$  to form  $2\text{KFB}_2\text{O}_4$ , obtained by dissolving  $\text{B}_2\text{O}_3$  in molten KF (Schiff, *A.* 228, 72); with  $\text{TeF}_6$  to form  $\text{KF} \cdot \text{TeF}_6$ , by evaporating  $\text{TeO}_3$  in HFAq with addition of  $\text{K}_2\text{CO}_3$  (Högborn, *B.* [2] 35, 60); and with many metallic fluorides.

**POTASSIUM-HYDROGEN FLUORIDE  $\text{KHF}_2$  or  $\text{KF} \cdot \text{HF}$ .** Prepared by dividing a quantity of HFAq into two equal parts, neutralising one, adding the other, and evaporating; also by evaporating KF in acetic acid. White cubes or four-sided tables; c. sol. water, almost insol. dil. HFAq. When heated gives HF, leaving KF. By electrolysis of HF containing  $\text{KHF}_2$ , F is obtained (v. **FLUORINE**, vol. ii. p. 561). Moissan (*C. R.* 105, 547) says that two other compounds of KF and HF are obtained by dissolving dry KF in liquid HF, and cooling; to these compounds he gives the formulae  $\text{KF} \cdot 2\text{HF}$  and  $\text{KF} \cdot 3\text{HF}$ . Guntz (*A. Ch.* [6] 3, 5) gives  $[\text{HF} \cdot \text{KF}] = 21, 100$ .

**Potassium, haloid compounds of.** The compounds KF, KCl, KBr, and KI are the chief halides of K; as KI has been gasified and the molecular weight corresponds with the simplest formula, it is probable that  $\text{KX}$  expresses the molecular composition of these halides. KI, also exists, but is decomposed by heat; and there are indications of the existence of  $\text{KBr}_2$ . KF combines with HF to form  $\text{KHF}_2$ , and, according to Moissan, also  $\text{KF} \cdot 2\text{HF}$  and  $\text{KF} \cdot 3\text{HF}$ .

**Potassium, hydride of, K.H.** The absorption of H by heated K was observed by Gay-Lussac & Thénard (*A. Ch.* 74, 203), and was confirmed by Jacquelin. Troost & Hautefeuille (*A. Ch.* [5] 2, 273) found that the absorption of H by K begins at c. 200° and becomes rapid at 350°–400°; if the action continues for some time 126 vols. H are absorbed by 1 vol. K. The product is brittle, and much resembles Ag amalgam; it is fusible without change in H or in *vacuo*; takes fire in contact with air; heated in *vacuo*, dissociation begins at 200° (for vapour pressures of H given off, v. **DISSOCIATION**, vol. ii. p. 398). The formula  $\text{K.H}$  requires 124.6 vols H to 1 vol. K.

**Potassium, hydrosulphide of, KHS** (*Potassium sulphhydrate*). Gay-Lussac & Thénard (*A. Ch.* 115, 185) obtained this compound by heating K in dry  $H_2S$  gas; it is more readily formed by heating  $K_2CO_3$  to redness in  $H_2S$  ( $H_2O$  and  $CO_2$  are given off) (Berzelius, *P.* 6, 438). By saturating KOHAq with  $H_2S$ , and evaporating the conc. solution over  $CaO$  or  $CaCl_2$  *in vacuo*, Schöns (P. 131, 380) obtained lustrous, rhombohedral crystals of  $2KHS.H_2O$ ; and by dehydrating this in a stream of dry  $H_2S$ , Sabatier (*A. Ch.* [5] 22, 5) obtained KHS as a yellow, amorphous solid. Prepared in the dry way, KHS appears reddish-black when molten, and white when cold; it crystallises in prisms; is very deliquescent, and reacts strongly alkaline; easily sol. in alcohol. Thomsen (*Th.* 3, 235) gives  $[K, S, H, Aq] = 65, 140$ . KHSAq gives off  $H_2S$  at  $70^\circ$ , according to Drechsel (*J. pr.* [2] 4, 20). When a current of an inert gas is passed through KHSAq,  $H_2S$  is given off, and  $K_2SAq$  remains (Gernez, *C. R.* 64, 606). Electrolysis produces H and KOH at the negative pole, and  $H_2S$  at the positive (Bunge, *B.* 3, 911). KHSAq dissolves S with evolution of  $H_2S$ ; it ppts.  $MnS$ , or  $PbS$ , from a neutral solution of a Mn or Pb salt, at the same time giving off  $H_2S$ . These reactions distinguish KHSAq from  $K_2SAq$ ; the latter does not give off  $H_2S$  while dissolving S or ppg.  $MnS$  or  $PbS$ . KHSAq dissolves several sulphides of the less positive metals, e.g. Sb, As, Sn, forming K thiosalts.

**Potassium, hydroxide of, KOH** (*Caustic potash. Potassium, or potassic, hydrate*). S.G. 2.1 (Dalton); 2.044 (Filhol, *A. Ch.* [3] 21, 415). H.F.  $[K, O, H] = 103, 170$ ;  $[K, O, H, Aq] = 116, 460$  (*Th.* 3, 235).

**Formation.**—1. By the reaction between K and  $H_2O$ , or  $K_2O$  and  $H_2O$ , followed by evaporation.—2. By boiling  $K_2CO_3$  Aq with  $CaO$ .—3. By adding powdered  $K_2SO_4$  to warm conc. BaOAq, evaporating, filtering, and again evaporating (Schubert, *J. pr.* 26, 117).—4. By heating  $KNO_3$  with 2-3 parts thin copper turnings, to redness, in an iron, or copper, crucible, extracting with water when cold, filtering from  $CuO$  and  $Cu_2O$ , and evaporating (Wöhler, *A.* 87, 373).—5. By heating 1 part  $KNO_3$  with 1 part  $Fe_2O_3$  in a closed crucible of Cu, H being passed in; treating with water, and drawing off the clear liquid, and evaporating it (Schulze, *Z.* 1861. 109). Evaporation of KOHAq should be performed in vessels of polished iron, or, better, of silver.

**Preparation.**—1. A solution of pure  $K_2CO_3$  in 10-13 parts water is boiled, in a dish of silver or polished iron, with milk of lime, added little by little, till a portion of the clear supernatant liquid gives no effervescence with an acid; rather more than half as much  $CaO$  is required as the weight of  $K_2CO_3$  taken; large excess of  $CaO$  should be avoided; water should be added as the boiling proceeds, because if the quantity of water is less than c. 10 times the quantity of  $K_2CO_3$ , used the KOHAq begins to decompose the  $CaCO_3$  formed, and the change of  $K_2CO_3$  to KOH stops (Liebig, *A.* 1, 124). When the change is completed, the vessel is closed, and, after a few hours, the clear liquid is drawn off by a syphon; the liquid is then rapidly evaporated in an iron vessel, allowed to stand for an hour or two, the vessel being closed, syphoned off from any pp. that has formed,

evaporated in a silver dish till the oily liquid thus produced begins to volatilise in white clouds, and cooled in an exsiccator. Impure KOH may be freed from all impurities, except KCl and traces of  $K_2CO_3$  and  $K_2C_2O_4$ , by dissolving in absolute alcohol, allowing to settle, draining off, and evaporating, at first on a water-bath, in a silver dish; the resinous matter which is produced is removed from the warm evaporated semi-solid mass, by a silver spatula, and the KOH is then poured out on to a plate of polished iron, or, better, of silver.

Graeger (*J. pr.* 96, 188) recommends to heat the  $K_2CO_3$  Aq used with  $Ag_2CO_3$ , to filter from  $AgCl$  and excess of  $Ag_2CO_3$ , to boil, in a silver dish, with pure  $CaO$  made by strongly heating pure  $CaCO_3$ , to filter the solution of KOH through pounded marble which has been washed with water till free from very fine particles, and to evaporate in a silver dish.—2. Water and benzene are placed in a silver dish, and small pieces of K, cut from the inside of a lump, are thrown in one by one; the K remains near the surface of separation of the two liquids, and reacts fairly slowly with the water. The benzene is removed by warming, and the aqueous solution of KOH is then evaporated to dryness.

**Properties.**—After fusion, KOH is a white, hard, brittle solid, often showing a fibrous texture. Melts below red heat, and volatilises at full redness in white pungent vapour. Very deliquescent; sol. water with production of much heat,  $[KOH, Aq] = 13, 290$  (*Th.* 3, 235). Easily sol. alcohol. Skeay (*C. N.* 36, 48) says KOH is very sl. sol. ether. Absorbs  $CO_2$  rapidly from the air, forming  $KHCO_3$ . KOH has a slight, but nauseous, odour, a strongly acid taste, and acts as a powerful cautery towards both animal and vegetable matter. KOHAq should be kept in glass vessels free from Pb, as it corrodes lead-glass; it attacks vessels of glass or porcelain when heated in them. To keep KOHAq free from carbonate, it is advisable to store it in bottles fitted with corks carrying a syphon-tube, and a rather wide tube filled with a mixture of equal parts  $CaO$  and  $Na_2SO_4$ , well rubbed together, dried over a flame, and passed through a sieve to remove fine powder; the air which enters through this mixture is quite free from  $CO_2$ .

KOHAq is strongly alkaline; the affinity of KOH in solution is large, about equal to that of NaOH and LiOH, and about 50 times greater than  $NH_4$  Aq (Ostwald). KOH saponifies ethereal salts, and ppts. most of the heavier metals as oxides or hydroxides from solutions of their salts.

The table on next page, given by Lunge, shows the composition of KOHAq of different S.G.

Expansion occurs when conc. KOHAq is diluted; Frankenheim (*J.* 1847-8. 69) gives  $V = 1 + .000415t + .00000577t^2$  as representing the volume of KOHAq S.G. 1.2738 at  $0^\circ$ , between  $13^\circ$  and  $100^\circ$ .

**Reactions.**—1. According to Deville (*C. R.* 45, 857), KOH is decomposed to K, O, and H by heating to white heat.—2. Strongly heated with non-volatile acidic anhydrides, water and potassium salts are formed.—3. Heated with potassium,  $K_2O$  and H are formed; heated with sodium under a liquid free from O, an alloy of K and Na

# POTASSIUM IODIDE.

is said to be formed (Williams, *Rep. Chim. pure*, 3, 177).—4. Iron decomposes KOH at white heat, forming Fe<sub>2</sub>O<sub>3</sub>, H<sub>2</sub>, and K<sub>2</sub>.—5. Molten KOH acts generally as an oxidiser: e.g. Fe, As, Sb, Pt, &c. form ferrate, arsenate, antimonate, and platinate of K; Cr<sub>2</sub>O<sub>3</sub> forms K<sub>2</sub>CrO<sub>4</sub> &c. Salts are generally decomposed by molten KOH, giving

K salts, and setting free the bases.—6. KOHq neutralises acids, forming salts.—7. KOHq decomposes most metallic salts in solution, ppg. oxides or hydroxides of the metals.—8. According to Schöne (A. 193, 241), addition of hydrogen peroxide to KOHq produces K<sub>2</sub>O<sub>4</sub> (v. Potassium tetroxide, p. 305).

**Combinations.**—1. With carbon dioxide, to form KHCO<sub>3</sub>.—2. With water, to form hydrates. Pickering (C. J. 63, 890) obtained KOH.H<sub>2</sub>O freezing at 143°, KOH.2H<sub>2</sub>O freezing at 35.5°, and KOH.4H<sub>2</sub>O freezing -32.7° (cf. Walter, P. 39, 192; Schöne, P. 131, 147). P. (l.c.) gives full data for freezing points of KOHq. Götting (B. 20, 1094) described two hydrates, 2KOH.9H<sub>2</sub>O and 2KOH.5H<sub>2</sub>O, obtained from an alcoholic solution of KOH containing some water; but in a later paper (B. 20, 1907) G. says that these hydrates contained alcohol besides water. 3. With methyl alcohol, to form 3KOH.5MeOH (Götting, B. 20, 1832). 4. With ethylic alcohol, to form KOH.2EtOH (Engel, C. R. 103, 155); decomposed by heating to EtOK, EtOH, and H<sub>2</sub>O.

**Potassium, iodides of.** Two iodides are known, KI and KI<sub>3</sub>.

**POTASSIUM IODIDE, KI.** Mol. w. 165.57. Melts at 631° (Carnelley, C. J. 33, 279). S.G. 8.059 (Playfair & Joule, C. S. Mem. 2, 401); 8.077 to 3.081 (Schröder, P. 106, 226); fused 2.437 (Quincke, P. 138, 141); v. also Spring (B. 16, 2724). V.D. 91.5 (Dewar & Scott, I. 29, 206); 84.6 at above 1300°, in N (Menschinger & Meyer, Z. P. C. 1, 157). S.H. (20° to 99°) .08191 (Regnault, A. Ch. [3] 1, 129). Vol. at 40° = vol. at 0° (1 + .00012796) (Fizeau, C. R. 64, 314). S. 132.1 at 5°, 136.1 at 10°, 140.2 at 15°, 144.2 at 20°, 152.3 at 30°, 160 at 40°, 168 at 50°, 176 at 60°, 184 at 70°, 192 at 80°, 201 at 90°, 209 at 100°, 218 at 110° (Mulder, *Scheikund. Verhandel.*, Rotterdam, 1864.162). Coppet (A. Ch. [5] 30, 411) gives S. at t° = 126.23 + .8088t, where t varies from -5.9° to 120°. S. in aqueous alcohol is given in following table. (Gerardin, A. Ch. [4] 5, 139); the values hold for 0° to 18°:

S.G. alcohol	S.	S.G. alcohol	S.
.9904	130.5	.9528	76.9
.9851	119.4	.9390	66.4
.9726	100.1	.9098	48.2
.9665	89.9	.8464	11.4
		.8322	6.2

H.F. [K, I] = 80,130; [K, I, Aq] = 75,020 (Th. 3, 235).

**Formation.**—1. By the direct union of K and I.—2. By neutralising HIAq by K<sub>2</sub>CO<sub>3</sub>, and evaporating.—3. I is added to water and iron filings till the iron is almost wholly dissolved, the solution is filtered, and K<sub>2</sub>CO<sub>3</sub> added so long as FeCO<sub>3</sub> ppts.; the liquid is filtered (if alkaline it is neutralised by HIAq) and evaporated, any Fe<sub>2</sub>O<sub>3</sub> which separates being filtered off (Baup, J. Ph. 9, 37, 122).—4. By adding I to KOHq, evaporating, heating with C, dissolving, filtering, and evaporating (v. Preparation).—5. BaI<sub>2</sub>Aq is formed by the action of I and water on BaS, and is decomposed by K<sub>2</sub>SO<sub>4</sub>; BaSO<sub>4</sub> is filtered off, and the liquid is evaporated. Liebig (A. 121, 222) used CaI<sub>2</sub> in place of BaI<sub>2</sub> (cf. Pettenkofer, A. 121, 225).

**Preparation.**—Moderately, but not too, conc. KOHAq, quite free from  $K_2CO_3$ , is prepared from  $K_2CO_3$  and CaO (v. POTASSIUM HYDROXIDE, *Preparation*, p. 802); I is added, little by little, to the slightly warm liquid till a slight yellow colour is produced; very finely powdered charcoal is now added, equal to  $c. \frac{1}{10}$  of the weight of I used, the liquid is evaporated quite to dryness, the residue is powdered, and heated, in a closed crucible, to dull redness for some time ( $6KOHAq + 6I = 5KIAq + KIO_3Aq + 3H_2O$ ;  $KIO_3 + 3C = KI + 3CO$ ). The contents of the crucible, when cold, are extracted with water, the liquid is filtered, neutralised by HIAq if alkaline, and crystallised. Morse & Burton (*Ann.* 10, 321) recommend to remove traces of  $KIO_3$  by boiling for some time with Zn amalgam and water, filtering, and crystallising; neither Zn nor Hg is found in the filtrate. The Zn amalgam is made by agitating zinc-dust with Hg in presence of tartaric acid solution, and washing with water.

**Properties.**—White cubes; non-deliquescent. Has a sharp taste. Solution in water is attended with fall of temperature; 140 pts. in 100 pts. water at  $10.8^\circ$  produce a fall to  $-11.7^\circ$  (Rüdorff, *P.* 136, 276).

**Reactions.**—1. Unchanged in dry air, but decomposed in ordinary air when exposed to sunlight (v. Downes & Blunt, *Pr.* 29, 319; Loew, *Fr.* 1870, 251). Air containing ozone also decomposes KI (Houzeau, *J.* 1858, 60).—2. Heated in air to  $230^\circ$ , some  $KIO_3$  is formed.—3. Heated in steam, I is evolved (Pettersson, *Fr.* 1870, 362) and HIAq formed (Schindler, *Mag. Pharm.* 31, 33).—4. Decomposed, with separation of I, and formation of KOH, by heating with lead dioxide, manganese dioxide, arsenic oxide, antimonious oxide, chromum trioxide, hydrogen peroxide, &c. (v. Weltzien, *A.* 138, 134).—5. Chlorine decomposes hot KI to KCl and I. KIAq with ClAq gives KClAq, and I; with excess of Cl, ICl<sub>3</sub> is formed and remains in solution, or combines with the KCl and separates as KCl<sub>3</sub>ICl<sub>3</sub>, according to the quantity of water present. Bromine acts similarly to Cl.—6. Nitrous acid solution sets I free; KNO<sub>3</sub> and dil. HClAq act in the same way (v. Price, *C. J.* 4, 155).—7. Conc. sulphuric acid, or nitric acid, decomposes KI when heated with it, giving sulphate or nitrate of K, and I; with  $H_2SO_4$ ,  $SO_2$ , and  $H_2S$  are also formed. Addition of conc.  $H_2SO_4$  to KIAq, or evaporation with  $HNO_3$ Aq, sets I free. If KIAq contains  $KIO_3$ , a few drops of a dilute acid suffice to give free I ( $5HIAq + HIO_3Aq = 3I_2 + 3H_2O$ ). *Aqua regia* sets I free from KIAq (for the delicacy of this reaction v. Harting, *J. pr.* 22, 46).—8. Heated with sulphuric anhydride,  $K_2SO_4$ ,  $SO_2$ , and I are formed (H. Rose, 39, 121).—9. Manganese dioxide and sulphuric acid produce I,  $MnSO_4$ , and  $K_2SO_4$ , when heated with KI.—10. KI fused with potassium-hydrogen sulphate gives  $K_2SO_4$ , and I.—11. Fusion with potassium chlorate produces  $KIO_3$ .—12. Heating with barium nitrate forms  $KIO_3$  and  $BaO$ . (Henry, *J. Ph.* 18, 845).—13. By heating with ammonium chloride, I, Aml, and KCl are formed.—14. Conc. potassium ferricyanide solution gives I and  $K_3FeCy_6$ Aq; on dilution the action is reversed (Mohr, *A.* 105, 57).—15. Heated with potassium borate,  $KIO_3$ , and a polyborate (? probably  $K_2B_4O_{10}$ ) are formed (Schiff, *A.* 228, 72).

**Combinations.**—1. With most iodides of less positive metals (v. various metallic iodides). Several of the compounds produced are best regarded as K salts of metal-containing acids (v. Remsen, *Am.* 11, No. 5).—2. With arsenious oxide to form  $KIAsO_3$  (Schiff, *A.* 228, 72).—3. With potassium ferricyanide, to form a very unstable compound,  $KI_3FeCy_6$  (Preuss, *A.* 29, 323; Mohr, *A.* 105, 57; Blomstrand, *J. pr.* [2] 3, 207; Kern, *C. N.* 33, 184).

POTASSIUM TRI-IODIDE  $KI_3$ . Dark-blue, lustrous needles; almost black by reflected light; melts at  $45^\circ$ ; S.G. 3.498 at  $c. 15^\circ$ ; by saturating KIAq with I, and evaporating over  $H_2SO_4$  (Johnson, *C. J.* 31, 249). Very deliquescent; in a little water some I is deposited; sol. alcohol, in a very small quantity water, and in saturated solution of I in KIAq. Agitation with  $CS_2$  of conc. KIAq saturated with I abstracts the dissolved I (Baudrimont, *C. R.* 51, 827). Jørgensen (*J. pr.* [2] 2, 347) found, however, that  $CS_2$  did not remove the I from an alcoholic solution of KI containing excess of I in ratio KI:2I, and that alcoholic KI completely decolourised solutions of I in  $CS_2$ .

POTASSIUM DI-IODIDE  $?KI_2$ . A solution of 3 pts. I in 4 pts. KI in water is said by Guyard (*Bl.* [2] 31, 297) to contain an unstable compound of this composition; with  $Pb(NO_3)_2$ Aq or  $Pb(C_2H_3O_2)_2$ Aq, this solution gives an almost black pp., said by G. to be  $PbI_2$ .

Potassium, iodobromide of. The compound  $KBr.IBr$  may be called iodobromide of potassium; v. POTASSIUM BROMIDE, *Combinations*, p. 300.

Potassium, iodochlorides of. The compounds  $KCl.ICl$ , and  $KCl_2.ICl$  may be called iodochlorides of potassium; v. POTASSIUM CHLORIDE, *Combinations* Nos. 3 and 4, p. 301.

Potassium, iridicyanide of; v. vol. ii. p. 332.

Potassium mangani- and mangano-cyanide of; v. vol. ii. p. 342.

Potassium, nitride of,  $K_3N$ . Formed by heating to redness  $KNH_2$  (v. POTASSIUM AMIDE, p. 299) in absence of O. A dark-grey, almost black, solid. Sublimes partially at white heat. Takes fire in air, with evolution of N; reacts with water to give KOHAq and  $NH_3$ .  $K_3N$  is a conductor of electricity. Combines with S and P (Gay-Lussac & Thénard, *A. Ch.* 65, 325).

Potassium, nitroprusside of; v. vol. ii. p. 341.

Potassium, osmocyane of; v. vol. ii. p. 343.

Potassium, oxides of. Two oxides have been certainly isolated,  $K_2O$  and  $K_2O_2$ ; there are indications of the existence of others.

Potassium oxide  $K_2O$  (Potassium monoxide). A mixture of  $K_2O$  and  $K_2O_2$  is formed by burning K in air; when K is burnt in a stream of dry O only  $K_2O$  is produced, but on strongly heating this product O is given off, and  $K_2O$  remains (Davy, *T.* 1808 [1] 5).  $K_2O$  is also formed by heating KOH and K in the ratio KOH : K; according to Beketoff (*Bl.* [2] 37, 491), K and KOH do not react. B. says that  $K_2O$  may be prepared by heating a mixture of  $K_2O$  and K in a silver dish. To prepare pure  $K_2O$  Kühnemann (*C. C.* 1864, 491) recommends to lead air, freed from  $CO_2$ , over K heated just to fusion; the K spreads out into a thin layer

is a greyish, non-lustrous solid; S.G. 2.656 (Karsten, S. 65, 394); melts at full red-heat, and volatilises at a very high temperature. Thomsen (*Th.* 3, 235) gives  $[K_2O, Aq] = 165,460$ .  $K_2O$  reacts with water to form KOHAq, with production of much heat. Von Schaffgotsch (A. 43, 17) says that  $K_2O \cdot Fe_2O_3$  is obtained, but not pure, by heating  $Fe_2O_3$  with  $K_2CO_3$ .

**POTASSIUM TETROXIDE**  $K_2O_4$  (*Potassium peroxide*). The formation of this compound by heating K in dry air or O was observed by Gay-Lussac & Thénard (*A. Ch.* 65, 325). The preparation and properties of the compound were examined by Vernon Harcourt (*C. J.* 14, 267). Prepared by heating K till it melts, in a hard glass flask filled with N, then sending in a slow stream of dry air, and continuing to heat in the air-stream until the metal is completely changed to a yellowish amorphous solid, and heating this for some time in dry O. It is also formed by throwing small pieces of K into molten  $KNO_3$  (Bolton, *C. N.* 52, 289). A mixture of  $K_2O$  with KOH.H<sub>2</sub>O is said to be formed by mixing equivalents of KOH and H<sub>2</sub>O<sub>2</sub> in Aq, and evaporating *in vacuo* (Schöne, A. 193, 241).  $K_2O_4$  is an amorphous powder, having the colour of  $PbCrO_4$ . It begins to soften at 280°, and melts at red heat to a black liquid, which crystallises in leaflets on cooling. At white heat gives off O and leaves  $K_2O$ . Deliquesces in moist air, giving off O. In water forms KOHAq and H<sub>2</sub>O<sub>2</sub>Aq, and evolves O. Heated in H produces KOH and H<sub>2</sub>O.  $K_2O_4$  oxidises P, S, C, &c., and many metals to their highest oxides. Reacts with CO, when heated, giving  $K_2CO_3$  and O. No action with  $N_2O$ ; with NO forms  $KNO_3$  and  $KNO_2$ , and gives off N oxides.

**OXIDES OF POTASSIUM OTHER THAN  $K_2O$  AND  $K_2O_4$ .** Harcourt (*loc.*) asserted the existence of  $K_2O_2$ , obtained by oxidation of K. Lupton (*C. J.* 1876, [2] 565) thought that the oxides  $K_2O$ ,  $K_2O_2$ , and  $K_2O_4$  are formed by the action of air on K at c. 65°; these oxides may be regarded, according to L., as  $3K_2O \cdot K_2O_2$ ,  $K_2O \cdot K_2O_2$ , and  $2K_2O \cdot K_2O_4$ , respectively. The substance described as a sub-oxide,  $K_2O$ , is said by L. to be a mixture of K and  $K_2O$ . Schöne (A. 193, 241) obtained  $K_2H_2O_8$ , probably  $K_2O_2 \cdot 2H_2O_2$ , by evaporating, *in vacuo*, at -10°, a mixture of 1 equiv. KOH and 2 equivs. H<sub>2</sub>O<sub>2</sub> in Aq.

**Potassium, phosphide of.** K and P combine when heated under rock-oil, or in N, forming a dark-yellow solid (Magnus, P. 17, 517; Vigier, A. 122, 831). A compound, or compounds, of K and P seems also to be formed when K is heated in  $PH_3$ , and also when K is heated in P in a stream of H (H. Rose, P. 12, 547). The compound prepared by Rose was a crystalline, reddish, lustrous solid; decomposed by water, giving  $KH_2PO_4$ Aq and  $PH_3$ , and burning, when heated in air, to K phosphate.

**Potassium, platinoeyanide of, and allied salts;** v. vol. II. pp. 844-5.

**Potassium, salts of.** Compounds formed by replacing H of acids by K. The chief salts of K, besides the halides and sulphides, are carbonates, chlorate and perchlorate, chromate and derivatives, iodate and periodates, nitrate and nitrite, phosphates and derivatives, silicates, Vol. IV,

sulphates and derivatives, sulphite, thiosulphate (v. CARBONATES, PHOSPHATES, &c.).

**Potassium, selenides of.** Berzelius (*Lehrbuch*, 5th ed. 2, 222) investigated the conditions of combination of K and Se, without isolating and analysing any definite compounds. Se and K combine when melted together; a steel-grey solid sublimes, which dissolves in water with formation of a red liquid that decomposes in air with separation of Se, and gives off H<sub>2</sub>Se with acids. Compounds of Se and K are also formed by reducing  $K_2SeO_4$  or  $K_2SeO_5$  by C or H at red heat (Wöhler & Dean, A. 97, 5; Rathke, A. 152, 211). Mixtures of selenate and selenides of K are formed by fusing KOH or  $K_2CO_3$  with Se. Boiling KOHAq dissolves Se, forming a brown liquid, from which a brown powder separates on evaporation, and which gives Se when heated with acids, or when diluted and allowed to stand in air.

Fabre (*C. R.* 102, 613) obtained  $K_2Se \cdot xH_2O$ ,  $x = 9, 14$ , and 19, by passing a rapid current of H<sub>2</sub>Se into KOHAq of different concentrations; these hydrates of potassium monoselenide are all very easily decomposed. Fabre (*C. R.* 102, 703) gives the following thermal data:  $[K_2Se] = 93,340$  from solid elements;  $[2KOHAq, H_2SeAq] = 7,520$ ;  $[2KOHAq, H_2Se] = 16,920$ ;  $[K_2Se, Aq] = 8,540$ .

**Potassium, selenocyanide of,** v. vol. II. p. 848.

**Potassium, selenostannate of,**  $K_2SnSe_3$  8aq. Yellow, unstable crystals; by saturating  $K_2SeAq$  with  $SnSe_2$ , and evaporating *in vacuo* (Ditte, *C. R.* 95, 641).

**Potassium, selenothioastannate of,**  $K_2SnSe_3$  8aq. Yellow, octahedral crystals; by boiling  $K_2SAq$  with Sn and Se, and evaporating *in vacuo*. Sol. water, with red colour. Both solid and solution in water very readily undergo decomposition, with separation of Se (Ditte, *loc.*).

**Potassium, silicide of.** By reducing  $SiO_2$  by K, Berzelius obtained a brown solid, which reacted with water to give H, KOHAq, and  $SiO_2$  (*Lehrbuch*, 5th ed. 2, 84).

**Potassium, silicofluoride of,**  $K_2SiF_6$ . Prepared by adding  $H_2SiF_6$ Aq to a fairly conc. solution of a K salt, washing, and drying. Small tesseral white crystals. Preis (*Listy Chem.* 13, 150; abstract in *C. J.* 58, 694) found hexagonal, and also regular, crystals of this salt, along with  $CaSO_4$ , in a basin wherein phosphoric acid had been prepared from phosphuric.  $K_2SiF_6$  is isodimorphous with the ammonium salt. S.G. 2.665 at 17.5° (Stolba, *J. pr.* 97, 503). Easily sol. hot water, very sl. sol. cold water. Melts at low red heat, giving off  $SiF_4$  and leaving KF (v. Bothe, *Hofman's Ber. über die Entwick. der Chem. Industrie*, 1, 318). Decomposed by conc.  $H_2SO_4$ , giving off  $SiF_4$  and HF. Decomposed by boiling (not cold) solutions of alkali hydroxides or carbonates, with separation of gelatinous silicic acid and formation of KF.

**Potassium, siliconitride of.** The white, infusible solid, obtained by heating  $SiO_2$  with KCN, is probably a compound of K, Si, and N (Balmann, *P. M.* October 1842).

**Potassium, sulphides of.** K and S combine when heated together, the K burning brilliantly. Five compounds of K and S are known:  $K_2S$ ,  $K_2S_2$ ,  $K_2S_3$ ,  $K_2S_4$ , and  $K_2S_5$ . They are all sol. water, the polysulphides also in alcohol.  $K_2SAq$  is colourless; solutions of the others are coloured

yellowish brown, the colour being deeper the greater the proportion of S. Solutions are decomposed by acids;  $K_2SAq$  with evolution of  $H_2S$ , the other solutions also with ppn. of S. Solutions decompose in air;  $K_2SAq$  to  $K_2S_2O_8Aq$  and  $KOHAq$ ,  $K_2S_2O_8Aq$  to  $K_2S_2O_7Aq$ , and the others to  $K_2S_2O_8Aq$  with separation of S. Solutions of the polysulphides react with  $K_2SO_4Aq$  to form  $K_2SAq$  and  $K_2S_2O_8Aq$ ; these solutions are reduced to  $K_2SAq$  by shaking with Hg. With  $EtI$  or  $EtBr$  they form  $Et_2S_2$ , which dissolves the S set free; these solutions dialyse unchanged (Spring a. Demarteau, *B.* [3] 1, 811).

**POTASSIUM MONOSULPHIDE  $K_2S$ .** Formed by reducing dry  $K_2SO_4$ ; by heating in H (Berzelius, *P.* 6, 438); by heating with C (Berthier, *A. Ch.* 22, 283; Bauer, *J. pr.* 75, 246; Wittstock, *P.* 55, 536). Not obtained free from polysulphides by these methods; if vessels of glass or porcelain are used the product contains  $SiO_2$ , as  $K_2S$  acts on silicates. The product of the foregoing reactions is a brown, crystalline, deliquescent solid; sol. in water, with production of much heat and formation of  $KSHAq$  and  $KOHAq$ ; Thomsen (*Th.* 3, 235) gives  $[K_2S, Aq] = 113, 300$ . Sabatier (*A. Ch.* [5] 23, 5) says that  $K_2S$  has never been obtained pure. An aqueous solution of  $K_2S$  is prepared by saturating  $KOHAq$  with  $H_2S$ , and adding an equal quantity of the same  $KOHAq$ . By evaporating this solution *in vacuo* at a low temperature, the pentahydrate  $K_2S \cdot 5H_2O$  is obtained in orthorhombic crystals, which lose  $H_2O$  by heating to  $150^\circ$ , out of air (Schöne, *P.* 181, 380; cf. Sabatier, *l.c.*).  $K_2SAq$  is colourless out of contact with air; it is very alkaline and caustic; in air it becomes yellow,  $H_2S$  is given off, and  $K_2CO_3Aq$  and  $K_2S_2O_8Aq$  are formed.  $K_2SAq$  dissolves S, forming polysulphides: it dissolves Fe or  $Fe_2O_3$ , forming a green liquid.

**POTASSIUM DISULPHIDE  $K_2S_2$ .** Formed by allowing an alcoholic solution of  $K_2S$  to stand in air till the surface is covered with a film of  $K_2S_2O_8$ , then pouring off, and evaporating *in vacuo* (Berzelius, *l.c.*). Also by heating 2 equivalents  $KHSO_4$  with 7 or more equivalents O (Geiger). Berzelius obtained  $K_2S_2$  by heating 4 equivalents  $K_2CO_3$  with rather less than 7 equivalents S. A yellowish red, deliquescent solid;  $K_2SAq$  is yellow; in air it oxidises to  $K_2S_2O_8Aq$  without separation of S; acids give off  $H_2S$  and cause ppn. of S.

**POTASSIUM TRISULPHIDE  $K_2S_3$ .** Formed by passing  $CS_2$  over  $K_2CO_3$  heated to redness (Berzelius, *l.c.*; cf. Schöne, *l.c.*). Also by heating 100 parts  $K_2CO_3$  with 58.22 parts S to dull redness, till  $CO_2$  ceases to be given off; the product contains some  $K_2SO_4$ . Also, with some S, by passing  $H_2S$  over strongly-heated  $K_2SO_4$ . By heating  $K_2S_2$  to over  $800^\circ$ . A yellowish-brown solid, black when molten; not decomposed at  $900^\circ$ , gives off S at white heat (B.). Easily sol. water and alcohol;  $K_2SAq$  in air gives  $K_2S_2O_8Aq$  with separation of S; decomposed by acids, S separating and  $H_2S$  being evolved.

**POTASSIUM TETRASULPHIDE  $K_2S_4$ .** Formed by passing  $CS_2$  over strongly-heated  $K_2SO_4$ , so long as  $CO_2$  is produced. Also by melting  $K_2CO_3$  with 1 to 2 parts S, heating till excess of S is removed, and then reducing  $K_2SO_4$ , formed by heating in  $H_2S$ . A red-brown, crystalline solid (B., *l.c.*; S., *l.c.*). Decomposed at  $800^\circ$ – $900^\circ$  to  $K_2S_2$  and S.

The dihydrate  $K_2S_4 \cdot 2H_2O$  is obtained by cooling  $K_2SAq$  with the proper quantity of S, and evaporating *in vacuo* (S., *l.c.*). Sabatier (*A. Ch.* [5] 22, 58) obtained the octahydrate,  $K_2S_4 \cdot 8H_2O$ , by adding 90 p.c. alcohol to  $K_2SAq$ , separating the brown oily liquid, and letting it crystallise.

**POTASSIUM PENTASULPHIDE  $K_2S_5$ .** Formed by heating any of the lower sulphides with S until the excess is removed; Schöne (*l.c.*) says temperature should not exceed  $600^\circ$  (v. B., *l.c.*). A solution of  $K_2S_5$ , containing also  $K_2S_2O_8$ , is formed by heating  $K_2CO_3Aq$  with S (Fordos a. Gélis, *C. R.* 23, 211); or by digesting a solution of a lower sulphide with S (B., *l.c.*). A red, fusible solid; decomposed by heating in steam, giving  $K_2SO_4$  and  $H_2S$  (Drechsel, *J. pr.* [2] 4, 20). Very sol. water, also in alcohol;  $K_2SAq$  slowly decomposes in air, giving  $K_2S_2O_8Aq$ ,  $K_2CO_3Aq$ , and S; acids evolve  $H_2S$  and separate S.

**Liver of sulphur.** This name is given to the brown solid obtained by heating S with  $K_2CO_3$  in a closed vessel; it contains various sulphides of K, along with  $K_2SO_4$ , and generally some  $K_2CO_3$ .

Potassium, sulphhydrate of; v. POTASSIUM HYDROSULPHIDE, p. 302.

Potassium, sulphocyanide of; v. vol. ii. pp. 351–2.

Potassium, telluride of. Probably  $K_2Te$ . By heating together K and Te in H; also by heating a mixture of 100 pts.  $H_2TeO_4$ , 20 pts. KOH, and 10 pts. C. A brittle, crystalline, copper-coloured solid. Easily sol. water; exposed to air Te separates from the solution.  $HClAq$  evolves  $H_2Te$  (Davy; v. also Berzelius, *Lehrbuch* (5th ed.) 2, 247).

Potassium, tellurofluoride of,  $KF \cdot TeF_4$ ; v. POTASSIUM FLUORIDE, p. 301.

Potassium, thio-arsenates and thio-arsenites of; v. vol. i. pp. 317, 316.

Potassium, thiocarbonate of; v. vol. i. p. 703. M. M. P. M.

**FRASEODYMIUM.** The constituent of didymium which yields green-coloured salts; v. DYMIUM, vol. ii. p. 383.

**PREHNITENE** v. c-DURENE.

**PREHNITIC ACID  $C_{10}H_8O_4$ , i.e.  $C_{10}H_7(CO_2H)_2$ , [1:2:3:4].** Mol. w. 254. [ $237^\circ$ – $250^\circ$ ]. Formed by heating either of the tetrahydrides of pyromellitic acid with  $H_2SO_4$  (Baeyer, *A.* 166, 325), and by the oxidation of c-durene and of c-tetra-ethyl-benzene (Töhl, *B.* 21, 907; Galle, *B.* 16, 1746; Jacobsen, *B.* 17, 2518). Crystallises from water in large prisms (containing 2aq) resembling the mineral prehnite. Converted by fusion into an anhydride  $C_{10}H_6O_4$  [ $239^\circ$ ]. May be reduced to a viscid hydride.— $KH_2A^{1+}aq$ .— $BaH_2A^{1+}3aq$ .— $BaH_2A^{1+}aq$ : needles.— $Pb_2A^{1+}$ : small needles, insol. water.

*Methyl ether*  $Me_2A^{1+}$ . [ $104^\circ$ – $108^\circ$ ].

**PREHNITOL** v. c-DURENOL.

**PREHNOMALIC ACID  $C_{10}H_8O_4$ , i.e.  $C_{10}H_7(OH)(CO_2H)_2$ .** *Oxy-prehnitic acid dihydride*. [ $210^\circ$ ]. A product of the action of  $H_2SO_4$  on the tetrahydrides of mellitic acid (Baeyer, *A.* 166, 325; B. 4, 275). Needles, readily converted by heat into an anhydride  $C_{10}H_6O_4$ , [ $210^\circ$ ]. By heating with  $H_2SO_4$ , or by treatment with Br, it is converted into prehnitic acid.— $Ag_2A^{1+}$ .

**PRIMULA CAMPHOR  $C_{15}H_{16}O_4$ , [49°].** (above  $200^\circ$ ). Contained in the root of *Primula*

*seris* (Mutschler, *A.* 185, 222). Six-sided plates, v. sl. sol. water, v. sol. alcohol and ether. Smells like anise. FeCl<sub>3</sub> colours its aqueous solution violet. Yields salicylic acid on oxidation.

**PRIMULINE BASE** C<sub>10</sub>H<sub>11</sub>N<sub>3</sub>S, *i.e.* -  
 $\text{C}_6\text{H}_5\text{Me} \langle \text{N} \rangle \text{C}_6\text{H}_4 \langle \text{S} \rangle \text{C}_6\text{H}_4 \langle \text{N} \rangle \text{C}_6\text{H}_4 \text{NH}_2$

Prepared by heating *p*-toluidine (2 mols.) with sulphur (4 or 5 atoms), H<sub>2</sub>S being evolved (Green, *C. J.* 55, 234). Yellowish powder, nearly insol. all solvents. Not decomposed at 400°. Its salts are decomposed by water. The Na salt of its sulphonic acid (primuline), is taken up by unmordanted cotton. KOH at 260° yields amidotolyl-mercaptan and *p*-amido-benzoic acid (Gattermann, *B.* 22, 425, 1066).

**Dehydrothioltoluidine** C<sub>10</sub>H<sub>11</sub>SN, *i.e.*

$\text{C}_6\text{H}_5\text{Me} \langle \text{N} \rangle \text{C}_6\text{H}_4 \text{NH}_2$ . [191°]. (434° at 766 mm.) (Pfitzinger a. Gattermann, *B.* 22, 1066). An intermediate body in the preparation of primuline. Formed, together with primuline base, by heating *p*-toluidine with S (Dahl & Co., *G. P.* 35790; Green, *C. J.* 55, 230). Got also by the action of HI and P upon primuline (Jacobsen, *B.* 22, 330). Yellowish iridescent needles (from isoamyl alcohol), v. sol. HOAc, sl. sol. hot alcohol, v. sl. sol. benzene, almost insol. boiling water. Its alcoholic solutions have violet-blue fluorescence. Ppd. by adding water to its solution in HClAq.

**Reactions.**—1. Yields *p*-toluidine on distillation with zinc-dust. —2. Yields primuline on heating with S. —3. Converted by diazotisation in

boiling alcoholic solution into C<sub>6</sub>H<sub>5</sub>Me <N>C<sub>6</sub>H<sub>4</sub> [123°]. —4. When diazotised and boiled with water it gives C<sub>10</sub>H<sub>11</sub>(OH)N<sub>3</sub>S [256°], which gives C<sub>10</sub>H<sub>11</sub>(OAc)N<sub>3</sub>S [132°]. —5. Fuming H<sub>2</sub>SO<sub>4</sub> (containing 70 p.c. SO<sub>3</sub>) forms, below 50°, a sulphonic acid C<sub>10</sub>H<sub>11</sub>(SO<sub>3</sub>H)SN<sub>3</sub>, which crystallises in yellow needles (containing aq.) or orange plates (containing 2 aq.), sl. sol. hot water, and forms NH<sub>4</sub>A<sup>aq</sup>, al. sol. hot water, CuA<sup>aq</sup>, 2 aq., a reddish-brown pp., and AgA<sup>aq</sup>, a white pp. —6. MeI yields C<sub>10</sub>H<sub>11</sub>(NMe)<sub>3</sub>NS [197°] (434°), and C<sub>10</sub>H<sub>11</sub>(NMe)<sub>3</sub>I NS, a bright-yellow powder, v. sol. water. MeOH and HCl at 150°–200° give C<sub>10</sub>H<sub>11</sub>(NMe,Cl)NS, a yellow powder which forms (C<sub>10</sub>H<sub>11</sub>NS.NMe,Cl)PtCl<sub>3</sub> [234°].

**Acetyl derivative** C<sub>10</sub>H<sub>11</sub>AcN<sub>3</sub>S. [227°]. White plates or prisms, sl. sol. HOAc.

**PROPACONIC ACID** v. *Lactone of Oxobutylmaleic acid*.

**PROPANE** C<sub>3</sub>H<sub>8</sub>, *i.e.* CH<sub>3</sub>CH<sub>2</sub>CH<sub>3</sub>. Mol. w. 44. (–17°). S. (alcohol) 6. H.F.p. 35, 110. H.F.v. 33, 370 (Thomsen, *Th.* 4, 52). Occurs in the gases given off from the petroleum springs of the United States (Ronalds, *C. J.* 18, 54; Lefevre, *Z.* [2] 5, 185). Formed by the action of HI on propyl iodide, allyl iodide, isopropyl iodide, acetone, and glycerin (Berthelot, *Bl.* 7, 60; 9, 13, 184). Prepared by heating *n*-propyl iodide (9.6 pts.) with AlCl<sub>3</sub> (2.5 pts.) at 140° (Köhnlein, *B.* 16, 560), or by heating isopropyl iodide with zinc and HClAq (Sehormlemmer, *A.* 150, 209). Gas. On compression with water at a low temperature it yields a hydrate, dissociating at 8.5° (Villard, *C. R.* 111, 302).

**References.**—Di-bromo-, Bromo-iodo-, Bromo-

nitro-, Chloro-, Chloro-iodo-, Di-chloro-nitro-, Di-iodo, and Nitro-Propane.

**PROPANE CARBOXYLIC ACID** v. **BUTYRIC ACID**.

**Propane dicarboxylic acid** v. **GLUTARIC, PYROTARTARIC, and ETHYL-MALONIC ACIDS**.

**Propane tricarboxylic acid** C<sub>3</sub>H<sub>4</sub>O<sub>6</sub>, *i.e.* CH<sub>2</sub>.CH(CO<sub>2</sub>H).CH(CO<sub>2</sub>H)<sub>2</sub> (Bischoff, *B.* 18, 2164; 14, 614; 15, 1107; 17, 2783; 22, 8180; *A.* 214, 53). [146°]. Formed by saponifying the ether with dilute alcoholic potash. Crystalline mass, v. e. sol. water, alcohol, and ether. Splits up when heated alone, or with dilute HClAq, into CO<sub>2</sub> and pyrotartaric acid. Bromine forms bromopyrotartaric and bromocrotonic acids.—Ba.A<sup>aq</sup>; bulky pp.

**Methyl-di-ethyl ether** MeEt.A<sup>aq</sup>. (268°). S.G.  $\frac{4}{3}$  1.078. Formed from methyl  $\alpha$ -chloropropionate and sodium malonic ether.

**Ethyl ether** Et.A<sup>aq</sup>. (270.3° cor.). S.G.  $\frac{2}{3}$  1.0698.  $\mu_D = 1.4288$  at 20°. Formed from sodium malonic ether and  $\alpha$ -bromo-propionic ether. Oil, miscible with alcohol and ether. NaOEt yields C<sub>3</sub>H<sub>7</sub>Na(CO<sub>2</sub>Na)(CO<sub>2</sub>Et)<sub>2</sub>.

**Propane tricarboxylic acid**

CH<sub>2</sub>.C(CO<sub>2</sub>H).CH<sub>2</sub>.CO<sub>2</sub>H.

**Methyl ether** Me.A<sup>aq</sup>. Oil (Barthe).

**Ethyl ether** Et.A<sup>aq</sup>. (273.6° cor.). S.G.  $\frac{2}{3}$  1.077.  $\mu_D = 1.4311$  at 20°. Formed from sodium methyl-malonic ether and chloro-acetic ether, and also from sodium ethane tricarboxylic ether and MeI or MeCl (Bischoff a. Von Kuhlberg, *B.* 23, 635). Yields on saponification pyrotartaric and a little succinic acid.

**Methyl ether of the mono-nitrile** CH<sub>2</sub>.C(CN)(CO<sub>2</sub>Me).CH<sub>2</sub>.CO<sub>2</sub>Me. Formed from methyl cyanosuccinate, MeOH, and MeI at 70° (Barthe, *Bl.* [3] 1, 303; *C. R.* 108, 297; 112, 1013). Oil. The corresponding CH<sub>2</sub>.C(CN)(CO<sub>2</sub>Et).CH<sub>2</sub>.CO<sub>2</sub>Et is also an oil (185° at 35 mm.).

**Propane tricarboxylic acid**

CO<sub>2</sub>H.CH<sub>2</sub>.CH<sub>2</sub>.CH(CO<sub>2</sub>H).

**Ethyl ether** Et.A<sup>aq</sup>. (161° at 13 mm.). S.G.  $\frac{2}{3}$  1.0808. Formed from sodium malonic ether and  $\beta$ -bromo-propionic ether (Emery, *B.* 24, 282). The free acid splits up into CO<sub>2</sub> and glutaric acid on boiling with HClAq.

**Isomeride** v. **TRICARBALLYLIC ACID**.

**Propane tetracarboxylic acid**

CO<sub>2</sub>H.CH<sub>2</sub>.CH(CO<sub>2</sub>H).CH(CO<sub>2</sub>H).

**Ethyl ether** Et.A<sup>aq</sup>. (204° at 18 mm.). S.G.  $\frac{2}{3}$  1.1184. Formed from sodium malonic ether and chloro-succinic ether (Emery, *B.* 23, 8759). Oil, v. sol. alcohol and ether. The free acid splits up into CO<sub>2</sub> and tricarballic acid.

**Propane tetracarboxylic acid**

(CO<sub>2</sub>H).CH.CH<sub>2</sub>.CH(CO<sub>2</sub>H)<sub>2</sub>. **Dicarboxy-glutaric acid**. [170°]. An acid formed by the action of sodium amalgam on dicarboxyglutaconic ether C<sub>3</sub>H<sub>2</sub>Et<sub>2</sub>O<sub>4</sub> in alkaline solution (Conrad a. Guthzeit, *A.* 222, 257). One of the products of the action of chloro-di-methyl oxide on sodium malonic ether (Kleber, *A.* 246, 106). Got also by boiling its ether with dilute alcoholic potash (Guthzeit a. Dressel, *B.* 21, 2234; 22, 1423; *A.* 256, 174). Crystalline powder (from ether), v. e. sol. water. At 180° it splits up into CO<sub>2</sub> and glutaric acid [98°].—Ba<sub>2</sub>A<sup>aq</sup> 2 aq.—Ca<sub>2</sub>A<sup>aq</sup> 2 aq.—Pb<sub>2</sub>A<sup>aq</sup> 2 aq.

**Ethyl ether** Et.A<sup>aq</sup>. (235° at 80 mm.).

**S.G.** 1-116. Formed from sodium malonic ether by treatment with  $\text{CH}_3\text{Cl}$ , or  $\text{CH}_3\text{I}$ , and got also by reducing dicarboxy-glutaconic ether with zinc-dust and  $\text{HOAc}$  (W. H. Perkin, jun., *C. J.* 59, 993). Oil, with very bitter taste.  $\text{NaOEt}$  forms a di-sodium derivative, which reacts with  $\text{EtI}$  forming oily  $\text{C}_7\text{H}_{14}\text{O}_8$  (c.  $248^\circ$  *in vacuo*).

**Propyl-tri-ethyl ether**  $\text{Et}_3\text{Pr}^{\text{A}}$ . ( $195^\circ$ – $202^\circ$  at 15 mm.). Formed from propyl triethyl dicarboxy-glutaconate, zinc-dust, and  $\text{HOAc}$ . Colourless oil.

**Propane tetracarboxylic acid**  $\text{OO}_2\text{H}_2\text{CH}_2\text{C}(\text{CO}_2\text{H})_2\text{CH}_2\text{CO}_2\text{H}$ . [ $151^\circ$ ]. Got by saponifying its ether with alcoholic potash. Prisms (from water), v. sol. water, alcohol, and ether. At  $170^\circ$  it splits up into  $\text{CO}_2$  and tricarballic acid. —  $\text{K}_2\text{HA}'2\text{aq}$  (at  $100^\circ$ ). —  $\text{Zn}_2\text{A}'3\text{aq}$  (dried at  $100^\circ$ ). —  $\text{Pb}_2\text{A}'\text{aq}$ . —  $\text{Ag}_2\text{A}'$ : insoluble pp.

**Ethyl ether**  $\text{Et}_2\text{A}'$ . ( $295^\circ$  uncor.). **S.G.** 1-102. Formed from malonic ether, alcoholic  $\text{NaOEt}$ , and chloro-acetic ether, followed by a second dose of  $\text{NaOEt}$  and chloro-acetic ether (Bischoff, *B.* 13, 2163; *A.* 214, 61). Oil.

**Ethyl ether of the mono-nitrile**  $\text{CO}_2\text{Et}.\text{CH}_2.\text{C}(\text{CN})(\text{CO}_2\text{Et}).\text{CH}_2.\text{CO}_2\text{Et}$ . [ $41^\circ$ ]. ( $200^\circ$ – $215^\circ$  at 10 mm.). Formed from sodium cyano-succinic ether and chloro-acetic ether (Haller a. Barthe, *C. R.* 106, 1413). White crystals, sol. alcohol and ether.

**Methyl ether of the mono-nitrile**  $\text{CO}_2\text{Me}.\text{CH}_2.\text{C}(\text{CN})(\text{CO}_2\text{Me}).\text{CH}_2.\text{CO}_2\text{Me}$ . [ $47^\circ$ ]. Prepared in like manner (Barthe, *C. R.* 111, 844). Prisms, insol. water and alkalis.

**Propane pentacarboxylic acid**  $\text{CH}(\text{CO}_2\text{H})_2.\text{C}(\text{CO}_2\text{H})_2.\text{CH}_2.\text{CO}_2\text{H}$ . [ $151^\circ$ ]. Got by saponifying its ether. Spherical aggregates (from ether). —  $\text{K}_2\text{A}'4\text{aq}$ . —  $\text{Ba}_2\text{A}'4\text{aq}$ : crystalline pp.

**Ethyl ether**  $\text{Et}_2\text{A}'$ . ( $275^\circ$ – $280^\circ$  at 188 mm.). **S.G.**  $\frac{1}{2}$  1-121 (Bischoff, *B.* 15, 1107; 21, 2113). Formed from sodium-malonic ether and  $\text{CCl}(\text{CO}_2\text{Et})_2.\text{CH}_2.\text{CO}_2\text{Et}$ . Formed also from sodium ethane tricarboxylic ether and chloro-acetic ether. Oil.

**Reference.**—OXYPROPANE TRICARBOXYLIC ACID.

#### PROPANE PHOSPHONIC ACID

$\text{C}_3\text{H}_7\text{PO}(\text{OH})_2$ . [ $60^\circ$ – $70^\circ$ ]. Prepared by oxidation of propyl-phosphine with fuming  $\text{HNO}_3$  (Hofmann, *B.* 6, 304). Wax-like mass, sol. water.

#### PROPANE SULPHONIC ACID

$\text{CH}_3.\text{CH}_2.\text{CH}_2.\text{SO}_3\text{H}$ . Formed by oxidation of propyl mercaptan with nitric acid (**S.G.** 1-3) (Spring a. Winssinger, *Bl.* [2] 48, 110).  $\text{ICl}_3$  at  $160^\circ$  forms chloro-propane sulphonic acid,  $\text{CCl}_3$ , and  $\text{C}_3\text{Cl}_3$ .

**Propane sulphonic acid**  $(\text{CH}_3)_3\text{CH}.\text{SO}_3\text{H}$ . [below  $100^\circ$ ]. Formed by oxidising isopropyl mercaptan with  $\text{HNO}_3$ . Obtained also from acetone by successive treatment with  $\text{P}_2\text{S}_5$  and  $\text{HNO}_3$  (Claus, *B.* 5, 660; 8, 533; Spring, *Bl.* [2] 40, 66). Crystalline. Its salts are v. e. sol. water.

#### Propane disulphonic acid

$\text{CH}_3(\text{SO}_3\text{H}).\text{CH}_2.\text{CH}_2(\text{SO}_3\text{H})$ . Formed by boiling trimethylene bromide with a saturated solution of ammonium sulphite (Monari, *B.* 18, 1345). Deliquescent needles, v. sol. water and alcohol. —  $\text{Na}_2\text{A}''4\text{aq}$ . —  $\text{BaA}''2\text{aq}$ : very soluble needles.

#### Propane disulphonic acid

$\text{CH}_3.\text{CH}(\text{SO}_3\text{H}).\text{CH}_2(\text{SO}_3\text{H})$ . Formed in like manner from propylene bromide (**M.**). —  $\text{Na}_2\text{A}''\text{aq}$ . —  $\text{BaA}''$ : sparingly soluble crystals.

**Propane disulphonic acid**  $\text{C}_3\text{H}_7(\text{SO}_3\text{H})_2$ . Got from butyramide and fuming  $\text{H}_2\text{SO}_4$  (Buckton a. Hofmann, *A.* 100, 153), and also by heating butyric acid with  $\text{ClSO}_3\text{H}$  at  $140^\circ$  (Baumstark, *A.* 140, 83). —  $\text{BaA}''$ . —  $\text{PbA}''$ : crystalline.

#### Propane trisulphonic acid

$\text{CH}_3(\text{SO}_3\text{H}).\text{CH}(\text{SO}_3\text{H}).\text{CH}_2(\text{SO}_3\text{H})$ . Got by boiling s-tri-chloro-propane with aqueous  $\text{K}_2\text{SO}_3$  (Schäuffelin, *A.* 143, 117). —  $\text{BaA}'''$ : crystalline powder, sl. sol. water.

**References.**—CHLORO- and OXY-PROPANE SULPHONIC ACID.

#### DIPROPARGYL $\text{C}_6\text{H}_8$ i.e.

$\text{CH}_3\text{C}.\text{CH}_2.\text{CH}_2.\text{C}.\text{CH}_3$ . **Hexunene**. ( $85^\circ$ ). **S.G.** 1-81. **H.F.p.** —  $96,040$ . **H.F.v.** —  $97,200$  (Thomson, *Th.*). Formed by distilling diallyl tetrabromide with solid  $\text{KOH}$ , and boiling the resulting dibromo-diallyl with alcoholic potash (Henry, *B.* 6, 956; 7, 21; 14, 399; 17, 1132). Limpid, highly refractive oil, v. sol. ether. Burns with smoky flame. Combines with explosive violence with bromine, forming  $\text{C}_6\text{H}_8\text{Br}_4$ , a thick liquid **S.G.** 1-2-464, from which, by further action of  $\text{Br}$ , crystalline  $\text{C}_6\text{H}_8\text{Br}_4$  [ $141^\circ$ ] can be obtained. Iodine in  $\text{KI}$  forms dipropargyl tetraiodide  $\text{C}_6\text{H}_8\text{I}_4$  [ $113^\circ$ ] crystallising from  $\text{CS}_2$  in prisms. Dipropargyl gives with ammoniacal cuprous chloride a yellow pp.  $\text{Cu}_2\text{C}_6\text{H}_8$  2aq, which explodes at about  $100^\circ$ . Aqueous  $\text{AgNO}_3$  ppts.  $\text{Ag}_2\text{C}_6\text{H}_8$  2aq, which explodes below  $100^\circ$ . Dipropargyl is very easily polymerised, forming a resin.

#### PROPARGYL ALCOHOL $\text{C}_3\text{H}_3\text{O}$ i.e.

$\text{CH}_3\text{C}.\text{CH}_2.\text{OH}$ . **Mol. w.** 56. ( $115^\circ$ ). **V.D.** 1-88 (calc. 1-93). **S.G.**  $\frac{2}{3}$  0-9715.  $\mu_D^{20}$  — 1-437. **R.D.** —  $24.01$  (Brühl). **H.F.p.** —  $3,500$ . **H.F.v.** —  $4,370$  (Thomson, *Th.*). Formed by boiling bromo-allyl alcohol with  $\text{KOH}$ aq (Henry, *B.* 5, 274, 449, 569; 6, 728; 7, 20, 761). Formed also from propargylamine oxalate,  $\text{NaNO}_2$ , and  $\text{HCl}$  (Paal a. Hempel, *B.* 24, 3039). Colourless liquid of peculiar odour, sol. water.

**Reactions.**—1. Ammoniacal  $\text{Cu}_2\text{Cl}_2$  ppts. canary-yellow  $\text{Cu}_2(\text{C}_3\text{H}_3\text{O})_2$ , which explodes when heated, and is decomposed by dilute acids with reproduction of propargyl alcohol.—2. Ammoniacal  $\text{AgNO}_3$  ppts. white  $\text{AgC}_3\text{H}_3\text{O}$ .—3. Anhydrous  $\text{BaO}$  forms  $\text{Ba}(\text{C}_3\text{H}_3\text{O})_2$ , crystallising in small plates.—4. On heating with solid  $\text{KOH}$  it yields formic acid and acetylene.—5.  $\text{HBr}$  forms bromo-allyl alcohol.—6.  $\text{HNO}_3$  yields  $\text{CO}_2$  and oxalic acid.

**Acetyl derivative**  $\text{C}_3\text{H}_3\text{OAc}$ . ( $125^\circ$ ). **S.G.**  $\frac{2}{3}$  1-0052.  $\mu_D^{20}$  — 1-427. **R.D.** —  $39.71$  (Brühl). Got from the alcohol and  $\text{AcCl}$ .

**Methyl ether**  $\text{C}_3\text{H}_3\text{OMe}$ . ( $62^\circ$ ). **S.G.** 1-83. **H.F.p.** —  $10,910$ . **H.F.v.** —  $12,360$  (Thomson, *Th.*). Formed by boiling s-tri-bromo-propane with  $\text{KOH}$  dissolved in  $\text{MeOH}$  (Liebermann, *A.* 135, 287) and by boiling the dibromide of methyl allyl oxide with alcoholic potash (Henry). Ammoniacal  $\text{AgNO}_3$  ppts. lemon-yellow  $\text{C}_3\text{H}_3\text{AgOMe}$ , whence  $\text{I}$  in  $\text{KI}$  forms oily  $\text{C}_3\text{H}_3\text{LOMe}$  [ $12^\circ$ ].

**Ethyl ether**  $\text{C}_3\text{H}_3\text{OEt}$ . ( $81^\circ$ – $85^\circ$ ). **S.G.**  $\frac{2}{3}$  0-8326.  $\mu_D^{20}$  — 1-4096. **R.D.** —  $39.5$  (Brühl). This body is formed by the action of alcoholic potash on  $\text{CH}_3\text{Br}.\text{CHBr}.\text{CH}_2\text{Br}$ , on  $\text{CH}_3.\text{CBr}_2.\text{CH}_2\text{Br}$ ,

on dichloropropylene, or on ethyl bromo-allyl oxide (Liebemann, *A.* 135, 278; 158, 230; Henry, *B.* 5, 274; Baeyer, *A.* 138, 196). Mobile liquid, with penetrating odour, v. sl. sol. water, miscible with alcohol. Combines with Br, forming  $C_3H_5Br_2OEt$ . Boiling very dilute (1 p.c.)  $H_2SO_4$  splits it up into alcohol and propargyl alcohol. Sodium forms  $C_3H_5NaOEt$ . Alcoholic silver nitrate forms crystalline  $(C_3H_5AgOEt)_2AgNO_3$  converted by ammonia into amorphous  $C_3H_5AgOEt$ , whence 1 in KI forms crystalline  $C_3H_5IOEt$  and oily  $C_3H_5IOEt$ . An ammoniacal solution of AgCl added to an alcoholic solution of  $C_3H_5OEt$  ppts. white  $(C_3H_5AgOEt)_2AgCl$ . Ammoniacal  $CaCl_2$  gives yellow amorphous  $C_3H_5CaOEt$ .

*Isoamyl ether*  $C_3H_5OC_5H_{11}$ . (140°-145°).

**PROPARGYLAMINE**  $C_3H_5NH_2$ . Formed by the action of NaOEt on bromo-allyl-amine and on di-bromo-propyl-amine (Paal a. Hermann, *B.* 22, 3080). The free base has not been isolated.  $-B'H_2C_2O_4$ . [143°]. Large tables (from water), sl. sol. alcohol. Gives a white pp. with ammoniacal  $AgNO_3$ .  $-B'C_3H_5(NO_3)_2OH$ . [189°]. Large red plates or tables.  $-B'HI$ .  $-B'HI$ . [130°-171°].  $-B'HI$ . [205°]. White plates, v. e. sol. water.

**PROPARGYL-ISOAMYL-AMINE**  $C_8H_{13}N$  i.e.  $C_3H_5NH(C_5H_{11})$ . Formed from di-bromo-isoamyl-amine and NaOEt (Paal a. Hermann, *B.* 22, 3084). Liquid.  $-B'H_2C_2O_4$  aq. [204°]. White needles (from water).  $-B'HI$ . [186°]. Pearly plates.

**PROPARGYL BROMIDE**  $CH_3CCH_2Br$ . (89°). S.G.  $\frac{1}{4}$  1.59. Formed from propargyl alcohol and PBr<sub>3</sub> (Henry, *B.* 6, 728). Liquid.

**Propargyl tribromide v. Tri-bromo-propylene**.

**PROPARGYL-ISOBUTYL-AMINE**  $C_8H_{13}N$  i.e.  $CH_3CCH_2NH(C_4H_9)$ . (135°). Formed from di-bromo-propyl-isobutyl-amine and NaOEt (Paal a. Heupel, *B.* 24, 3045). Liquid, miscible with water.  $-B'HI$ . [148°].  $-B'_2H_4PtCl_6$ . [172°].  $-B'H_2C_2O_4$ . [210°]. Needles and plates, m. sol. cold water.

**PROPARGYL CHLORIDE**  $C_3H_5Cl$ . (65°). S.G.  $\frac{1}{4}$  1.045. Formed from propargyl alcohol and PCl<sub>5</sub> (Henry, *B.* 8, 398). Mobile oil.

**PROPARGYLIC ACID** is Propiolic acid.

**PROPARGYL IODIDE**  $CH_3CCH_2I$ . (c. 115°). S.G.  $\frac{2}{4}$  2.018. Formed from propargyl bromide and NaI in alcohol (Henry, *B.* 17, 1132). Yellowish liquid. Iodine forms  $CHI:ClCH_2I$ . [41°].

**PROPARGYL-PROPYL-AMINE**  $C_6H_{11}N$  i.e.  $C_3H_5NH(C_3H_7)$ . The salt  $B'HI$  [180°] is got from propyl bromide and propargylamine (Paal a. Hermann, *B.* 22, 3084).

**PROPARGYL SULPHOCYANIDE**  $C_3H_5SCN$ . Formed from propargyl bromide and potassium sulphocyanide (Henry, *B.* 6, 729). Oil, smelling like mustard. Decomposed by heat.

**PROPARGYL-DI-THIO-CARBAMIC ACID**  $CH_3CCH_2NHCS_2H$ . (115°). Formed by boiling propargylamine with  $CS_2$  and alcohol (Paal a. Heupel, *B.* 24, 3041). Needles (from dilute alcohol) or plates (from benzene-ligroin).

**PROPENYL-o-AMIDO-PHENOL** **CARB- OXYLIC ETHER**  $C_6H_4<\overset{O}{N}>CMe.CH_2.CO_2Et$ . [108°]. Formed by heating a mixture of o-amido-phenol and acetoacetic ether (Hantzsch, *B.* 16,

1948). Flat prisms, readily resolved into the parent substances by dilute acids, alkalis, or even boiling water.

**PROPENYL-o-AMIDO-PHENYL MERCAP-**

**TAN**  $C_6H_4NS$  i.e.  $C_6H_4<\overset{N}{S}>CEt$ . (252°).

Formed by heating o-amido-phenyl mercaptan with propionyl chloride at 160° (Hofmann, *B.* 13, 21). Heavy oil.  $-B'_2H_4PtCl_6$ : large prisms.

**PROPENYLAMINE**  $CH_3CH=CH.NH_2$ .

Formed by the action of baryta on  $\beta$ -bromo-propylamine (Hirsch, *B.* 23, 968). Does not decolourise bromine water.  $-B'_2H_4I_2BiI_3$ : six-sided plates.

**PROPENYL-BENZENE SULPHONIC ACID**

$CH_2=CH.C_6H_4.SO_3H$ . The salts of this acid are formed by heating the dry salts of the acid  $CH_2=CH.C_6H_4.SO_3H$  (R. Meyer, *A.* 219, 802).

*Amide*  $C_6H_4SO_2NH_2$ . [152°].

**o-PROPENYL-BENZOIC ACID**

$CH_2=CH.C_6H_4.CO_2H$ . [61°]. Formed from dimethyl-phthalide and KCy at 260° (Wislicenus, *A.* 218, 64). Needles (from water).

**p-Propenyl-benzoic acid**

$CH_2=CH.C_6H_4.CO_2H$ . [161°]. Formed by heating  $(CH_3)_2C(OH).C_6H_4.CO_2H$  with dilute HCl on a water bath (R. Meyer a. J. Kosicki, *B.* 11, 1791; *A.* 219, 270). White satiny plates (from 1 pt. alcohol and 1 pt. water) or slender needles (from water). Sl. sol. hot water, v. e. sol. alcohol and ether. Sodium amalgam reduces it to cuminic acid.

Salts.  $-NH_4A'$ .  $-BaA'$ , aq.  $-CuA'$ , 7aq.  $-AgA'$ : amorphous pp.

*Methyl ether*.  $-MeA'$  [53°]. (254° cor.). V.D. 6.09. Insol. water.

**Isopropenyl-benzoic acid**  $C_7H_7.CO_2H$  [255°-260°]. By boiling oxy-propyl-benzoic acid  $(CH_3)_2C(OH).C_6H_4.CO_2H$  with fuming HCl (R. Meyer, *B.* 12, 1076; *A.* 219, 281). Minute needles grouped in stars (from alcohol). Insol. water. Does not decolourise bromine, and is not reduced by sodium amalgam, but is converted by HI into cuminic acid. Hence it would appear to be a polymeride of propenyl-benzoic acid, not containing a C:C group.

Salts.  $-NH_4A'$  aq. Sl. sol. water.  $-BaA'$ , aq.  $-CaA'$ , 1½aq.  $-CuA'$ .  $-AgA'$ : pp., insol. water.

*Methyl ether*  $MeA'$ . [83°]. Decomposed by heat.

**References.**—AMIDO-, NITRO-, and OXY- PROPENYL-BENZOIC ACID.

**PROPENYL BROMIDE v. BROMO-PROPYLENE.**

**PROPENYL CARBINOL v. BUTENYL ALCOHOL.**

**PROPENYL-TRICARBOXYLIC ACID v. PROPANETRICARBOXYLIC ACID.**

**PROPENYL CHLORIDE v. CHLORO-PROPYLENE.**

**PROPENYL-PHENOL.** *Methyl derivative v. ANETHOL.*

**PROPENYL-ISOPROPYL BENZENE**  $C_{11}H_{14}$  i.e.  $Pr.C_3H_7.CH=CHMe$ . (230°). S.G.  $\frac{1}{4}$  0.890. Got by boiling  $Pr.C_3H_7.CH_2.CBrMe.CO_2H$  with  $Na_2CO_3$  aq (Perkin, *C.* J. 1877, ii. 660). *Di-bromide*  $C_{11}H_{12}Br_2$ . [59°].

**PROPENYL-SALICYLIC ACID v. OXY-PROPENYL-BENZOIC ACID.**

**PROPEPTONE v. PROTEIN.**

**PROPHETIN**  $C_{20}H_{26}O_2$ . A bitter resin got from the fruit of *Cucumis prophetarum*, split up

by boiling dilute  $\text{HCl}$  into glucose and prophetin  $\text{C}_{12}\text{H}_{18}\text{O}_5$  (Walz, *J.* 1859, 566).

**PROPINENE** v. ALLYLENE.

**PROPINENE DIPHTHALIDE**  $\text{C}_{11}\text{H}_{12}\text{O}_4$ , i.e.

heating phthalic anhydride (3 pts.) with pyrotartaric acid (3 pts.) and sodium acetate (1 pt.) at  $240^\circ$ – $290^\circ$  (Roser, *B.* 17, 2776). Fine yellow needles, not melted at  $280^\circ$ .

**PROPIO-GUANAMINE**  $\text{C}_7\text{H}_{12}\text{N}_4$ , i.e.

idine propionate at  $230^\circ$  for an hour (Haaf, *J. pr.* [2] 43, 78). Granules (from  $\text{NaOH}$  aq) or dimetric prisms (from water).

**PROPIO-HOMO-FERULIC ACID** v. Di-oxypentyl-crotonic acid.

**PROPIOLIC ACID**  $\text{C}_3\text{H}_4\text{O}_2$ , i.e.  $\text{CH}_3\text{C} \cdot \text{CO}_2\text{H}$ .

*Propargylic acid.* ( $8^\circ$ ). (c.  $14^\circ$ ). Formed by boiling the acid K salt of acetylene dicarboxylic acid with water (Bandrowski, *B.* 13, 2340). Liquid, solidifying at about  $4^\circ$ . Smells like acetic acid. Turns brown in air. Sol. water, alcohol, and ether. Reduces  $\text{HgCl}_2$ ,  $\text{AgNO}_3$ , and  $\text{PtCl}_4$ .

*Reactions.*—1. Ammoniacal  $\text{AgNO}_3$  gives a white crystalline explosive pp.—2. Ammoniacal  $\text{Cu}_2\text{Cl}_2$  gives a green amorphous explosive pp., turning brown.—3. Sodium-amalgam reduces it to propionic acid.—4. Combines with  $\text{HCl}$ , forming  $\beta$ -chloro-acrylic acid.  $\text{HBr}$  and  $\text{HI}$  act in like manner.—5. Br forms di-bromo-acrylic acid ( $85^\circ$ ).—6. I forms  $\text{CHI} \cdot \text{Cl} \cdot \text{CO}_2\text{H}$  [ $104^\circ$ ] (Bruck, *B.* 24, 4120).

*Salt.*— $\text{KA}'$  aq. Transparent prisms, v. sol. water, deflagrating at  $105^\circ$ .

*Ethyl ether EtA'*. ( $119^\circ$ ). V.D. 3.47. Liquid, smelling like horse-radish. Oxidised by alkaline  $\text{K}_2\text{FeCy}$  to diacetylene dicarboxylic acid (Baeyer, *B.* 18, 677, 2269).

*Reference.*—Bromo- and Iodo-PROPIOLIC ACID.

**PROPIONAMIDE** v. Amide of PROPIONIC ACID.

**PROPIONAMIDINE**  $\text{C}_3\text{H}_7\text{N}$ , i.e.

$\text{OEt}(\text{NH})\text{NH}_2$ . The hydrochloride is formed by leading  $\text{HCl}$  into a solution of propionitrile in isobutyl alcohol, and heating the product with alcoholic  $\text{NH}_3$  (Pinner & Klein, *B.* 11, 1484; 17, 176; 18, 2845). Very unstable oil, sl. sol. ether. On heating with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  it yields a base  $\text{C}_3\text{H}_7\text{N}$ , [ $204^\circ$ ].— $\text{B}'\text{HCl}$ . [ $129^\circ$ ]. Needles, insol. ether.— $\text{B} \cdot \text{H}_2\text{PtCl}_6$ . [ $200^\circ$ ].— $\text{B}'\text{HNO}_3$ . [ $116^\circ$ ]. Crystals (from alcohol), v. sol. water (C. Lossen, *A.* 265, 167).

*Reference.*—Oxy-PROPIONAMIDINE.

**PROPIONE** v. Di-ethyl ketone.

**PROPIONIC ACID**  $\text{C}_3\text{H}_4\text{O}_2$ , i.e.  $\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$ .

*Metacetic acid.* Mol. w. 74. [ $-23^\circ$ ] (Petersson, *J. pr.* [2] 24, 295). ( $140\text{--}7^\circ$  cor.) (Zander). S.G.  $\frac{4}{4}$  9946 (B.);  $\frac{15}{15}$  9983;  $\frac{25}{25}$  9896 (Perkin). M.M.  $3.463$  at  $20^\circ$ .  $\mu_D = 1.391$ .  $R_D = 28.01$  (Brühl). S.V.  $85.3$ . C.E. ( $0^\circ$ – $10^\circ$ ) 00106. H.F.p. 109.450. H.F.v. 107.710 (Thomsen, *Th.*). S.H. 440 at  $0^\circ$  (B. Schiff, *A.* 234, 300). Critical temperature  $340^\circ$  (Pawlewski, *B.* 16, 2634). Occurs in the fruit of *Ginkgo biloba* (Béchamp, *A.* 180, 864), in suint (Buisine, *Bl.* [2] 43, 639), and in wood vinegar (Anderson, *C. N.* 14, 267; Barré, *Z.* [3] 5, 445).

*Formation.*—1. By oxidation of metacetone with chromic acid (Gottlieb, *A.* 52, 121).—2. By potash-fusion from sugar, starch, mannite, and angelic acid (G.).—3. By reduction of acrylic acid (Linnemann, *A.* 125, 317), of lactic acid (Lautemann, *A.* 118, 217), and of pyruvic acid (Wislicenus, *A.* 126, 229).—4. By heating potassium oxalate with dry  $\text{NaOEt}$  (Van't Hoff, *B.* 6, 1107).—5. By heating  $\text{NaOEt}$  with  $\text{CO}$  at  $180^\circ$  (Fröhlich, *A.* 202, 290; cf. Hagemann, *B.* 4, 877).—6. From  $\text{ZnEt}_2$ , sodium, and  $\text{CO}_2$  (Wanklyn, *A.* 107, 125).—7. Together with di-ethyl ketone, by heating  $\text{ZnEt}_2$  with  $\text{CO}$ , at  $160^\circ$  (Schmitt, *J. pr.* [2] 42, 568).—8. By the action of sunlight on a solution of succinic acid containing a uranium salt (Seekamp, *A.* 133, 253). 9. By heating barium succinate with  $\text{NaOMe}$  for 8 hours at  $300^\circ$  (Mai, *B.* 22, 2133).—10. Among the products of destructive distillation of colophony (Renard, *C. R.* 103, 157).

*Preparation.*—1. By oxidation of *n*-propyl alcohol (Pierre & Puchot, *A. Ch.* [4] 28, 75).—2. By saponification of the nitrile (Linnemann, *A.* 148, 251; Beckurts & Otto, *B.* 10, 262).—3. By heating lactic acid with  $\text{HIAq}$  (Freund, *J. pr.* [2] 5, 446).

*Properties.*—Liquid, miscible with water, alcohol, ether, benzene, and ligroin. Separated from its aqueous solution by  $\text{CaCl}_2$ , but not by  $\text{NaCl}$  and  $\text{Na}_2\text{SO}_4$ . Heated in a sealed tube with  $\text{ICl}$ , it gives  $\text{C}_2\text{Cl}_4$ ,  $\text{CO}_2$ , and  $\text{HCl}$  (Kraft, *B.* 9, 1085). On boiling the dry acid with  $\text{Br}$  and  $\text{P}$  for some time the product is  $\alpha$ -bromo-propionic acid (Volhard, *A.* 242, 141).

*Salts.*— $\text{NH}_4\text{A}'$ .— $(\text{NH}_4)\text{HA}'_2$  (Sestini, *Z.* 1871, 34).— $\text{NaA}'$ . S. 99 at  $15^\circ$ ; 187 at  $100^\circ$  (R.). S. (alcohol) 2.4 at  $20^\circ$ , 3 at  $100^\circ$ .— $\text{NaA}'$  aq. — $\text{KA}'$  aq. deliquescent plates (Renard, *C. R.* 104, 913). S. (of  $\text{KA}'$ ) 178 at  $16^\circ$ ; 309 at  $100^\circ$ .— $\text{KHA}'_2$ .— $\text{LiA}'$  aq.— $\text{CaA}'_2$  aq. S. 64 at  $17^\circ$  (L.); 41 at  $0^\circ$ ; 39 at  $80^\circ$  (K.). Needles, insol. alcohol.— $\text{Ca}_2\text{HA}'_2$ , 5aq.— $\text{BaA}'_2$  aq. S. 60 at  $17^\circ$  (Linnemann, *A.* 160, 220); 43 at  $0^\circ$ ; 68 at  $80^\circ$  (von Krasnicki, *M.* 8, 605).— $\text{BaA}'_2$ , 6aq.— $\text{BaHA}'_2$ , 3aq (Mixer, *Am.* 8, 343).— $\text{SrHA}'_2$ , 3aq: long thin crystals. [ $67\text{--}75^\circ$ ].— $\text{SrA}'_2$ , 6aq. Crystals.— $\text{Ba}_2\text{Mg}_2\text{A}'_4$ , 12aq (Fitz, *B.* 13, 1312; 14, 1035).— $\text{Mg}_2\text{Pb}_2\text{A}'_4$ , 12aq.— $\text{Ca}_2\text{Pb}_2\text{A}'_4$ , 12aq: monometric crystals.— $\text{BaCa}_2\text{A}'_4$ : monometric octahedra.— $\text{SrCa}_2\text{A}'_4$ .— $\text{MgA}'_2$  aq.— $\text{Ba}_2\text{A}'_4\text{Ac}_2$  (Fitz, *B.* 11, 1897).— $\text{PbA}'_2$ . [ $100^\circ$ ]. Crystalline mass.— $\text{Pb}_2\text{A}'_4\text{O}_2$ . S. c. 11 at  $14^\circ$ .— $\text{Pb}_2\text{A}'_4\text{O}$ . S. 8.8 at  $20^\circ$ ; 6.3 at  $85^\circ$ .— $\text{CuA}'_2$  aq: green prisms.— $\text{Cu}_2\text{A}'_4\text{O}$  aq.— $\text{CdA}'_2$ . V. e. sol. water.— $\text{ZnA}'_2$  aq: needles. S. (of  $\text{ZnA}'_2$ ) 32 at  $15^\circ$ .— $\text{HgA}'_2$ . [ $110^\circ$ ]. S. 19.2 at  $15^\circ$ .— $\text{HgA}'_2$ . [ $225^\circ$ ]. *Methyl ether MeA'*. ( $80^\circ$ ). S.G.  $\frac{4}{4}$  9373 (Elsässer, *A.* 218, 313);  $\frac{5}{5}$  9403 (Gartenmeister). C.E. ( $0^\circ$ – $10^\circ$ ) 001296.  $\mu_D = 1.3812$ . H.F.p. 107.330. H.F.v. 105.010 (Thomsen, *Th.*). S.V. 104.6.

*Ethyl ether EtA'*. Mol. w. 102. ( $99^\circ$  cor.). S.G.  $\frac{4}{4}$  9124 (E.);  $\frac{15}{15}$  8958;  $\frac{25}{25}$  8863. M.M. 5.452 at  $15.7^\circ$  (Perkin). C.E. ( $0^\circ$ – $10^\circ$ ) 001215. S.V. 127.7 (B. Schiff, *A.* 220, 110). Formed from  $\text{AgA}'$  and  $\text{EtI}$  and also by distilling the acid with alcohol and  $\text{H}_2\text{SO}_4$ . Oil.

**Propyl ether PrA'**. (123° cor.). S.G.  $\frac{2}{3}$  9619 (Elsässer, A. 218, 321);  $\frac{1}{4}$  8868;  $\frac{2}{3}$  8781 (Perkin, C. J. 45, 497);  $\frac{2}{3}$  9023 (Gartenmeister). M.M. 6.429 at 21.3°. C.E. (0°-10°) 001052. S.V. 150.

**Isopropyl ether PrA'**. (110° cor.). S.G.  $\frac{2}{3}$  8931 (Pribram a. Handl, M. 2, 687);  $\frac{1}{4}$  8717;  $\frac{2}{3}$  8626. M.M. 6.595 at 14°.

**n Butyl ether C<sub>4</sub>H<sub>9</sub>A'**. (145°). S.G.  $\frac{2}{3}$  8953. S.V. 173.2. C.E. (0°-10°) 00106 (Gartenmeister, A. 233, 265).

**Isobutyl ether PrCH<sub>3</sub>A'**. (137°). S.G.  $\frac{2}{3}$  8876. C.E. (0°-10°) 001015 (E.). S.V. 174 (R. Schiff, A. 220, 332).

**Isoamyl ether C<sub>5</sub>H<sub>11</sub>A'**. Mol. w. 144. (160°). S.G.  $\frac{2}{3}$  8877 (Elsässer, A. 218, 330). C.E. (0°-10°) 00099. S.V. 197 (Schiff); 195 (E.).

**Heptyl ether C<sub>7</sub>H<sub>15</sub>A'**. (208°). S.G.  $\frac{2}{3}$  8847. C.E. (0°-10°) 00096. S.V. 247.1 (Gartenmeister).

**Octylether C<sub>8</sub>H<sub>17</sub>A'**. (226°). S.G.  $\frac{2}{3}$  8833. C.E. (0°-10°) 00093. S.V. 270.5 (Gartenmeister).

**Ethylene ether C<sub>2</sub>H<sub>4</sub>A'**. (211° cor.). S.G.  $\frac{1}{4}$  1.0544 (Perkin, C. J. 45, 505).

**Phenyl ether PhA'**. (200° i.V.) at 744 mm.

**Chloride C<sub>2</sub>H<sub>5</sub>COCl**. (80°). S.G.  $\frac{2}{3}$  1.0646 (Brühl, A. 203, 14; cf. Sestini, B. [2] 11, 470).  $\mu_D = 1.4107$ .  $R_D = 34.12$ . ZnMe<sub>2</sub>, followed by water, forms methyl ethyl ketone and oily C<sub>2</sub>H<sub>5</sub>O (168°). S.G.  $\frac{2}{3}$  877 (Pawloff, A. 188, 138).

**Bromide C<sub>2</sub>H<sub>5</sub>OBr**. (104° i.V.). S.G.  $\frac{2}{3}$  1.52 (Lobry de Bruyn, R. T. C. 3, 389).

**Iodide C<sub>2</sub>H<sub>5</sub>OI**. (128°).

**Anhydride (C<sub>2</sub>H<sub>3</sub>O)<sub>2</sub>**. Mol. w. 130. (162°) at 708 mm. (L.); (165°) (Limpriat a. Uslar, A. 94, 322); (167°) (Kahlbaum, B. 16, 2481); (169°) (Perkin, C. J. 28, 10). Formed by the action of Pb(NO<sub>3</sub>)<sub>2</sub> (also of nitrates of other heavy metals) upon propionyl chloride; PbCl<sub>2</sub> is formed, and N<sub>2</sub>O and oxygen evolved; the yield is 77 p.c. of theoretical (Lachowicz, B. 18, 2991). Reacts with hydroxylamine hydrochloride, forming CH<sub>3</sub>.CH<sub>2</sub>.C(OH).NOH [85°] (Miolati, B. 25, 700).

**Amide C<sub>2</sub>H<sub>5</sub>NO**, i.e. C<sub>2</sub>H<sub>5</sub>.CO.NH<sub>2</sub>. Mol. w. 73. [79°]. (213°). H.C.p. 436,000. H.C.v. 435,600. H.F. 88,400 (Berthelot, C. R. 111, 145; A. Ch. [6] 22, 20; B. [3] 4, 229). Formed from propionic ether and NH<sub>3</sub> (Dumas, C. R. 25, 657; Sestini, Cimento, 4, 21; L. Meyer, B. 22, 24). Prepared by heating ammonium propionate at 230° under pressure; the yield being 55 p.c. of the theoretical amount (Hofmann, B. 15, 981). Got also by heating propionic acid (46 g.) with ammonium sulphocyanide (18 g.) for 4 days, and distilling the product (J. Schulze, J. pr. [2] 27, 517).—B<sub>2</sub>HCl. Needles, v. a. sol. water, v. sl. sol. ether.—Hg(NH.C<sub>2</sub>H<sub>5</sub>O)<sub>2</sub>. Large dimetric plates, sl. sol. cold water.

**Bromo-amide C<sub>2</sub>H<sub>5</sub>O.NHBr**. [80°]. Formed from propionamide, bromine, and KOHAq (Hofmann, B. 15, 753). Colourless needles, sol. alcohol. Converted by hot KOHAq into ethylamine.—C<sub>2</sub>H<sub>5</sub>O.NNaBr. [c. 100°]. Needles.

**Acetyl-amide C<sub>2</sub>H<sub>5</sub>O.NHAc**. [82°]. (230°-240°). Formed from propionamidine hydrochloride, NaOAc, and Ac<sub>2</sub>O, a compound C<sub>2</sub>H<sub>5</sub>N,

[204°] being formed at the same time (Pinner, B. 22, 1604).

**Imide (C<sub>2</sub>H<sub>3</sub>O)<sub>2</sub>NH**. [154°] (Otto a. Tröger, B. 23, 759). (210°-220°). **Formation**.—1. By heating the amide in a current of HCl.—2. By heating the amide with the chloride and AlCl<sub>3</sub>.—3. By the action of AlCl<sub>3</sub> at 100° on a mixture of propionitrile with AcCl or propionyl chloride.—4. By heating propionic acid with propionitrile for some hours at 200°. **Properties**.—Rectangular tables or silky needles, sl. sol. cold water. May be sublimed.

**Anilide C<sub>2</sub>H<sub>5</sub>ONHPh**. [105°]. S. 42 at 24°. Formed by heating the amide with aniline (Kolbe, B. 16, 1200). Plates, sol. ether. With oxalic ether, benzene, and NaOEt it forms CO.CO > NPh [192°] (Wislicenus a. Sattler, B. 24, 1256).

**Methyl-arilide C<sub>2</sub>H<sub>5</sub>O.NPhMe**. [58.5°]. Formed from the anilide and MeI (Norton a. Allen, B. 18, 1998).

**Ethyl-p-toluide C<sub>2</sub>H<sub>5</sub>O.NHCH<sub>3</sub>Me**. (c. 270°). From the chloride and ethyl-toluidine (Norton a. Livermore, B. 20, 2271).

**Nitrile C<sub>2</sub>H<sub>3</sub>N**, i.e. Et.CN. **Propionitrile**. **Ethyl cyanide**. (97°). S.G.  $\frac{1}{4}$  7998;  $\frac{2}{3}$  7815 (Perkin, C. J. 55, 701);  $\frac{1}{4}$  8010 (Thorpe). C.E. (0°-10°) 00125; (0°-100°) 00148. M.M. 8.831.  $\mu_D$  1.3659 at 24° (Gladstone, C. J. 59, 290). H.F.p. -9.670 (Thomson, Th.); +8.700 (from diamond) (Berthelot, C. R. 108, 1219). H.F.v. -10.830. H.C. 446,700 (Berthelot); 471,460 (Thomson, Th. 4, 129). S.V. 78.4. **Formation**.—1. By distilling dry KCy with K<sub>2</sub>SO<sub>4</sub> or Ba(EtSO<sub>4</sub>)<sub>2</sub> (Pelouze, A. 10, 249).—2. By boiling KCy with EtI and alcohol (Williamson, P. M. [4] 6, 205; Buckton a. Hofmann, C. J. 9, 250; Rossi, A. 159, 79).—3. From the amide and P<sub>2</sub>O<sub>5</sub> (Dumas, A. 64, 394).—4. From ZnEt<sub>2</sub> and cyanogen or CyCl (Gal. 2, 1868, 252; Frankland a. Graham, C. J. 37, 740).—5. By the action of Ac<sub>2</sub>O on the oxim of propionic aldehyde in the cold (Dollfus, B. 25, 1915). **Preparation**.—The nitrile cannot be freed from alcohol by distillation, since the compound C<sub>2</sub>H<sub>5</sub>N<sub>3</sub>HOEt boils constantly at 79°, and is not decomposed by water or CaCl<sub>2</sub>. It is best, therefore, to prepare it from the amide. **Properties**.—Colourless liquid, v. sol. water, but separates on addition of NaCl or CaCl<sub>2</sub>. Miscible with alcohol and ether. Combines with metallic chlorides, yielding (C<sub>2</sub>H<sub>3</sub>N)SbCl<sub>3</sub>, (C<sub>2</sub>H<sub>3</sub>N)AuCl<sub>4</sub>, (C<sub>2</sub>H<sub>3</sub>N)PtCl<sub>6</sub>, (C<sub>2</sub>H<sub>3</sub>N)<sub>2</sub>SnCl<sub>6</sub>, and (C<sub>2</sub>H<sub>3</sub>N)<sub>2</sub>TiCl<sub>6</sub> (Henke, A. 106, 280). Forms also (C<sub>2</sub>H<sub>3</sub>N)<sub>2</sub>FeCy<sub>2</sub> 6aq, (C<sub>2</sub>H<sub>3</sub>N)<sub>2</sub>FeCy<sub>2</sub>EtCl 6aq (Buff, A. 91, 253), and (EtCy)<sub>2</sub>PtCy<sub>2</sub> 2aq (Thian, A. 107, 315). **Reactions**.—1. **Potash** forms propionic acid. Dilute H<sub>2</sub>SO<sub>4</sub> acts in like manner. 2. Dry **chlorine** forms CH<sub>3</sub>.CCl<sub>2</sub>.CN (Otto, A. 116, 195).—3. **Bromine** forms C<sub>2</sub>H<sub>5</sub>NBr<sub>2</sub> [64°], converted by water into (C<sub>2</sub>H<sub>5</sub>BrO).NH (Engler, A. 142, 65).—4. Dry HCl slowly forms C<sub>2</sub>H<sub>5</sub>NCl [121°] (Gautier, A. 142, 289), while HBr gives C<sub>2</sub>H<sub>5</sub>NBr<sub>2</sub> [50°-55°] (Engler, A. 149, 807). HI below 0° forms EtCl.NH<sub>2</sub>, crystallising in plates (Biltz, B. 25, 2542).—5. **Sodium** converts it on heating into the polymeric cyanethine (q. v.). Sodium added to its solution in dry ether gives off H and ethane, and forms a product which is left when the ether is evaporated as a white powder (Et.C(NH).CMeNa.CN?). This powder is con-

verted by water into  $C_2H_5N_2$ ,  $[48^\circ]$  ( $258^\circ$  uncor.), and by HClAq into  $C_2H_5NO$  or  $C_2H_5.CO.CHMe.CN$  ( $198.5^\circ$ ). The white powder treated with MeI yields  $C_2H_5N_2$ ,  $[48^\circ]$  ( $252^\circ$ ), whence HClAq forms liquid  $C_2H_5NO$  ( $175^\circ$ ), S.G.  $\pm .945$ , mol. w. 125 (obs.). EtI and HClAq acting on the white powder yield  $C_2H_5NO$  ( $195^\circ$ ), S.G.  $\pm .943$  (E. von Meyer, *J. pr.* [2] 38, 336; Hanriot a. Bouveault, *C. R.* 108, 1171; B. [3] 1, 551). The compounds  $C_2H_5NO$  and  $C_2H_5NO_2$  are converted by heating with HClAq in sealed tubes into ethyl isopropyl ketone and ethyl butyl ketone respectively.—6. A mixture of propionitrile and benzonitrile in ethereal solution is converted by Na, followed by water, into  $CPh(NH).CHMe.CN$  ( $97^\circ$ ), whence warm dilute HClAq forms oily  $C_2H_5.CO.CHMe.CN$  (E. von Meyer, *J. pr.* [2] 39, 189).—7. Zinc and HClAq yield propylamine together with smaller quantities of di- and tri-propylamine (Pisanello, *G.* 16, 446).— $Ac_2O$  at  $200^\circ$  forms  $C_2H_5N_2O_2$  ( $68^\circ$ ) ( $220^\circ$ ) (Gautier, *Z.* 1869, 127).

**References.**—AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, CHLORO-BROMO-, IODO-, NITRO-, and OXY-AMIDO-PROPIONIC ACID and PROPIONITRILE.

**PROPIONIC ALDEHYDE**  $C_2H_5O$  *i.e.*  $CH_3.CH_2.CHO$ . Mol. w. 58. ( $48^\circ$ ). S.G.  $\frac{1}{4}$  .8065;  $\frac{2}{3}$  .7966 (Perkin, *C. J.* 45, 476);  $\frac{2}{3}$  .8066 (Brühl, *A.* 203, 13). S. 16 at  $20^\circ$ . MM. 3.332 at  $13.8^\circ$ .  $\mu_D$  1.368.  $n_D^{20}$  = 25.42. S.V. 75.4. H.F.p. 55.240. H.F.v. 53.790 (Thomson). Formed by oxidation of propyl alcohol (Michaelson, *A.* 134, 69; Chancel, *A.* 151, 801; Lieben a. Zeisel, *M.* 4, 14) and by distilling calcium formate with calcium propionate (Rossi, *C. R.* 70, 129). Pungent liquid, sol. water. Readily oxidised by air. Reduces ammoniacal  $AgNO_3$ , forming a mirror. Readily dissolves in aqueous  $NaHSO_3$ . Decomposed by hot KOHAq. Coloured brownish-red by alkaline sodium nitroprusside, the colour being destroyed by  $HOAc$  (Von Bitto, *A.* 267, 876).

**Reactions.**—1. Reduced in aqueous solution by sodium-amalgam to *n*-propyl alcohol.—2.  $H_2S$  passed into its aqueous solution, acidified by HCl, forms oily  $(C_2H_5S)C_2H_5O$  (Alexejeff, *B.* 10, 1739).—3. Dry ammonia passed into propionic aldehyde dissolved in ligroin cooled by a freezing mixture forms a white flocculent pp. of  $C_2H_5(OH)NH_2$ , which readily deliquesces, forming  $C_2H_5H_2N_2$ ,  $[74^\circ]$ , crystallising in triclinic tables,  $a:b:c$  = 1:1.185:801, insol. water, sol. alcohol and ether (Waage, *M.* 4, 708).—4.  $PH_3$  and HCl form  $(CH_3.CH_2.CHO).PH_3Cl$  ( $128^\circ$ ), while  $PH_3$  and  $HBr$  give  $(C_2H_5O).PH_3Br$  ( $106^\circ$ ). These compounds are decomposed by water (Messinger a. Engels, *B.* 21, 331).  $PH_3I$  at  $0^\circ$  forms, in like manner,  $(C_2H_5O).PH_3I$  ( $96^\circ$ ) (Girard, *A. Ch.* [6] 2, 24).—5. Mercaptan and  $ZnCl_2$  give  $CH_3.CH_2.CH(SET)$ , ( $198^\circ$ ) (Fromm, *A.* 253, 150). 6. Propyl alcohol and  $HOAc$  at  $100^\circ$  form  $CHET(OPr)$ , ( $166^\circ$  cor.) (Schudel, *M.* 5, 247).

**Oxim**  $C_2H_5.CH.NOH$ . ( $131^\circ$ ). Formed from the aldehyde and aqueous hydroxylamine (Petracek, *B.* 15, 2784). Liquid, sol. water. It is a *syn*-oxim, because it is converted by  $Ac_2O$  and ether in the cold into propionitrile (Dollfus, *A.* 25, 1915).

**Phenyl-hydrazide**  $CHET.N_2.HPh$  ( $152^\circ$  *in vacuo*) (Bischoff, *B.* 23, 1916).

**References.**—BROMO-, CHLORO-, IODO-, and OXY-PROPIONIC ALDEHYDE.

#### PROPIONIC IMIDO-ETHYL ETHER

$C_2H_5.C(NH).OEt$ . The hydrochloride,  $B'HCl$ , formed by passing gaseous HCl into a mixture of propionitrile and alcohol diluted with ether ( $\frac{1}{3}$  vol.), crystallises in prisms, decomposing at about  $92^\circ$  into EtCl and propionamide (Pinner, *B.* 16, 1654).

**PROPIONITRILE** *v.* Nitrile of PROPIONIC ACID.

**PROPIONYL-ACETOPHENONE** *v.* PHENYL-METHYLENE-ETHYL-DIKETONE.

**PROPIONYL-BENZOIC ACID** *v.* PHENYL-ETHYL KETONE CARBOXYLIC ACID.

**PROPIONYL BROMIDE** *v.* Bromide of PROPIONIC ACID.

#### PROPIONYL-BUTYRIC ACID

$C_2H_5.CO.CMe.CO_2H$ .

*Methyl ether* MeA'. ( $188^\circ$  uncor.). Formed by the action of MeOH and HCl on the nitrile  $C_2H_5.CO.CMe.CN$  ( $175^\circ$ ), which is got by the action of cold HCl upon  $C_2H_5.C(NH).CMe.CN$  ( $43^\circ$ ) which is made by the action of MeI on the product of the action of Na on propionitrile (Bouveault, *C. R.* 111, 531). Liquid.

**PROPIONYL CHLORIDE** *v.* Chloride of PROPIONIC ACID.

#### PROPIONYL CYANIDE $C_2H_5NO$ *i.e.*

$CH_3.CH_2.CO.CN$ . ( $109^\circ$ ). Prepared by heating propionyl chloride (12 g.) with silver cyanide (8 g.) in closed tubes for 1 hour at  $100^\circ$ . The product is fractionally distilled (Claisen a. Moritz, *C. J.* 37, 692). HCl converts it into ethylglyoxylic acid (*q. v.*).

**Di-propionyl di-cyanide**  $(Et.CO)_2C_2N_2$ . ( $59^\circ$ ). ( $208^\circ$ ). V.D. 5.6 (calc. 5.7). Obtained in the preparation of the preceding (C. a. M.) and by the action of AgCy on propionyl bromide (Lobry de Bruyn, *R. T. C.* 3, 390). Prisms, sl. sol. water, sol. alcohol and ether.

**PROPIONYL-CYANO-ACETIC ETHER** *v.* CYANO-ACETIC ACID.

#### PROPIONYL-MALONIC ETHER $C_6H_9O_4$

*i.e.*  $C_2H_5.CO.CH(CO_2Et)_2$ . ( $239^\circ$ – $242^\circ$  uncor.). Formed by the action of propionyl chloride upon sodio-malonic ether (Lang, *B.* 20, 1326). Colourless liquid.

**PROPIONYL-PHENOL** *v.* OXY-PHENYL-ETHYL KETONE.

**$\alpha$ -PROPIONYL-PROPIONIC ACID  $C_6H_9O_4$**  *i.e.*  $CH_3.CH_2.CO.CHMe.CO_2H$ .

*Methyl ether*  $C_2H_5.CO.CHMe.CO_2Me$  or  $C_2H_5.C(OH).CMe.CO_2Me$ . ( $187^\circ$  cor.). S.G.  $\frac{22}{107}$ . Formed by the action of Na on methyl propionate (Pingel, *A.* 245, 84). Colourless liquid with aromatic odour. Converted by ammonia into  $C_2H_5NO_2$  and a hygroscopic substance  $C_2H_5N_2O_4$  (?) ( $82^\circ$ ). Aniline forms oxy-methyl-ethyl-quinoline [ $295^\circ$ ] (Bouveault, *C. R.* 111, 41). NaOHAq yields a mixture of di-ethyl ketone and methyl ethyl ketone. NaOEt followed by alkyl iodides yields the alkyl derivatives:  $C_2H_5MeO$ , or  $CEt(OMe).CMe.CO_2Me$  ( $194^\circ$ ),  $C_2H_5EtO$ , ( $208^\circ$ ),  $C_2H_5PrO$ , ( $220^\circ$ ), and  $C_2H_5(CHEt)O$ , ( $231^\circ$ ), all being liquid.

*Ethyl ether* EtA'. ( $199^\circ$ ). S.G.  $\frac{2}{15}$  .995;  $\frac{15}{15}$  .983. Formed by digesting propionic ether in  $Et_2O$  with Na (Oppenheim a. Hellon, *B.* 10, 699; Israel, *A.* 231, 197). Gives no colour with  $FeCl_3$ . Ammonia forms  $C_2H_5NO_2$  ( $195^\circ$ ), insol.

water, and a hygroscopic substance [75°]. NaOH aq. forms di-ethyl ketone. NaOEt and EtI yield propionic ether and  $\text{CH}_3\text{CH}_2\text{CO}_2\text{H}$  (Genther, *A.* 239, 886). Na followed by EtI added to the solution in benzene forms  $\text{C}_2\text{H}_5\text{C(OEt):CMe.CO}_2\text{Et}$  (206°). S.G. 12 -966. Reduced by HI and P to  $\text{CHMePr.CO}_2\text{H}$  (193°). Nitrous acid yields  $\text{CH}_2\text{C(NO)(OH).CO}_2\text{Et}$  [94°] (Hantzsch a. Wohlbrück, *B.* 20, 1320).

**Amide**  $\text{C}_2\text{H}_5\text{O.CHMe.CO.NH}_2$ . [153°]. Formed by adding water to the product of the action of AlCl<sub>3</sub> on a mixture of propionyl chloride and propionitrile (Otto a. Tröger, *B.* 22, 1455). Needles, sl. sol. cold water.

**Nitrile**  $\text{C}_2\text{H}_5\text{CO.CHMe.CN}$ . (c. 188°). Formed by the action of cold conc. HCl aq. on the product of the action of Na on propionitrile (Meyer, *J. pr.* [2] 38, 339). Oil. Converted by ammonia into the imide [45°]. Hydroxylamine forms the oxim  $\text{C}_2\text{H}_5\text{C(ONH).CHMe.CN}$  [44°] (180° at 200 mm.) (Hanriot, *C. R.* 112, 796). Aniline yields amido-methyl-ethyl-quinoline (Hanriot a. Bouveault, *Bl.* [3] 1, 552).

**Propionyl-propionic acid**  
 $\text{CH}_3\text{CH}_2\text{CO.CH}_2\text{CH}_2\text{CO}_2\text{H}$ . [33°]. A product of the action of boiling water on di-bromo-hexioic acid (from hydrosorbic acid and Br) (Fittig, *A.* 268, 69). Crystalline, v. c. sol. water, alcohol, and ether. —  $\text{CaA}_2$  1 aq. plates. — AgA'.

**PROPIONYL-PROPIONIC ALDEHYDE**  
 $\text{C}_2\text{H}_5\text{CO.CHMe.CHO}$ . [c. 40°]. (165°). Formed by adding a well-cooled mixture of formic ether (11 g.) and di-ethyl ketone (13 g.) to NaOEt (10.5 g.) suspended in dry ether (10 g.). After 12 hours the product is acidified and distilled under 50 mm. pressure (Claisen a. Meyrowitz, *B.* 22, 3273). Crystals, v. sol. water. Deliquesces and turns brown in air. NH<sub>3</sub> forms deliquescent crystals of  $(\text{C}_2\text{H}_5\text{O})_2\text{NH}_2$ .  $\text{Cu(OAc)}_2$  added to its alcoholic solution forms  $\text{Cu(C}_2\text{H}_5\text{O}_2)_2$  [168°]. Phenyl-hydrazine produces  $\text{C}_{12}\text{H}_{15}\text{N}_2$  (283°).

**PROPIOPHENONE** v. **PHENYL ETHYL KETONE**.  
**PROPYL**. The radicle  $\text{C}_2\text{H}_5$ . *n*-Propyl  $\text{CH}_3\text{CH}_2\text{CH}_2$  changes in some reactions to isopropyl  $(\text{CH}_3)_2\text{CH}$  and *vice versa*.

*Pr* changes to *Pr*: 1. When cumyl alcohol is reduced to *n*-cymene by boiling with zinc-dust (Kraut, *A.* 192, 225; Jacobsen, *B.* 12, 431). — 2. When cumyl chloride is reduced to *n*-cymene by zinc and HCl (J. 1879, 369). — 3. When nitro-cumylene chloride is reduced to *n*-cymidine by boiling with zinc and HCl (Widman, *B.* 15, 166; 19, 245). — 4. When isopropyl-cinnamic acid is reduced by sodium-amalgam to *n*-cumyl-propionic acid. — 5. When *o*-amido-isopropyl-cinnamic acid is reduced by sodium-amalgam to (B. 5)-*n*-propyl-(Py. 3)-oxy-quinoline dihydride.  
*Pr* changes to *Pr*: 1. When *n*-cymene is oxidised to cuminic acid—(a) by passing through the organism, (b) by air and gaseous NaOH (*B.* 5, 749; 12, 512; 11, 369; 14, 1144). — 2. When *n*-cymene sulphonic acid is oxidised to oxyisopropyl-sulpho-benzoic acid by alkaline  $\text{KMnO}_4$  (Meyer a. Boner, *B.* 14, 1136, 2391; *A.* 220, 6). — 3. When *n*-cymene is oxidised to oxyisopropyl-benzoic acid by alkaline  $\text{KMnO}_4$ . — 4. When thymol is oxidised by KOH fusion to the oxy-cuminic acid, which is obtained from *m*-nitro-cuminic acid by reduction and diazotisation (Barth, *B.* 11, 1571). — 5. When carvacrol (which contains *n*-propyl, since by distillation with  $\text{P}_2\text{S}_5$ ,

it gives *n*-cymene) is oxidised by KOH fusion to the oxy-cuminic acid [93°], which is obtained from *o*-amido-cuminic acid by diazotisation (*B.* 6, 936; 9, 1061). — 6. Since cuminal is always accompanied in plants by *n*-cymene, it is probably produced by oxidation of the latter. — 7. When *n*-propyl bromide is boiled with  $\text{AlBr}_3$  (Gustavson, *C. J.* 44, 565).

From the above may be deduced the general law: When a propyl group in a benzene derivative occurs in the para-position to Me, CHO, or CO<sub>2</sub>H, it is predisposed to be normal by Me, iso by CHO or CO<sub>2</sub>H (Widman, *B.* 19, 251, 273, 2769, 2781; cf. Filici, *G.* 16, 300, 497).

Dipropyl v. **HEXANE**.

DI-PROPYL-ACETAL v. **ALDEHYDE**.

PROPYL ACETATE v. **Acetyl derivative of**  
**PROPYL ALCOHOL**.

PROPYL-ACETIC ACID v. **VALERIC ACID**.

Di-propyl-arstic acid v. **OUTONIC ACID**.

PROPYL-ACETOACETIC ETHER v. **vol. i.**  
**p. 23**.

DI-PROPYL-ACETONE v. **METHYL HEPTYL**  
**KETONE**.

PROPYL-ACETYLENE v. **PENTINENE**.

DI-PROPYL-ACRYLIC ACID v. **ENNECOIC**  
**ACID**.

*n*-PROPYL ALCOHOL  $\text{C}_3\text{H}_7\text{O}$  *lc.*

$\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ . Mol. w. 60. (97.4° V.). S.G.  $\frac{4}{17}$  (Zander, *A.* 224, 79);  $\frac{15}{15}$  -8088;  $\frac{25}{25}$  -8025 (Perkin);  $\frac{20}{20}$  -8044 (Brühl, *A.* 203, 268). C.E. ( $0^\circ$ -10°) -00082. M.M. 3.77 at 15.6°.  $\mu_p$  1.3901.  $R_p$  28.0. H.F.p. 82,000 (Berthelot); 65,690 (Thomsen). S.V. 81.3 (H. Schiff, *A.* 220, 101). S.H. -670 (Diacomoff, *Bl.* [2] 38, 172). Occurs in fusel oil, especially in that of wine (Chancel, *C. R.* 37, 410; 68, 659, 726; Pierre a. Puchot, *C. R.* 66, 302; 70, 406; Linneemann, *A.* 160, 195; Fittig, *Z.* [2] 4, 44; Ekman, *Chem. Zeit.* 12, 561). Thus 40 g. of it were found in 100 litres of old cognac (Ordonneau, *C. R.* 102, 217; Clandon a. Morin, *C. R.* 104, 1187; 105, 1019). A litre of potato-fusel oil was found to contain 30 c.c. of *n*-propyl alcohol, 150 c.c. of isopropyl alcohol, 115 c.c. of butyl alcohols, 335 c.c. of amyl alcohols, 125 c.c. of water, and 245 c.c. of other bodies (Rabuteau, *C. R.* 87, 501). Propyl alcohol also occurs, together with isopropyl alcohol, among the products of the lactic and butyric fermentation of sugar (Bouchardat, *C. R.* 78, 1145; Meyer a. Forster, *B.* 9, 535), and in the fermentation of glycerin (Fitz, *B.* 18, 86, 1311).

**Formation**.—1. By reducing propionic aldehyde with sodium-amalgam (Linneemann, *A.* 148, 251; 160, 231; 161, 18). — 2. By adding sodium-amalgam and dilute  $\text{H}_2\text{SO}_4$  to a solution of propionic aldehyde (1 pt.) in water (18 pts.) (Rossi, *C. R.* 70, 129). — 3. By heating allyl alcohol with KOH (Tollens, *Z.* [2] 7, 242).

**Properties**.—Liquid with alcoholic odour, miscible with water, but separated from the solution by  $\text{CaCl}_2$ . Does not yield isopropyl alcohol when heated in sealed tubes (Aronstein, *R. T. C.* 1, 134). When propyl alcohol (71.45 c.c.) is mixed with water (28.54 c.c.), contraction (1.85 c.c.) is observed (Ramsay a. Young, *C. J. Proc.* 4, 101).

**Reactions**.—1. Chromic acid oxidises it to propionic aldehyde and acid. — 2. HBr and  $\text{H}_2\text{SO}_4$  give propyl bromide, propylene bromide,

and  $C_2H_5Br$ , (Niemilovitch, *M.* 10, 820).—3. **I** and  $KOHAq$  form iodoform (Lieben, *A. Suppl.* 7, 280).—4. Fused  $ZnCl_2$  forms propylene, isobutyl alcohol,  $CH_3.CMe_2$ , and  $CHMe.CHMe$  (Le Bel a. Greene, *C. R.* 89, 413).—5. **Phosphoplatinous chloride** followed by water forms crystalline  $P(OPr)_2.PtCl_2$  (Pomey, *C. R.* 104, 364).—6. **Calcium chloride** yields  $(C_2H_5O)_2CaCl_2$  crystallising in needles (Göttig, *B.* 23, 181).

**Metallic derivatives.**  $KOPr$  (De Forcrand, *C. R.* 104, 68).— $NaOPr.2HOPr$  (Fröhlich, *A.* 202, 295).  $Ba_2(OPr)_2(OH)_2$ . Formed by heating propyl alcohol with  $BaO$  under pressure (Destrem, *A. Ch.* [5] 27, 32). Yields propylene, methane, and hydrogen when heated. The corresponding lime compound yields di-ethyl ketone when heated.— $Al(OPr)_3$ . [ $c$ . 60°]. S.G. 1.026. Formed in small quantity from propyl alcohol,  $AlI_3$ , and  $Al$  (Gladstone a. Tribe, *C. J.* 39, 6). Isopropyl alcohol does not react in this way.

**Acetyl derivative**  $PrOAc$ . *Propylacetate*. (102°). S. 1.5 at 16° (Linnemann, *A.* 161, 30). S.G.  $\frac{1}{4}$  .9091 (E.);  $\frac{2}{4}$  .8856 (Brühl);  $\frac{3}{4}$  .9093 (Gartenmeister);  $\frac{15}{4}$  .8933;  $\frac{25}{4}$  .8840 (Perkin, *C. J.* 45, 421). C.E. (0°-10°) .001197 (Eisässer, *A.* 218, 320). S.V. 1.28.3.  $\mu_D$  1.3890.  $R_{\infty}$  43.11. M.M. 6.487 at 15.2°. Liquid. Not changed into isopropyl acetate by heating in a sealed tube (Aronstein, *R. T. C.* 1, 134).

**Benzoyl derivative**  $BzOPr$ . (230° cor.). S.G.  $\frac{1}{4}$  1.032 (Linnemann).

**Isopropyl alcohol**  $(CH_3)_2CH.OH$ . (83° cor.). S.G.  $\frac{1}{4}$  .7996 (Zander);  $\frac{15}{4}$  .7914;  $\frac{25}{4}$  .7815 (Perkin);  $\frac{30}{4}$  .7887 (Brühl, *A.* 203, 12).  $\mu_D$  = 1.3821.  $R_{\infty}$  27.99. M.M. 4.019 at 17.9°. S.V. 81.7 (R. Schiff, *A.* 220, 331); 82.8 (Zander). C.E. (0°-10°) .00108. H.F.p. 71.000. H.F.v. 68,970 (Thomsen, *Th.*).

**Formation.**—1. By distilling  $PrO.SO_3H$  (made from propylene and  $H_2SO_4$ ) with water (Berthelot, *J.* 1855, 611).—2. By reducing acetone or propylene oxide with sodium-amalgam (Friedel, *A.* 124, 327; Linnemann, *A.* 140, 178).—3. By heating a solution of *n*-propylamine nitrite (Linnemann, *A.* 161, 43; *B.* 10, 1111; Meyer, *B.* 9, 535).—4. By the action of sodium-amalgam on  $(CH_3Cl).CH.OH$  dissolved in wet ether (Buff, *Z.* [2] 4, 124).—5. From  $CH_3I.CH_2OH$  by successive treatment with  $ZnMe_2$  and water (Butlerow a. Ossokin, *A.* 145, 257).

**Preparation.**—1. **Acetone** (1 vol.) is diluted with water (5 vols.) and sodium-amalgam is slowly added. The liquid is distilled and the process repeated upon the distillate (Linnemann, *A.* 186, 57).—2. By boiling isopropyl iodide (1 pt.) with water (10 pts.) and  $Pb(OH)_2$  (Flavitzky, *A.* 175, 380).—3. By heating isopropyl iodide (1 pt.) with water (20 pts.) at 100° for 40 hours (Niederist, *A.* 186, 391).

**Properties.**—Liquid with peculiar odour, not solid at -20°. Inactive to light. Miscible with water, yielding on distillation the hydrate  $(C_2H_5O)_2$  2aq (80°). S.G.  $\frac{1}{4}$  .832. When  $K_2CO_3$  is added to an aqueous solution of the alcohol a hydrate  $(C_2H_5O)_2$  aq separates (Erlenmeyer, *A.* 126, 802). After drying over  $CuSO_4$  the hydrate  $(C_2H_5O)_2$  aq (81°) S.G.  $\frac{1}{4}$  .800 is left. Dilute  $CrO_3$  forms acetone. **Bromine** forms acetone and  $PrBr$ .

**Acetyl derivative**  $PrOAc$ . *Isopropyl*

*acetate*. (91°). S.G.  $\frac{1}{4}$  .917 (Friedel, *A.* 124, 327; Pribram a. Handl, *M.* 2, 686).

**Benzoyl derivative**  $PrOBz$ . (218°) (Silva, *Bl.* [2] 12, 225). Liquid. Split up by distillation into benzoic acid and propylene (Linnemann, *A.* 161, 51).

**References.**—BROMO-, CHLORO-, CHLORO-iodo-, and Iodo-PROPYL ALCOHOL.

**PROPYL ALDEHYDE** v. PROPIONIC ALDEHYDE.

**PROPYL-DI-ALLYL-CARBINOL** v. DECINYL ALCOHOL.

#### PROPYLAMIDOACETIC ACID

$NHPr.CH_2.CO_2H$ . Formed from  $CH_2Br.CO_2Et$  and  $NH_4Pr$  (Chance, *Bl.* [3] 7, 409; *C. R.* 114, 756). Needles, v. sol. water and alcohol, insol. ether.— $(HA).H.PtCl_2$  aq.— $CuA_2$  2aq: crystals, v. sol. water and alcohol.

**PROPYL-AMIDO-ISOPROPYL ALCOHOL**  $C_3H_7.NO$  i.e.  $CH_3.CH(OH).CH_2.NHC_2H_5$ . Formed by heating allyl-propyl-amine with  $H_2SO_4$  (3 pts.) at 135° (Liebermann a. Paal, *B.* 16, 532).— $B_2H_3.PtCl_2$  2aq: nodules (from water).

**Di-propyl-amido-isopropyl alcohol**  $CH_3.CH(OH).CH_2.N(C_2H_5)_2$ . Formed in like manner from allyl-di-propyl-amine.— $B_2H_3.PtCl_2$ .

***n*-PROPYLAMINE**  $C_3H_7.N$  i.e.  $CH_3.CH_2.CH_2.NH_2$ . Mol. w. 59. (49°). S.G.  $\frac{1}{4}$  .7222;  $\frac{25}{4}$  .7144. H.F.p. 22.760. H.F.v. 20,420 (Thomsen, *Th.*). S.V. 85.6. M.M. 4.564 (Perkin, *C. J.* 55, 693).  $\mu_D$  = 1.3873 (Gladstone, *C. J.* 59, 290).

**Formation.**—1. By reduction of propionitrile. Using 36 g. of propionitrile, 500 g. alcohol, 200 g. water, zinc, and 500 g. of 20 p.c.  $HClAq$ , the yield is 9 g. (Mendius, *A.* 121, 129; Linnemann, *A.* 161, 44).—2. From *n*-propyl iodide by successive treatment with silver cyanate and  $KOHAq$  (Silva, *Z.* [2] 5, 638).—3. By heating *n*-propyl iodide with alcoholic  $NH_3$ , and distilling the product with potash. The fraction boiling below 78° is mixed with alcohol and oxalic ether, and the di-propyl-oxamide [161.5°] thus formed distilled with alcoholic potash (Vincent, *C. R.* 103, 208). *n*-Propyl iodide heated with conc.  $NH_4Aq$  for 13 hours at 100°-150° forms propylamine hydriodide and  $NPr_2I$  (Malbot, *A. Ch.* [6] 13, 480, 546).—4. When *n*-propyl chloride is heated with aqueous ammonia in equimolecular proportions at 140°-165°, one-fifth of the product is *n*-propylamine and is nearly all contained in the lower layer. The upper layer consists of free di- and tri-propyl-amines, water, and alcohol (Malbot, *C. R.* 104, 999).—5. By heating *n*-propyl nitrate with alcoholic  $NH_3$  at 100° (Wallach, *A.* 214, 311).

**Preparation.**—1. A mixture of equimolecular quantities of bromine and butylamine is run into an excess of a 10 p.c. solution of  $KOH$  at 60° and the propylamine distilled off; the yield is 80-90 p.c. (Hofmann, *B.* 15, 769). It may be dried over  $CaO$  and afterwards over  $Na$ .—2.  $PrCl$  (1 mol.) heated with aqueous  $NH_3$  (1 mol.), and enough alcohol to effect solution, in sealed tubes at 110° forms 45 p.c. propylamine, 35 p.c. di-propylamine, and 20 p.c. tri-propylamine (Chance, *Bl.* [3] 7, 405). The product is neutralised with  $HCl$ , the alcohol distilled off, cooled, filtered from separated  $NH_4Cl$ , the syrup mixed with  $NaOH$ , distilled, and fractionated.

The bases may be further purified by means of their oxalates.

**Properties.**—Mobile liquid with ammoniacal smell; mixes with water, becoming hot. When wet it boils at 78°-82°. Its aqueous solution ppts. salts of Cu and Fe, the pp. not dissolving in excess, but with AgNO<sub>3</sub> it gives a pp. sol. excess.

**Reactions.**—1. *Chromic acid* yields propionic acid (Chapman a. Thorpe, A. 142, 176).—2. *Nitrous acid* forms n- and iso- propyl alcohols and propylene (Meyer a. Forster, B. 9, 535).—3. *Benzoic aldehyde* forms C<sub>11</sub>H<sub>11</sub>CH:NP<sub>r</sub> (210°) (Zaunschirm, A. 245, 282).—4. *Oralic ether* added to a mixture of equal volumes of propylamine and water forms CONHPr.CONHPr and CO<sub>2</sub>H.CONHPr [110°], which yields CaA', 2aq. S. 138 at 17°.

**Salts.**—B'HCl. [153°] (Topsoë, J. 1833, 621).—B'HHgCl<sub>2</sub>.—B'HHgCl<sub>4</sub>.—B'HAuCl<sub>4</sub>.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>. Monoclinic crystals. — Oxalate. NH<sub>4</sub>Pr.C<sub>2</sub>H<sub>3</sub>O<sub>4</sub>, aq. Plates. S. 148 at 18°; S. (alcohol) 6 at 18°.—Picrate [135°].

**Nitramine** CH<sub>3</sub>.CH<sub>2</sub>.CH<sub>2</sub>.NH.NO<sub>2</sub>. (129° at 40 mm.). S.G. 1.102. Formed by heating PrN(NO<sub>2</sub>).CO<sub>2</sub>Et in a current of dry NH<sub>3</sub>, and decomposing the product with dilute H<sub>2</sub>SO<sub>4</sub> (Thomas, R. T. C. 9, 75). Liquid, crystallising at -23°. Decomposes at 142°. Sl. sol. water; decomposes carbonates. —PrNK.NO<sub>2</sub>. Formed by dissolving the nitramine in alcoholic potash and ppg. with ether. Small pearly plates, forming an alkaline solution in water.—PrNAg.NO<sub>2</sub>. Slender needles, blackening in light. AcCl yields N<sub>2</sub>O.

**Isopropylamine** (CH<sub>3</sub>)<sub>2</sub>CH.NH<sub>2</sub>. (32°). S.G. 1.690.

**Formation.**—1. By the action of HClAq on isopropyl-carbamine (Siersch, A. 144, 263; Gautier, C. R. 67, 723).—2. By running a mixture of bromine (1 mol.) and isobutyramide (1 mol.) into an excess of a 10 p.c. solution of KOH at 60°; the yield being 65 p.c. (Hofmann, B. 15, 763).—3. By reducing acetoxim dissolved in alcohol with sodium-amalgam and HOAc at 40° (Goldschmidt, B. 20, 723).—4. By heating isopropyl iodide with conc. NH<sub>4</sub>Aq (Malbot, C. R. 111, 650; cf. Jahn, M. 3, 166).

**Preparation.**—By reduction of a solution of acetone-phenyl-hydrazone (1 pt.) in 96 p.c. alcohol (10 pts.) by means of acetic acid (2½ pts.) and sufficient 67 p.c. sodium-amalgam, the temperature being kept below 25°; the yield is 70 p.c. of the theoretical (Tafel, B. 19, 1926).

**Properties.**—Mobile liquid, with ammoniacal smell, miscible with water. Converted by nitrous acid into isopropyl alcohol.

**Salts.**—B'HCl. [140°]. Deliquescent cubes.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>: orange plates, m. sol. Aq.

**Nitramine** PrNH.NO<sub>2</sub>. [-4°]. (91°). S.G. 1.098. Formed from PrN(NO<sub>2</sub>).CO<sub>2</sub>Et by successive treatment with dry NH<sub>3</sub> and dilute H<sub>2</sub>SO<sub>4</sub> (Thomas, R. T. C. 9, 78). Needles.—PrNK.NO<sub>2</sub>. Slender hygroscopic needles.—PrNAg.NO<sub>2</sub>. Thin plates. Converted by PrI into PrNPr.NO<sub>2</sub> (67° at 10 mm.).

**Di-n-propylamine** Pr.NH. (110°) (P.; C.); (98°) (V.). S.G. 1.7480; 1.7857 (Perkin, C. J. 55, 693). M.M. 7, 549.  $\mu_p$  = 1.4033 (Gladstone, C. J. 59, 290). A product of the action of alcoholic NH<sub>3</sub> on PrI at 100° (Vincent, C. R. 103, 208;

Bl. [2] 46, 287) or of aqueous NH<sub>3</sub> on PrCl at 190° (Malbot, C. R. 105, 676). Purified by means of its nitrosamine. Liquid with ammoniacal smell, sl. sol. water. The pps. that it forms with salts of Ag and Al are sol. excess; those with salts of Cu and Zn are insol. excess.

**Salts.**—B'H.C<sub>2</sub>O<sub>4</sub>. Flat needles. S. 5 at 17°. S. (alcohol) 33 at 18° (Chancel, Bl. [3] 7, 406). Picrate. [75°]. S. 2.2 at 19°. Melts under water at 45°.

**Nitrosamine** Pr.N.NO. (206°). S.G. 1.931. Liquid smelling like hay. Decomposed by HClAq, with formation of dipropylamine.

**Nitramine** Pr<sub>2</sub>N.NO<sub>2</sub>. A liquid, got from PrNK.NO<sub>2</sub> and PrBr (Thomas, R. T. C. 9, 79).

**Di-isopropylamine** Pr.NH. (84°). S.G. 1.722. A product of the action of alcoholic NH<sub>3</sub> on PrI at 100° (Van der Zande, R. T. C. 8, 202; cf. Siersch, Z. [2] 5, 145). Liquid with very ammoniacal odour, miscible with water.—B'M.NO<sub>2</sub>. [138°].—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>: orange tables.

**Nitrosamine** Pr<sub>2</sub>N.NO. [46°]. (195°). **Nitramine** Pr<sub>2</sub>N.NO<sub>2</sub>. (56° at 10 mm.). Formed from PrNAg.NO<sub>2</sub> and PrI (Thomas, R. T. C. 9, 82). Liquid.

**Tri-n-propylamine** Pr<sub>3</sub>N. (157°). S.G. 1.770; 1.760; 1.751 (Perkin). S.V. 223.1 (Zander, A. 214, 171). M.M. 11464.  $\mu_p$  = 1.4171 (Gladstone, C. J. 59, 290). C.E. (0°-10°) 0.0105. A product of the action of PrI on alcoholic NH<sub>3</sub> (V.). It is the chief product got by heating PrCl with conc. NH<sub>4</sub>Aq (Malbot, A. Ch. [6] 13, 480, 546). Purified by means of its picrate (Chancel, Bl. [3] 7, 407). Liquid with faintly ammoniacal odour, almost insol. water.—Picrate. S. 3 at 18°; S. (94 p.c. alcohol) 4.4 at 19°.

**Propyl-iodide** Pr.NI. The chief product of the action of PrI on NH<sub>4</sub>Aq at 150°-190°. Prisms. Yields (Pr<sub>2</sub>NCI).PtCl<sub>6</sub> and deliquescent Pr<sub>2</sub>NOH, which is decomposed by heat into Pr<sub>2</sub>N, propylene, and water (Roemer, B. 6, 784).

**References.**—BROMO-, CHLORO-, CHLORO-iodo-, and OXY- PROPYLAMINE.

#### PROPYL-ISOAMYL-GLYOXALINE

C<sub>6</sub>H<sub>5</sub>(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>N<sub>2</sub>. *Oxalisopropyl-butylins*. (251°). S.G. 1.920. Formed from propyl-glyoxaline and C<sub>2</sub>H<sub>5</sub>I (Itiegar, M. 9, 609).

**PROPYL ISOAMYL OXIDE** Pr.O.C<sub>2</sub>H<sub>5</sub>. (125°-130°) (Chancel, A. 151, 305).

**PROPYL-ANILINE** C<sub>6</sub>H<sub>5</sub>N. *Is. PhNHPr*. (222° i.v.) (Pictet a. Crépiaux, B. 21, 1111). S.G. 1.949. Formed by heating aniline with PrBr (Claus a. Roques, L. 16, 909; Wacker, A. 243, 290). Liquid. Salts.—B'HCl. [150°].—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>. [152°]. Large tables, v. sol. water.

**Formyl derivative** PhNPr.(CHO). (268° i.v.). S.G. 1.044. Got from formanilide and n-propyl bromide.

**Acetyl derivative** PhNPrAc. [48°]. (269° i.v.). Hexagonal plates (from ligroin).

**Nitrosamine**. Yellow oil.

**Isopropyl-aniline** PhNHPr (213° i.v.). Liquid. Yields an oily nitrosamine.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>. Red prisms (P. a. C.).

**Formyl derivative** PhNPr.NO. (264° i.v.). Formed from formanilide and PrBr.

**Acetyl derivative** PhNPrAc. [39°]. (268° i.v.). Transparent leaflets (from ligroin).

**Di-*n*-propyl-aniline**  $\text{NPhPr}_2$ . (245° i.v.): S.G.  $\frac{2}{3}$  9240. S.V. 243-1 (Zander, A. 214, 168). C.E. (0°-10°) 00081. Formed from aniline and  $\text{PrI}$  (Lippmann a. Fleissner, M. 3, 711).— $\text{B}_2\text{H}_6\text{PtCl}_6$ . Decomposed by water.

**Di-isopropyl-aniline**  $\text{NPhPr}_2$ . (220° i.v.): S.G.  $\frac{2}{3}$  9338. S.V. 235-4 (Zander). C.E. (0°-10°) 00087.

**References.**—NITRO- and NITROSO-PROPYL-ANILINE.

#### DI-PROPYL-ANTHRACENE DIHYDRIDE

$\text{C}_{20}\text{H}_{18}$ , i.e.  $\text{C}_6\text{H}_4\langle\text{CPr}_2\text{CH}_2\rangle\text{C}_6\text{H}_4$ . Formed from di-propyl-anthrone, III, and P at 140°-170° (Hallgarten, B. 22, 1070). Plates, getting soft at 47°.

#### Di-isopropyl-anthrancene dihydride

$\text{C}_{20}\text{H}_{18}$ , i.e.  $\text{C}_6\text{H}_4\langle\text{CH}\text{CH}_2\text{Pr}\rangle\text{C}_6\text{H}_4$ . [90°]. (above 360°). Formed by boiling  $\text{C}_6\text{H}_5\text{Pr}\cdot\text{CHCl}_2$  alone or with  $\text{ZnCl}_2$  (Errera, G. 14, 280). Amorphous yellow powder, insol. alcohol, sol. ether. Its solutions are red with green fluorescence.

#### PROPYL-ANTHRANOL. Propyl deriva-

tive.  $\text{C}_{20}\text{H}_{20}\text{O}$ , i.e.  $\text{C}_6\text{H}_4\langle\text{CPr}\text{C}(\text{OPr})\rangle\text{C}_6\text{H}_4$ . [72°]. Formed by boiling anthranol with KOHAq and  $\text{PrI}$  (Hallgarten, B. 22, 1070). Needles, sol. ether and alcohol, insol. alkalis. Chromic acid solution converts it in the cold into propyl-oxanthranol  $\text{C}_{21}\text{H}_{20}\text{O}_2$  [164°], v. sol. benzene.

#### DI-PROPYL-ANTHRONE $\text{C}_{20}\text{H}_{18}\text{O}$ i.e.

$\text{C}_6\text{H}_4\langle\text{CO}\text{CPr}_2\rangle\text{C}_6\text{H}_4$ . [124°]. Formed, together with the preceding body, by boiling anthranol (5 g.) with KOH (5 g.), water (25 c.c.), and  $\text{PrI}$  (13 g.) (Hallgarten, B. 22, 1069). Trimetric crystals, sol. hot alcohol.  $\text{CrO}_3$  in  $\text{H}_2\text{OAc}$  oxidises it to anthraquinone.

#### TRI-PROPYL-ARSINE v. vol. i. p. 319.

#### PROPYL-BENZENE v. CUMENE.

**Di-*n*-propyl-benzene**  $\text{C}_6\text{H}_4\text{Pr}_2$  [1:4]. (219°). Formed from *p*-di-bromo-benzene, *n*-propyl bromide, and Na (Körner, B. 11, 1863; A. 216, 223). Formed also, together with the *m*-isomeride, by the action of  $\text{AlCl}_3$  and  $\text{HCl}$  on *n*-cumene (Heise a. Töhl, A. 270, 165). Liquid, volatile with steam. Bromine forms  $\text{C}_6\text{H}_4\text{Br}_2\text{Pr}_2$  [48°].

***n*-iso-Di-propyl-benzene**  $\text{C}_6\text{H}_4\text{PrPr}$  [1:4]. (212° cor.). S.G.  $\frac{2}{3}$  8713. Formed from  $\text{C}_6\text{H}_5\text{Pr}\cdot\text{CH}_2\text{Cl}$  and  $\text{ZnEt}_2$  (Paterno a. Spica, B. 10, 1746) and from  $\text{PrBr}$ , *p*-bromo-cumene, and Na. Formed also, together with the *m*-isomeride, by the action of  $\text{AlCl}_3$  at -2° on a mixture of *n*-cumene and  $\text{PrBr}$  (Heise, B. 24, 772).

***m*-Di-isopropyl-benzene**  $\text{C}_6\text{H}_4\text{Pr}_2$  [1:3]. (204°). Formed, together with the *p*-isomeride, by the action of propyl or isopropyl chloride on benzene in presence of  $\text{AlCl}_3$  (Silva, *Bl.* [2] 43, 320; Uhlhorn, B. 23, 3142) and by the action of  $\text{AlCl}_3$  and  $\text{HCl}$  at 100° on cumene (H. a. T.). Yields isophthalic acid on oxidation.

***p*-Di-isopropyl-benzene**  $\text{C}_6\text{H}_4\text{Pr}_2$  [1:4]. (c. 202°). Formed as above. Yields terephthalic acid on oxidation.

#### PROPYL-BENZENE SULPHONIC ACID v. CUMENE SULPHONIC ACID.

***p*-Di-*n*-propyl-benzene sulphonic acid**  $\text{C}_6\text{H}_4\text{Pr}_2\cdot\text{SO}_3\text{H}$ . [62°]. Formed from di-propyl-benzene and fuming  $\text{H}_2\text{SO}_4$  (Körner, B. 11, 1865; A. 216, 224; Remsen, *Am.* 5, 162). Deliquescent

needles, with pearly lustre.— $\text{NaA}'_2$  4aq.— $\text{KA}'_2$  4aq.— $\text{BaA}'_2$  3aq.— $\text{BaA}'_2$  2aq.— $\text{CaA}'_2$  9aq.— $\text{PbA}'_2$  5aq.

**Amide**  $\text{C}_6\text{H}_4\text{Pr}_2\cdot\text{SO}_2\text{NH}_2$ . [103°]. Hexagonal crystals (from alcohol), sl. sol. hot water.

#### *n*-iso-Di-propyl-benzene sulphonic acid

[1:4: $\infty$ ]  $\text{C}_6\text{H}_4\text{PrPr}\cdot\text{SO}_3\text{H}$ . [60°]. Needles (Heise, B. 24, 771).— $\text{BaA}'_2$  2aq.— $\text{PbA}'_2$  5aq.: minute needles, m. sol. cold water.— $\text{PbA}'_2$  8aq.: needles.

#### Amide. [96°]. Needles.

#### *m*-Di-isopropyl-benzene sulphonic acid

$\text{C}_6\text{H}_4\text{Pr}_2\cdot\text{SO}_3\text{H}$  [1:3: $\infty$ ]. Formed by shaking with  $\text{H}_2\text{SO}_4$  (1½ pts.) the fraction (200°-210°) got by the action of  $\text{AlCl}_3$  on a mixture of  $\text{PrCl}$  and benzene, and separated from the accompanying *p*-di-isopropyl-benzene sulphonic acid by means of its Ba salt (Uhlhorn, B. 23, 3142).— $\text{BaA}'_2$  2aq.: needles, sl. sol. water.— $\text{CuA}'_2$  4½aq.— $\text{MgA}'_2$  4aq.—**Amide**  $\text{C}_6\text{H}_4\text{Pr}_2\cdot\text{SO}_2\text{NH}_2$ . [145°].

#### *p*-Di-isopropyl-benzene sulphonic acid

$\text{C}_6\text{H}_4\text{Pr}_2(\text{SO}_3\text{H})$  [1:4:2]. Formed as above.— $\text{BaA}'_2$ : nodules, v. sol. water.— $\text{CuA}'_2$  6½aq.—**Amide**  $\text{C}_6\text{H}_4\text{Pr}_2\cdot\text{SO}_2\text{NH}_2$ . [102°].

#### *m*-Di-*n*-propyl-benzene disulphonic acid

$\text{C}_6\text{H}_4\text{Pr}_2(\text{SO}_3\text{H})_2$ . Deliquescent tables (Heise).— $\text{K}_2\text{A}''_2$  2aq.— $\text{BaA}''_2$  1½aq.: tables, v. sol. water.— $\text{PbA}''_2$  1½aq.: tables, v. e. sol. warm water.

#### Amide. [195°]. Needles.

#### PROPYL-BENZOIC ACID v. CUMINIC ACID.

#### PROPYL-BENZOYL-ACETIC ACID v. BENZ-

OYL-ACETIC ACID and PHENYL BUTYL KETONE CARBOXYLIC ACID.

#### PROPYL-BENZYL- v. CUMINYL-

***n*-PROPYL BORATE**  $(\text{PrO})_3\text{B}$ . (172°-175°). S.G.  $\frac{12}{15}$  867 (Cahours, C. R. 76, 1383).

#### Isopropyl borate $(\text{PrO})_3\text{B}$ . (140° cor.).

Formed by heating  $\text{B}_2\text{O}_3$  with isopropyl alcohol at 120° (Counciler, *J. pr.* [2] 18, 389). Mobile oil, slowly saponified by water.

***n*-PROPYL BROMIDE**  $\text{PrBr}$ . (71°). S.G.  $\frac{2}{3}$  13835 (Zander, A. 214, 159);  $\frac{2}{3}$  13520 (Brühl, A. 203, 13);  $\frac{1}{10}$  13611;  $\frac{2}{15}$  13474 (Perkin). C.E. (0°-10°) 00123.  $\mu_D = 1.4406$ .  $n_D = 1.3820$ . S.V. 97. M.M. 6:885 at 19-2°. H.F. pr. 30,850. H.F.v. 29,110 (Thomson, *Th.*). Formed from *n*-propyl alcohol and  $\text{HBr}$  (Linnemann, A. 161, 40; Pierre a. Puchot, *J. Ph.* [4] 13, 9). When heated in sealed tubes at 280° it partially changes to isopropyl bromide (Aronstein, *R. T. C.* 1, 134). When heated for a short time with  $\text{AlBr}_3$  it is completely changed to isopropyl bromide (Kekulé a. Schrötter, B. 12, 2279; Gustavson, *J. R.* 15, 61). Bromine forms propylene bromide.— $\text{C}_6\text{H}_5\text{Br}(\text{H}_2\text{S})_2$  23aq (De Forcrand, *A. Ch.* [5] 28, 35).

**Isopropyl bromide**  $\text{PrBr}$ . (60°). S.G.  $\frac{2}{3}$  13397 (Z.);  $\frac{2}{3}$  13097 (B.);  $\frac{1}{10}$  13198;  $\frac{2}{15}$  13052 (Perkin). C.E. (0°-10°) 00127.  $\mu_D = 1.4317$ .  $n_D = 1.3858$  (Brühl). M.M. 7:003 at 17-1°. S.V. 99.

**Formation.**—1. From isopropyl alcohol and  $\text{HBr}$  at 150° (Linnemann, A. 136, 41).—2. From *n*-propyl bromide and  $\text{AlBr}_3$ .—3. From propylene bromide and  $\text{HI}$  (Linnemann, A. 161, 57).

**Preparation.**—By adding bromine (65 g.) gradually to  $\text{PrI}$  (100 g.) in the cold; the yield being 45 g. (R. Meyer, *J. pr.* [2] 34, 105).

#### Properties.—Liquid, not attacked by $\text{Cl}$ .

#### ISOPROPYL-BUTENYL-BENZENE v. BUTENYL-CUMENE.

***n*-PROPYL-ISOBUTYL-AMINE**  $\text{C}_6\text{H}_5\text{N}$  i.e.  $\text{PrNH.C}_4\text{H}_9$ . (124°). Formed by reducing isobutyl-propargyl-amine in alcoholic solution with

sodium (Paul & Heupel, B. 24, 8048).—B'HCl. [185°].—B'H<sub>2</sub>CO<sub>3</sub>. [224°]. Needles.

**ISOPROPYL-BUTYL-AMINE DICARB.**

**OXYLIC ACID** C<sub>4</sub>H<sub>9</sub>NO, i.e. CO<sub>2</sub>H.O.Me.NH.CMe<sub>2</sub>.CH<sub>2</sub>.CO<sub>2</sub>H. A product of the oxidation of triacetoneamine with chromic acid mixture (Heintz, A. 198, 69). Crystalline grains, m. sol. hot water. Yields amido-isobutyric acid when heated.—H<sub>2</sub>A''HCl.—KHA'' 2aq.—Zn(HA'')<sub>2</sub> 6aq.—ZnA'' aq.—CuA'' aq.—AgHA''—AgA''HNO<sub>3</sub> aq: grains.

**PROPYL-ISOBUTYL-GLYOXALINE**

C<sub>10</sub>H<sub>18</sub>N<sub>2</sub>, i.e. CH<sub>3</sub>N:CH.NPr > C.C.H<sub>3</sub>. Oral-propyl-isobutylamine. (241° at 738 mm.). S.G. <sup>12</sup> .915. Formed from isobutyl-glyoxaline and PrIhr (Radziszewski & Szul, B. 17, 1295). Liquid.—B<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub>: minute orange prisms.

**Propyl-butyl-glyoxaline** CH<sub>3</sub>N:CH.NPr > CH<sub>3</sub>N(C<sub>2</sub>H<sub>5</sub>) > (248°) at 728 mm. S.G. <sup>12</sup> .938. Formed from propyl-glyoxaline and butyl iodide. Oxidised by H<sub>2</sub>O<sub>2</sub> to butyl-oxamide [198°] (Rieger, M. 9, 609).—B'HZnCl<sub>2</sub>.—B'H<sub>2</sub>CdCl<sub>2</sub>.—B'H<sub>2</sub>PtCl<sub>4</sub>.

**Propyl-isobutyl-glyoxaline** CH<sub>3</sub>N:CH.NPr > CH<sub>3</sub>N(C<sub>2</sub>H<sub>5</sub>) > (232°) at 736 mm. S.G. <sup>12</sup> .940. Formed from propyl-glyoxaline and isobutyl iodide (Rieger).

**PROPYL ISOBUTYL KETONE** Pr.CO.C<sub>2</sub>H<sub>5</sub>. (155°) at 750 mm. S.G. <sup>2</sup> .831. Formed from isovaleryl chloride and ZnPr<sub>2</sub> (Wagner, J. R. 16, 668). Liquid.

Isopropyl isobutyl ketone Pr.CO.CH<sub>2</sub>Pr. (160°). S.G. <sup>12</sup> .865. Formed by oxidising sec-ethyl alcohol with cold dilute K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and H<sub>2</sub>SO<sub>4</sub> (Williams, C. J. 35, 130). Liquid, not solid at -17°. Does not form a crystalline compound with NaHSO<sub>4</sub>.

**PROPYL-ISOBUTYL-MALONIC ACID** C<sub>4</sub>H<sub>7</sub>CO<sub>2</sub>Pr(CO<sub>2</sub>H)<sub>2</sub>. [129°]. This appears to be the composition of the acid got by saponifying C<sub>4</sub>H<sub>7</sub>C(C<sub>2</sub>H<sub>5</sub>)(CO<sub>2</sub>Et)<sub>2</sub> (249), which is got from malonic ether, isobutyl iodide, allyl iodide, and NaOEt (Ballo, B. 14, 335).

**PROPYL BUTYL OXIDE** Pr.O.C<sub>2</sub>H<sub>5</sub>. (117°). S.G. <sup>2</sup> .7773. C.E. (0°-10°) .00124. S.V. 174.4 (Dobner, A. 243, 7).

**ISOPROPYL-ISOBUTYL-PHOSPHINE** PHPr.CH<sub>2</sub>Pr. (140°). Formed from isopropyl-phosphine and isobutyl iodide at 130° (Hofmann, B. 6, 300).

**ISOPROPYL-ISOBUTYL-QUINOLINE**

C<sub>6</sub>H<sub>5</sub> < CH:CHPr > N=C.C<sub>2</sub>H<sub>5</sub>Pr (296°) at 710 mm. Formed by the action of isovaleric aldehyde and conc. HClAq upon aniline (Spady, B. 17, 1718; 18, 3373).—B'H<sub>2</sub>PtCl<sub>4</sub>. Yellow needles, sl. sol. water.—B'C<sub>2</sub>H<sub>5</sub>(NO<sub>2</sub>)<sub>2</sub>OH. Large yellow plates.—B'HCl aq.—B'HNO<sub>3</sub> aq.—B'H<sub>2</sub>SO<sub>4</sub>.—B'H<sub>2</sub>CrO<sub>4</sub>: orange needles, sol. hot water. *Methyl-iodide* B'MeI aq. Yellow needles, v. sol. alcohol.—B<sub>2</sub>Me<sub>2</sub>PtCl<sub>4</sub>: yellowish-red triclinic prisms.

**PROPYL-TRICARBALLYLIC ACID** CHPr(CO<sub>2</sub>H).CH(CO<sub>2</sub>H).CH<sub>2</sub>.CO<sub>2</sub>H. [152°]. Formed by saponifying its ether, which is made by the action of fumaric ether on sodium propyl-malonic ether (Auwers, B. 24, 311, 2898). Prisms (containing 2aq), v. e. sol. ether.

*Ethyl ether* EtA'' (206° at 16 mm.). S.G. <sup>2</sup> 1.092.

**Isopropyl-tricarballylic acid** CHPr(CO<sub>2</sub>H).CH(CO<sub>2</sub>H).CH<sub>2</sub>.CO<sub>2</sub>H. [162°]. Prepared in like manner from isopropyl-malonic ether. Plates or prisms, v. sl. sol. ligroin.

*Ethyl ether* EtA'' (206° at 20 mm.). S.G. <sup>12</sup> 1.085.

**PROPYL CARBAMATE** NH<sub>2</sub>.CO.OPr. [52°]. (195°). Formed by heating urea with propyl alcohol (Cahours, C. R. 76, 1387). Formed also from Cl.CO<sub>2</sub>Pr and NH<sub>3</sub> (Roemer, B. 6, 1102). Prisms, v. e. sol. water and alcohol.

**Isopropyl carbamate** NH<sub>2</sub>.CO.OPr. [37°]. Formed from Cl.CO<sub>2</sub>Pr and dry NH<sub>3</sub> (Spica & Varda, G. 17, 165). Hygroscopic needles.

**ISOPROPYL-CARBAMINE** Pr.NC. (87°). S.G. <sup>2</sup> .760. Formed from isopropyl iodide and AgCy (Gautier, C. R. 67, 723; A. 149, 155). HClAq forms isopropyl-formamide.

**PROPYL-CARBAMIC ACID** NHPr.CO<sub>2</sub>H.

*Methyl ether* MeA'. (180° at 755 mm.). S.G. <sup>12</sup> .992. Liquid (Thomas, R. T. C. 9, 71). The nitramine NPr(NO<sub>2</sub>).CO.Me. S.G. <sup>12</sup> 1.187 is made from NaAgPr(NO<sub>2</sub>) and Cl.CO<sub>2</sub>Me.

*Ethyl ether* EtA'. (186°). Formed from propylamine and chloro-formic ether (Schreiner, J. pr. [2] 21, 125).

**Isopropyl-carbamic acid** NHPr.CO<sub>2</sub>II.

*Methyl ether* MeA'. (165.5°). S.G. <sup>12</sup> .981. Liquid. The nitramine NPr(NO<sub>2</sub>).CO.Me S.G. <sup>12</sup> 1.159 is also liquid.

**PROPYL-CARBINOL v. BUTYL ALCOHOL.**

**DI-PROPYL-CARBINOL v. HEPTYL ALCOHOL.**

**DI-PROPYL-CARBONBENZONIC ACIDS**

C<sub>6</sub>H<sub>5</sub>.O<sub>2</sub>. Two acids of this formula [139°] and [90°] are formed by heating phenyl benzyl ketone with n-propyl alcohol and KOH (Zagumenny, A. 184, 166). The acid [139°] forms a di-nitro-derivative with NaHSO<sub>4</sub>.

**PROPYL CARBONATE** CO(OPr)<sub>2</sub>. (168° cor.). S.G. <sup>12</sup> .949 (Roese, A. 205, 230).

**Propyl orthocarbonate** C(OPr)<sub>3</sub>. (224° cor.). S.G. <sup>2</sup> .911. Formed from NaOPr and chloropicrin (Roese, A. 205, 253).

**n-PROPYL CHLORIDE** PrCl. Mol. w. 78<sup>1</sup>. (46° i.v.). S.G. <sup>2</sup> .9123 (Zander, A. 214, 156); <sup>20</sup> .8898 (Brühl, A. 200, 179); <sup>17</sup> .8930; <sup>25</sup> .8813 (Perkin). M.M. 5.056 at 16°. μ<sub>D</sub> = 1.3934. R<sub>∞</sub> = 33.36. S.V. 91.6. H.F.p. 37.760. H.F.v. 36.020. C.E. (0°-10°) .00137. Formed by the action of chlorine on propane and on PrI. Prepared by saturating n-propyl alcohol with gaseous HCl, and heating at 125° with conc. HClAq (Malbot, B. [3] 2, 136; cf. Pierre & Puchot, A. Ch. [4] 20, 234). Acts with extreme slowness on alcoholic NH<sub>3</sub> (Vincent, B. [2] 45, 504). Not changed to PrCl by heating in sealed tubes (Aronstein, R. T. C. 1, 134).—PrCl(H<sub>2</sub>S)<sub>2</sub> 23aq (De Forcrand, A. Ch. [5] 28, 34).

**Isopropyl chloride** PrCl. (36°). S.G. <sup>2</sup> .8925 (Z.); <sup>15</sup> .8688; <sup>25</sup> .8575 (P.). M.M. 5.159 at 17.2°. S.V. 94. C.E. (0°-10°) .00142. Formed from isopropyl alcohol and HCl. Chlorine converts it into CH<sub>3</sub>.CCl<sub>2</sub>.CH<sub>3</sub> and CH<sub>3</sub>.CHCl.CH<sub>2</sub>Cl. Partially converted into NH<sub>2</sub>Pr by heating with conc. NH<sub>3</sub>Aq at 140° (Malbot, C. R. 111, 660).

**ISOPROPYL CINNAMIC ACID v. CUMYL-ACRYLIC ACID.**

*References.*—AMIDO-, CHLORO-, and NITRO-PROPYL-CINNAMIC ACIDS.

**PROPYL-m-CRESOL** C<sub>6</sub>H<sub>4</sub>MePr.OH. (230°-235° at 734 mm.). Formed, together with its

propyl ether and di-propyl-*m*-cresol, by heating *m*-cresol with propyl alcohol and  $MgCl_2$  (Mazzara, *G.* 12, 187, 332). Liquid, sl. sol. water, sol. alcohol and ether. Not solid at  $-15^\circ$ . Not coloured by  $FeCl_3$ . Yields a crystalline nitroso-derivative  $[140^\circ]$ .

*Methyl ether* MeA'. ( $226^\circ$ ) at 740 mm.

*Propyl ether* PrA'. ( $235^\circ$ ,  $240^\circ$ ).

*Acetyl derivative* AcA'. ( $240^\circ$ ) at 743 mm.

Isopropyl-*m*-cresol  $C_6H_4PrMe.OH$ . ( $238^\circ$ ). Formed in like manner by heating *m*-cresol with isopropyl alcohol and  $MgCl_2$  (Mazzara, *G.* 12, 505). Oil. Yields  $C_6H_4(NO)PrMe.OH$   $[167^\circ]$ .

*Methyl ether* MeA'. ( $215^\circ$ - $220^\circ$ ).

*Isopropyl ether* PrA'. ( $230^\circ$ - $235^\circ$ ).

Isomeride *v.* THYMOL.

Propyl-*o*-cresol *v.* CARVACROL and CYMENOL.

Isopropyl-cresol  $C_6H_4PrMe.OH$ . ( $229^\circ$  cor.). S.G.  $\rho$  1.0012. Formed by potash-fusion from the *m*-isocymene derived from camphor (Spica, *G.* 12, 552). Not coloured by  $FeCl_3$ .

*Ethyl ether* EtA'. ( $228^\circ$  cor.).

Di-propyl-*m*-cresol  $C_6H_4Pr_2Me.OH$ . ( $250^\circ$ ). Formed as above. Liquid, yielding a liquid acetyl derivative ( $255^\circ$ - $260^\circ$ ).

Di-isopropyl-*m*-cresol  $C_6H_4Pr_2Me(OH)$ . ( $251^\circ$ ). Formed at the same time as isopropyl-*m*-cresol (M.). Liquid smelling like phenol, sl. sol. water, insol. dilute potash.

*Methyl ether* MeA'. ( $243^\circ$ ).

*Acetyl derivative* AcA'. ( $255^\circ$ - $260^\circ$ ).

ISOPROPYL-CUMIDINE  $C_6H_4Pr.NHPr$ . ( $245^\circ$ - $250^\circ$ ). A product of the action of aniline and  $ZnCl_2$  on isopropyl alcohol (Louis, *B.* 16, 111). Liquid. Forms a granular picrate.

ISOPROPYL CYANATE *v.* vol. ii. p. 315.

PROPYL CYANIDE *v.* Nitrile of BUTYRIC ACID.

PROPYLENE  $C_3H_6$ . Mol. w. 42. S.  $-44$  at  $0^\circ$ ;  $-22$  at  $20^\circ$  (von Than, *A.* 123, 137). S. (alcohol) 13. S. ( $H_2SO_4$ ) 200 (Berthelot). H.F.p. 3,220. H.F.v. 2,060 (Thomsen, *Th.*).

*Formation*.—1. By passing fusel oil, valeric acid, or light petroleum through a red-hot tube (J. W. Reynolds, *A.* 77, 118; Prunier, *J.* 1873, 347).—2. By distilling calcium oxalate with KOAc (Dusart, *A.* 97, 127).—3. By the action of mercury (containing a trace of zinc) and fuming  $HClAq$  on allyl iodide (Berthelot, *A. De Luca*, *A.* 92, 306).—4. Mixed with  $H$  ( $\frac{1}{2}$  vol.), by reducing allyl iodide in alcoholic solution with granulated zinc and  $HClAq$  (Tollens & Henninger, *A.* 156, 156).—5. From allyl iodide and  $HI$  (Butlerov, *A.* 145, 271).—6. A product of the action of  $ZnEt_2$  on  $CCl_4$  (Rieth & Beilstein, *A.* 124, 242) on allyl iodide (Wurtz, *Bl.* 5, 61) and on  $CHBr_3$  (Beilstein, *Bl.* [2] 2, 51).—7. By boiling *n*- or iso-propyl iodide with alcoholic potash (Freund, *M.* 8, 683; Erlenmeyer, *A.* 139, 228).—8. Together with other hydrocarbons, by treating propylene bromide with water and sodium-amalgam or with zinc and  $HClAq$  (Prunier, *C. R.* 76, 98).—9. By heating  $CCl_3Me_2$  or  $CBr_3Me_2$  with Na at  $140^\circ$  (Friedel & Ladenburg, *Z.* 1868, 48; Reboul, *A. Ch.* [5] 14, 488).—10. Together with cresol, by heating thymol with  $P_2O_5$  (Engelhardt & Latschinoff, *Z.* 1869, 616).—11. In the manufacture of oil-gas (Armstrong, *C. J.* 49, 74).—12. Together with ethylene, by heating allyl alcohol with  $P_2O_5$  (Béhal, *A. Ch.* [6] 18, 860).—

13. By heating  $N(C_2H_5)_3$  with  $C_2H_5Cl$  at  $190^\circ$  (Malbot, *A. Ch.* [6] 13, 546).

*Preparation*.—1. By dropping propyl alcohol on strongly-heated  $ZnCl_2$  (Le Bel & Guesne, *Am.* 2, 23).—2. By passing gaseous  $HI$  into allyl iodide,  $PrI$  being also formed (Malbot, *C. R.* 107, 114; *Bl.* [2] 50, 449).—3. By pouring an alcoholic solution of allyl iodide on zinc (Gladstone & Tribe, *B.* 6, 1550; Niederist, *A.* 196, 358).—4. By dropping propyl alcohol (4 pts.) on  $P_2O_5$  (3 pts.) (Beilstein, *B.* 15, 1498).—5. By mixing isopropyl alcohol (200 g.) with  $ZnCl_2$  (650 g.) and heating after twenty-four hours (Friedel & Silva, *J.* 1873, 322).

*Properties*.—Colourless gas, liquefied by a pressure of eight atmospheres (Moltischanoftsky, *J. R.* 21, 31). Unites with  $Cl$  and  $Br$ . Its solution in  $H_2SO_4$  yields isopropyl alcohol on distilling with water. Cuprous chloride in  $HClAq$  absorbs it somewhat.  $HClAq$  heated with propylene for seventy hours at  $100^\circ$  forms isopropyl chloride (Berthelot, *A.* 104, 184);  $HBr$  and  $HI$  act in like manner. Dilute  $CrO_3$  forms acetic acid and  $CO_2$  (Berthelot, *A.* 150, 373). Alkaline  $KMnO_4$  forms formic and acetic acids (Truchot, *C. R.* 63, 274).  $KCl$  added to a solution of propylene in  $PtCl_2$  and  $HClAq$  ppt.  $C_3H_7PtCl_2KCl$  aq (Birnbau, *A.* 145, 72).

Di-propylene *v.* HEXYLENE.

*References*.—BROMO-, DI-BROMO- IODO-, CHLORO-, CHLORO- IODO-, DI-CHLORO-NITRO-, and IODO- PROPYLENE.

PROPYLENE-ACETOACETIC ACID *v.* ACETOACETIC ACID and METHYL TRIMETHYLENYLMETHYL KETONE CARBOXYLIC ACID.

PROPYLENE-ALLYL- $\psi$ -THIO-UREA

$CHMe-S$   
 $CH_2-N(C_2H_5)>C.NH$ . Formed from propylene- $\psi$ -thio-urea and allyl iodide (Hirsch, *B.* 23, 973). Oil.— $B'C_2H_4N_2O_2$ . [ $126^\circ$ ]. Triangular prisms.

Isomeride  $CHMe.S$   
 $CH_2.NH$  $>C.NC_2H_5$ . [ $56^\circ$ ]. Got from  $\beta$ -bromo-propyl-amine and mustard oil. Prisms (from ligroin).— $B'C_2H_4N_2O_2$ . [ $130^\circ$ ].— $B'C_2H_4NCS$ . [ $52^\circ$ ]. White prisms.

PROPYLENE-DIAMINE  $C_3H_6N_2$ , *i.e.*  $CH_3CH(NH_2)CH_2NH_2$ . ( $119^\circ$ ). S.G.  $\rho$  878. Formed by heating propylene bromide with alcoholic ammonia at  $10J^\circ$ - $150^\circ$  (Hofmann, *B.* 6, 308; Strache, *B.* 21, 2358). Hygroscopic liquid, fuming in the air. Yields a hydrate  $(C_3H_6N_2)_2.aq$ , boiling at the same temperature as the base, and dehydrated by Na. Benzoic aldehyde forms oily  $C_3H_6(N:CHPh)_2$ , decomposed by  $HCl$  into the parent substances. Acetoacetic ether forms oily  $C_3H_6(NH.CMe.CH.CO.Et)_2$ .

Salts.— $B'H_2Cl_2$ . [ $220^\circ$ ]. Very hygroscopic needles.— $B'H_2PtCl_6$ . Small four-sided tables.

*Acetyl derivative*  $C_3H_6(NHAc)_2$ . [ $139^\circ$ ].

Needles, *v.* e. sol. water and alcohol.

*Benzoyl derivative*  $C_3H_6N_2$ . [ $198^\circ$ ].

PROPYLENE-AMYL- $\psi$ -THIO-UREA

$CHMe.S$   
 $CH_2-N$  $>C.NHC_4H_9$ . [ $32^\circ$ ]. ( $267^\circ$ ). Formed by heating allyl-amythio-urea with conc.  $HClAq$  at  $100^\circ$  (Avenarius, *B.* 24, 264).

PROPYLENE BROMIDE *v.* DI-BROMO-PROPANE.

PROPYLENE TRICARBOXYLIC ACID.

*Ethyl ether*  $CO_2Et.CH:CH.CH(CO_2Et)_2$ . ( $171^\circ$

## PROPYLENE SULPHOCYANIDE.

at 15 mm.). Formed by the action of water or of NaOHAq upon  $\text{CH}_2\text{C}(\text{CO}_2\text{Et})\text{C}(\text{OEt})\text{CO} \rightarrow \text{O}$  [94°], which is got by distilling di-carboxy-glutaconic ether *in vacuo* (Guthzeit & Drossel, B. 22, 1425). It is identical with iso-acetic ether.

Isomeride v. ACONITIC ACID.

Propylene tetra-carboxylic acid  $(\text{CO}_2\text{H})_2\text{CH}_2\text{C}(\text{CO}_2\text{H})_2\text{CH}_2\text{CO}_2\text{H}$ . [192°]. Got by saponifying its ether. Colourless crystals (containing 2aq). Gives off  $\text{CO}_2$  at 180°.

Salts. —  $\text{Na}_2\text{HA}^{iv}$  8aq. —  $\text{Ba}_2\text{A}^{iv}$  1½aq. —  $\text{Ca}_2\text{A}^{iv}$  3½aq.

Ethyl ether  $\text{Et}_2\text{A}^{iv}$ . (230°–230° at 40 mm.). Formed from sodium-maleic ether and bromo-maleic ether (Schacherl, A. 229, 91).

Isomerides. — DICARBOXY-GLUTAONIC ACID and TRIMETHYLENE TETRACARBOXYLIC ACID.

PROPYLENE CHLORHYDRIN v. CHLORO-PROPYL ALCOHOL.

PROPYLENE CHLORIDE v. DICHLORO-PROPANE.

PROPYLENE CHLOROBROMIDE v. CHLORO-BROMO-PROPANE.

PROPYLENE GLYCOL  $\text{C}_3\text{H}_8\text{O}_2$ , i.e.  $\text{C}_3\text{H}_7(\text{OH})_2$ . Di-oxy-propane. Mol. w. 76. (189°). S.G.  $\frac{4}{5}$  1.0527 (Z.). C.E. (0°–10°) .00069. S. (other) 11. S.V. 85.2 (Zander, A. 214, 177).

Formation. — 1. By saponifying its acetyl-derivative (Wurtz, A. Ch. [3] 55, 438). — 2. By reduction of  $\text{CH}_3\text{CH}(\text{OH})\text{CH}_2\text{OH}$  by sodium-amalgam (Lourenço, C. R. 53, 1043). — 3. By heating propylene bromide with PbO and much water at 150° (Eltekoff, J. R. 10, 210). — 4. By boiling propylene bromide with aqueous  $\text{K}_2\text{CO}_3$  for some days (Lartmann, J. pr. [2] 16, 383). — 5. By boiling propylene bromide (1 pt.) with water (36 pts.), the yield being 43 p.c. (Niederist, A. 196, 359). — 6. By the action of the copper-zinc couple and some HClAq on the product of the action of  $\text{AcBr}$  on glycerin (Hanriot, C. R. 86, 1139). — 7. By treating allyl alcohol with dilute  $\text{H}_2\text{SO}_4$  (20 p.c.) or  $\text{HCl}$  (10 p.c.) (Solonina, Bl. [2] 46, 816).

Preparation. — Glycerin (1,300 g.) is distilled with NaOH (550 g.) and the aqueous layer concentrated and distilled; the yield is 140 g. (Belchoubek, B. 12, 1872; Morley & Green, C. J. 47, 182).

Properties. — Liquid, with sweet taste; miscible with water and alcohol.

Reactions. — 1. Water containing a trace of  $\text{HCl}$  forms propionic aldehyde at 215° (Linne-mann, A. 192, 61). It also yields propionic aldehyde on heating with  $\text{ZnCl}_2$  (Flavitzky, B. 11, 1256). — 2. Conc.  $\text{HIAq}$  forms isopropyl iodide (Wurtz, A. Suppl. 1, 381). — 3.  $\text{PCl}_5$  forms di-chloro-propane. — 4.  $\text{KOH}$  at 250° forms oxalic acid and  $\text{H}_2$ . — 5. Chromic acid mixture forms acetic acid (Flavitzky, B. 11, 1256). — 6. Oxidised by platinum black and air to lactic acid. — 7. Glyceryl trimetric forms, at 100°, oily  $\text{CH}_2\text{CH}(\text{O.NO})\text{CH}_2\text{O.NO}$  (109°), S.G.  $\frac{4}{5}$  1.44, which explodes in sunlight (Bertoni, C. C. 1887, 85).

Acetyl derivative  $\text{C}_3\text{H}_7\text{O}_2$ , i.e.  $\text{C}_3\text{H}_7(\text{OAc})_2$ . Propylene acetate. (186°). S.G.  $\frac{4}{5}$  1.109. S. 11. Formed by heating  $\text{C}_3\text{H}_7\text{Br}_2$  with  $\text{AgOAc}$  and  $\text{HOAc}$  (Wurtz, A. 105, 202). Neutral liquid.

Mono-benzoyl derivative  $\text{CH}_2\text{CH}(\text{OBz})\text{CH}_2\text{OH}$ . Formed from the amine  $\text{CH}_2\text{CH}(\text{OBz})\text{CH}_2\text{NH}_2$  and  $\text{HNO}_3$  (Gabriel & Heymann, B. 23, 2501). Oil.

Di-benzoyl derivative  $\text{CH}_2\text{CH}(\text{OBz})_2\text{CH}_2\text{OBz}$ . (240° at 13 mm.). Liquid (Friedel & Silva, C. R. 78, 1879).

Di-nitrate  $\text{C}_3\text{H}_7(\text{O.NO}_2)_2$ . S.G.  $\frac{4}{5}$  1.335. Formed by dropping propylene oxide into strongly-cooled fuming  $\text{HNO}_3$  (Henry, A. Ch. [4] 27, 261). Oil.

Chlorhydrin v. CHLORO-PROPYL ALCOHOL.

Bromhydrin v. BROMO-PROPYL ALCOHOL.

Iodhydrin  $\text{C}_3\text{H}_7\text{I}(\text{OH})_2$ . (105° at 60 mm.). Formed from propylene oxide and  $\text{HI}$  (Markownikoff, Z. 1870, 423). Liquid.

Active propylene glycol  $\text{C}_3\text{H}_7(\text{OH})_2$ .  $\alpha_D = -4^\circ 35'$  to  $-1^\circ 15'$  in a 22 mm. tube. Formed, together with propionic and lactic acids, by allowing *Bacterium termo* to breed in ordinary inactive propylene glycol (Le Bel, C. R. 92, 532). Yields active propylene oxide (35°)  $\alpha_D = +1^\circ 10'$  in a 22 mm. tube.

n-Propylene glycol v. TRI-METHYLENE GLYCOL.

PROPYLENE IODIDE v. DI-iodo-PROPANE.

PROPYLENE MERCAPTAN  $\text{C}_3\text{H}_7(\text{SH})_2$ . (152° *in vacuo*). Formed by reducing propylene sulphocyanide with  $\text{Zn}$  and  $\text{HClAq}$  (Hagelberg, B. 23, 1087).

PROPYLENE OXIDE  $\text{C}_3\text{H}_6\text{O}$  i.e.

$\text{CHMe} \rightarrow \text{O}$ . Mol. w. 58. (35°). S.G.  $\frac{4}{5}$  .859.

$\text{CH}_2 \rightarrow \text{O}$ . V.D. 2.0. Formed by warming propylene chloro-hydrin with  $\text{KOHAq}$  (Oser, Bl. 1860, 237; Morley, B. 15, 179). Dried over  $\text{KOH}$ . Neutral liquid, smelling like acetone. Miscible with water, alcohol, and ether. Reduced by sodium-amalgam to isopropyl alcohol. Yields acetic acid when oxidised by moist  $\text{Ag}_2\text{O}$  (Linnemann, M. 6, 869).

PROPYLENE-OXIDE CARBOXYLIC ACID v. METHYL-GLYCINOIC ACID.

PROPYLENE PHENYL ETHYL KETATE

$\text{CHMe.O} \rightarrow \text{CPhEt}$ . (235° cor.). S.G.  $\frac{4}{5}$  .988.

Formed by dropping  $\text{C}_3\text{H}_7\text{Cl.OBz}$  into a mixture of  $\text{ZnEt}_2$  and toluene, and then adding water (Morley & Green, C. J. 47, 134; B. 17, 8015). Oil, with pleasant odour; sol. ether. Not attacked by alcoholic potash, by  $\text{AcCl}$ , by  $\text{Na}$ , by hydroxylamine, by phenyl-hydrazine, or by  $\text{HClAq}$  at 155°.  $\text{HI}$  at 200° yields  $\text{PI}$  and phenyl ethyl ketone. By dissolving in  $\text{H}_2\text{SO}_4$  and pouring into water, it is split up into propylene glycol and  $\text{C}_3\text{H}_7\text{CO}_2\text{C}_2\text{H}_5$ . Nitric acid oxidises it to acetic and benzoic acids. Bromine forms a mono-bromo-derivative (230°).

PROPYLENE - PROPYL -  $\psi$  - THIO - UREA

$\text{CHMe.S} \rightarrow \text{C.NHPr}$ . [237°]. Formed by heating allyl-propyl-thio-urea with conc.  $\text{HClAq}$  at 100° (Avenarius, B. 24, 264). Oil.—Pierate [138°].

PROPYLENE SULPHIDE  $\text{C}_3\text{H}_6\text{S}$ . Formed from  $\text{C}_3\text{H}_7\text{Br}_2$  and alcoholic  $\text{Na}_2\text{S}$  (Husemann, A. 126, 296). Amorphous powder.

PROPYLENE SULPHOCYANIDE  $\text{C}_3\text{H}_7\text{N}_2\text{S}$ , i.e.  $\text{CH}_2\text{CH}(\text{SCy})\text{CH}_2\text{SCy}$ . Formed by heating  $\text{C}_3\text{H}_7\text{Br}_2$  with potassium sulphocyanide and alcohol at 100° (Hagelberg, B. 23, 1086). Insol. water, sol. alcohol and ether.

**PROPYLENE DISULPHONIC ACID** *v.* **PROPANE DISULPHONIC ACID.****PROPYLENE SULPHONIC ACID**

$\text{CH}_3\text{CH}_2\text{CH}_2\text{SO}_3\text{H}$ . Formed by boiling allyl iodide with conc.  $\text{K}_2\text{SO}_4$  (Von Rad, A. 161, 218).— $\text{KA}'$ . Crystalline solid.— $(\text{KA}')$ ,  $\text{K}_2\text{I}_2$ .— $(\text{KA}')$ ,  $\text{K}_2\text{I}_2$ . White solid.

**PROPYLENE TRI-THIO-CARBONATE**

$\text{C}_3\text{H}_7\text{OS}_3$ . S.G.  $2^0$  1.81. Formed from  $\text{C}_3\text{H}_7\text{Br}$  and  $\text{Na}_2\text{CS}_3$  (Husemann, A. 126, 269). Thick liquid, of disagreeable smell.

**PROPYLENE- $\psi$ -THIO-UREA**  $\text{C}_3\text{H}_7\text{N}_2\text{S}$  *i.e.*

$\text{CHMe.S} > \text{C:NH}$ . *Imido-methyl-thiazole tetrahydride*. Formed by heating allyl-thio-urea with  $\text{HClAq}$  (S.G. 1.17) under pressure at  $100^0$  (Gabriel, B. 22, 2985). Formed also from  $\beta$ -bromo-propyl-amine hydrobromide and potassium sulphocyanide (Hirsch, B. 23, 965). Liquid.— $\text{B}'\text{H}_2\text{PtCl}_6$ . [ $212^0$ ].— $\text{B}'\text{HAuCl}_4$ .— $\text{B}'\text{C}_6\text{H}_5\text{N}_3\text{O}_2$ . [ $200^0$ ].—*Methylo-iodide* [ $172^0$ ]. Colourless prisms.

**PROPYLENE  $\psi$ -UREA**  $\text{CHMe.O} > \text{C:NH}$ .

Formed by heating allyl-urea with  $\text{HClAq}$  at  $100^0$  (Gabriel, B. 22, 2990), and by heating  $\beta$ -bromo-propyl-amine hydrobromide with potassium cyanate at  $100^0$  (Hirsch, B. 23, 966).— $\text{B}'\text{C}_6\text{H}_5\text{N}_3\text{O}_2$ . [ $186^0$ ]. Needles.— $\text{B}'\text{H}_2\text{PtCl}_6$ .

**PROPYL ETHER** *v.* **DI-PROPYL OXIDE.****PROPYL-ETHYLENE** *v.* **AMYLENE.****PROPYL-EUGENOL** *v.* **EUGENOL.**

**PROPYL FLUORIDE**  $\text{PrF}$ . ( $2^0$ ). V.D. 2.161 at  $20^0$  (calc. 2.175). S. 1 at  $15^0$ . Formed by gently warming  $\text{AgF}$  with  $\text{PrI}$  (Meslans, C. R. 108, 352). Gas, with ethereal odour and hot, sweet taste. Has no action on glass when dry. V. sol. alcohol, ether, and benzene.

Isopropyl fluoride  $\text{PrF}$ . ( $-5^0$ ). S. 1.5 at  $15^0$ . S. (alcohol) 29 at  $16^0$ . V.D. 2.171. Formed from  $\text{AgF}$  and  $\text{PrI}$ . Gas, not affected by  $\text{KOHAc}$  at  $100^0$ . Br at  $30^0$  forms a liquid ( $143^0$ ), while chlorine forms a liquid ( $105^0$ ).

**ISOPROPYL-FORMAMIDE** *v.* *Formamide* in article on **FORMIC ACID**.

**DI-PROPYL-FURFURANE**  $\text{C}_6\text{H}_{10}\text{Pr}_2\text{O}$ . ( $120^0$ ). One of the products of the distillation of sodium citrate with lime (Bischoff, B. 23, 1918).

**DI-PROPYL-GLUTARIC ACID**  $\text{C}_6\text{H}_{10}\text{O}_4$  *i.e.*  $(\text{CO}_2\text{H.CH.Pr})_2\text{CH}_2$ . ( $89^0$ ). Formed by heating  $(\text{CO}_2\text{H})_2\text{CPr.CH}_2$  above  $170^0$  (Dressel, A. 250, 190). Needles, v. sl. sol. water, v. sol. ether.

**PROPYL-GLYCOL** *v.* **PROPYLENE GLYCOL.****PROPYL-GLYOXAL** *Mono-oxim.*

$\text{C}_3\text{H}_7\text{CO.CH:NOH}$ . [ $51^0$ ]. Formed from methyl propyl ketone, amyl nitrite, and  $\text{HCl}$  or  $\text{NaOEt}$  (Claisen a. Manasse, B. 22, 528). Pearly plates.

*Di-oxim*  $\text{Pr.C(NO)H.CH(NO)H}$ . [ $168^0$ ].*Di-phenyl-di-hydrate*

$\text{PrC(N.HPh).CH(N.HPh)}$ . [ $163^0$ ]. Needles.

**PROPYL-GLYOXALINE**  $\text{C}_3\text{H}_7\text{N}_2$ . ( $219^0$ — $228^0$ ). S.G.  $12^0$  2.67. Formed by heating glyoxaline with  $\text{PrBr}$  (Wallach, B. 15, 650; 16, 534; A. 214, 321). Liquid, miscible with water.  $\text{HgCl}_2$  added to its aqueous solution gives a pp. sol.  $\text{HClAq}$ .— $\text{B}'\text{H}_2\text{PtCl}_6$ . Crystals, sol. hot water.

**Propyl-glyoxaline**  $\text{CH.N} > \text{CPr}$ . ( $267^0$ ).

Formed from glyoxal, *n*-butyric aldehyde and  $\text{NH}_3$  (Rieger, M. 9, 603). Oil.— $\text{B}'\text{H}_2\text{C}_2\text{O}_6$ .

[ $192^0$ ].— $\text{B}'\text{H}_2\text{C}_2\text{O}_6$ , 2aq. [ $161^0$ ]; plates or needles.— $\text{B}'\text{H}_2\text{PtCl}_6$ : yellow prisms.

**Isopropyl-glyoxaline** *Glyoxal-isobutyline*.

[ $129^0$ ]. (c.  $250^0$ ). Formed from glyoxal and isobutyric aldehyde-ammonia (Radziszewski, B. 16, 747). Needles, sol. alcohol, benzene, and hot water.— $\text{B}'\text{HCl}$ . [ $105^0$ ] (Rieger).— $\text{B}'\text{HBr}$ . [ $222^0$ ].— $\text{B}'\text{H}_2\text{C}_2\text{O}_6$ . [ $195^0$ ].

**Di-propyl-glyoxaline**  $\text{C}_6\text{H}_{10}\text{Pr}_2$ . ( $227^0$ ). S.G.  $12^0$  2.939. Formed by heating propyl-glyoxaline with  $\text{PrI}$  (Rieger, M. 9, 607).

***n*-PROPYL-GLYOXYLIC ACID**  $\text{Pr.CO.CO}_2\text{H}$ . ( $180^0$ — $185^0$ ) at 760 mm.; ( $115^0$ ) at 84 mm. Got by the action of  $\text{HCl}$  on the nitrile ( $133^0$ — $137^0$ ) which is made from  $\text{AgCy}$  and butyryl chloride (E. Moritz, C. J. 39, 16). Liquid.

*Amide*  $\text{C}_3\text{H}_7\text{O.CONH}_2$ . [ $106^0$ ]. Formed from the nitrile and conc.  $\text{HClAq}$ .

*Oxim*  $\text{PrC(NO)H.CO}_2\text{H}$ . [ $144^0$ ]. Formed by the action of alcoholic soda and  $\text{NaNO}_2$  on propyl-acetoacetic ether (Fürth, B. 16, 2180). Small needles, v. sol. alcohol, sl. sol. water.

**Isopropyl-glyoxylic acid**  $\text{*Pr.CO.CO}_2\text{H}$ . A mixture ( $93^0$  at 45 mm.) of this acid with isobutyric acid is got by the action of  $\text{HCl}$  on diisobutyryl dicyanide (Moritz, C. J. 39, 14).

*Amide*  $\text{*Pr.CO.CONH}_2$ . [ $126^0$ ].

**PROPYL HEPTYL KETONE**  $\text{C}_7\text{H}_{15}\text{Pr.CO.C}_3\text{H}_7$ . [ $12^0$ ]. ( $222^0$ ). S.G.  $22^0$  2.828. Formed by distilling calcium butyrate (Jämprecht, A. 108, 185).

**PROPYL HEPTYLOXIDE**  $\text{PrOC}_7\text{H}_{15}$ . ( $188^0$ ). S.G.  $3^0$  7.987. S.V. 245.6. C.E. ( $0^0$ — $10^0$ ) 0.0099 (Dobriner, A. 243, 7).

**DI-ISO-PROPYL-HEXINYL DIKETONE**  $\text{Pr.CO.C}_6\text{H}_{13}\text{C}_6\text{H}_{13}\text{CO.Pr}$ . *Di-isobutyrylone*. (c.  $266^0$ ). Formed by the action of sodium on isobutyric ether (Bruggemann, A. 246, 151).

**PROPYL-HEXYL-CARBINOL** *v.* **DECTYL ALCOHOL.**

**PROPYL-HEXYL-GLYOXALINE**  $\text{C}_7\text{H}_{13}\text{PrN}_2$ . *Oxalpropylenanthylone*. ( $286^0$ ). S.G.  $12^0$  2.919. Formed from hexyl-glyoxaline and  $\text{PrBr}$  (Karez, M. 8, 222). Oil.

**PROPYL HEXYL KETONE**  $\text{Pr.CO.C}_6\text{H}_{13}$ . [ $-9.5^0$ ]. ( $207^0$ ). S.G.  $21^0$  2.824. Formed by oxidation of the corresponding alcohol (Wagner, J. pr. [2] 44, 271). Needles. Oxidised by  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  to heptic and propionic acids.

Isopropyl hexyl ketone  $\text{Pr.CO.C}_6\text{H}_{13}$ . ( $200^0$ — $210^0$ ). S.G.  $12^0$  2.841. Formed by distilling calcium isobutyrate with calcium heptate (Fuchs, J. R. 7, 334). Yields acetone,  $\text{HOAc}$ , and heptic acid on oxidation.

**PROPYL HYPOPHOSPHATE**  $\text{Pr}_3\text{P}_2\text{O}_5$ . S.G.  $12^0$  1.134. Formed from  $\text{Ag}_3\text{P}_2\text{O}_5$  and  $\text{PrI}$  (twice the calculated quantity) at  $120^0$  (Sänger, A. 232, 12). Oil. Decomposed by hot water.

Propyl-hypophosphate of barium

$\text{PrBaHP}_2\text{O}_5$ . Gaa. Needles.

**PROPYLIDENE-ACETIC ACID** *v.* **PENTENOIC ACID.****ISOPROPYLIDENE-AMIDO-PHENOL**

$\text{CMe}_2\text{N.C}_6\text{H}_4\text{OH}$ . [ $158^0$ ]. Formed from *p*-amido-phenol, acetone, and  $\text{HOAc}$  (Haegle, B. 25, 2755). Colourless plates.

**ISO-PROPYLIDENE-ANILINE**  $\text{C}_6\text{H}_5\text{N:CM}_2$ . ( $228^0$ ). V.D. 66.4 (calc. 66.5). From acetone and aniline in presence of dehydrating agents (Engler a. Heine, B. 6, 638; Riehm, A. 238, 10). Liquid; rapidly turning brown in air. Its salts

PROPYL-MALONIC ACID  $C_5H_8O_4$  *iso.*  
CHPr(CO<sub>2</sub>H) Mol. w. 146. [84°] (S.); [96°]

(F.). H.C.p. 675,000. H.C.v. 674,700. H.F. 234,000 (Stohmann, *J. pr.* [2] 40, 211).

*Ethyl ether Et.A.* (222°) (Fürth, M. 9, 809). S.G.  $\frac{1}{15}$  .9931;  $\frac{25}{15}$  .9854. M.M. 10-367 at 18° (Perkin, C. J. 45, 514). Formed from malonic ether, PrI, and zinc or NaOEt.

Isopropyl-malonic acid  $\text{CPrH}(\text{CO}_2\text{H})_2$ . [87°]. H.C.v. 674,900. H.C.p. 675,200. H.F. 233,800 (Stohmann). Formed by saponifying its ether, which is made from sodium-malonic ether and PrI (Conrad a. Bischoff, B. 13, 595; A. 204, 144). Prisms, sol. water, alcohol, and ether. Yields iso-valeric acid at 180°. —AgA'.

*Ethyl ether Et.A.* (214°). S.G.  $\frac{20}{15}$  .997 (C. a. B.);  $\frac{15}{15}$  .9927;  $\frac{25}{15}$  .9852 (Perkin). M.M. 10-482 at 17°.

References.—DI-BROMO- and OXY-PROPYL-MALONIC ACID.

ISOPROPYL-MALONIC ALDEHYDE NI-TRILE  $\text{PrCH}(\text{CN})\text{CHO}$ . (137°). V.D. 3-83 (calc. 3-87). S.G.  $\frac{15}{15}$  .911. Formed by heating iodo-isovaleric aldehyde with KCy or AgCy (Chautard, A. Ch. [6] 16, 188). Oil which reduces Fehling's solution. Miscible with alcohol and ether.

n-PROPYL MERCAPTAN  $\text{PrSH}$ . Mol. w. 76. (68°) (Roemer, B. 6, 784; Schatzmann, A. 261, 7). Formed from PrBr and alcoholic KSH. Oil, smelling like mercaptan.  $\text{Hg}(\text{SlPr})_2$ .

Isopropyl mercaptan  $\text{PrSH}$ . (57°-60°) (Henry, B. 2, 435; Claus, B. 6, 659; 8, 532). Formed from PrI and alcoholic KSH.  $\text{Hg}(\text{SlPr})_2$ : white plates (from alcohol).

PROPYL-METHANE is BUTANE.

Di-propyl-methane v. HEPTANE.

DI-PROPYL-TRIMETHYLENE TRISUL-PHONE  $\text{CPr}_2\text{SO}_2\text{CH}_2\text{SO}_2\text{CH}_2\text{SO}_2\text{CPr}_2$ . [297°]. Formed from sodium trimethylene trisulphone and PrI in alcohol (Camps, B. 25, 244). Slender needles, m. sol. boiling alcohol.

Hexa-propyl-trimethylene trisulphone  $\text{CPr}_2\text{SO}_2\text{CPr}_2\text{SO}_2\text{CH}_2\text{SO}_2\text{CPr}_2\text{SO}_2\text{CPr}_2$ . [133°]. Formed from the trisulphone, PrI, and alcoholic NaOH (Camps). Prisms.

ISO-PROPYL-NAPHTHALENE  $\text{C}_{10}\text{H}_{11}$ , i.e.  $\text{C}_{10}\text{H}_7\text{Pr}$ . (265°). V.D. 5-85. Formed by heating naphthalene with PrBr and  $\text{AlCl}_3$  (Roux, *B.* [2] 41, 379; A. Ch. [6] 12, 289). Oil, sol. alcohol and benzene. Yields (β)-naphthoic acid on oxidation.— $\text{B}^0\text{C}_6\text{H}_5\text{N}_3\text{O}_2$ . [90°]. Lemon-yellow needles.

PROPYL NITRATE  $\text{PrNO}_3$ . (110-5°) (Perkin, C. J. 55, 683). S.G.  $\frac{15}{15}$  1-0631;  $\frac{25}{15}$  1-0531. M.M. 4-085. Formed by distilling n-propyl alcohol with  $\text{HNO}_3$  and a little urea (Wallach a. Schulze, B. 14, 420). Forms with anthracene  $\text{C}_{10}\text{H}_7\text{PrNO}_3$  [92°] crystallising in four-sided prisms (Perkin, jun. a. Mackenzie, C. J. 61, 866).

Isopropyl nitrate  $\text{PrNO}_3$ . (102°). S.G. 2 1-054 (Silva, A. 154, 256).

Reference.—CHLORO-ISOPROPYL NITRATE.

PROPYL NITRITE  $\text{PrONO}$ . (43°-46°) (Cahours, C. R. 77, 749); (53°-60°) (Pribram a. Handl, M. 2, 655). S.G.  $\frac{21}{15}$  .935 (C.);  $\frac{9}{15}$  .998 (P. a. H.). Formed by passing nitrous acid gas into n-propyl alcohol.

Isopropyl nitrite  $\text{PrNO}_2$ . (44°). S.G. 2 .856;  $\frac{25}{15}$  .844 (Silva, *Bl.* [2] 12, 227; Kissel, J. R. 1882, 226).

PROPYL- $\alpha$ -NITROLE  $\text{C}_3\text{H}_7\text{N}_2\text{O}_2$ , i.e.

$\text{CH}_3\text{C}(\text{NO}_2)(\text{NO})\text{CH}_2$ . Mol. w. 118. [70°] (Bewad, B. 24, 976). Formed by adding  $\text{KNO}_3$  and dilute  $\text{H}_2\text{SO}_4$  to an alkaline solution of iso-nitro-propane  $\text{CHMe}_2\text{NO}_2$  (V. Meyer a. Locher, B. 7, 670; A. 175, 120). Monoclinic crystals, insol. water and alkalis. Forms a blue liquid when fused. Its solutions in alcohol and chloroform are blue.

PROPYL-NITROLIC ACID  $\text{C}_3\text{H}_7\text{N}_2\text{O}_3$ , i.e.  $\text{CH}_3\text{CH}_2\text{CH}(\text{NO}_2)\text{NO}$  or  $\text{CH}_3\text{CH}_2\text{C}(\text{NO}_2)\text{NOH}$ . [60°]. Formed by adding potassium nitrite and dilute  $\text{H}_2\text{SO}_4$  to an alkaline solution of nitro-propane  $\text{CH}_3\text{CH}_2\text{CH}_2\text{NO}_2$ . Formed also from  $\text{Et.CBr}_2\text{NO}_2$  and hydroxylamine (V. Meyer, B. 7, 670; 9, 395). Prisms, with sweet taste, v. sol. water, alcohol, and ether. Alkalis form a deep-red solution. Conc.  $\text{H}_2\text{SO}_4$  forms propionic acid and  $\text{N}_2\text{O}$ .

PROPYL OCTYL OXIDE  $\text{PrO.C}_8\text{H}_{17}$ . (207°). S.G.  $\frac{9}{15}$  .8039. C.E. (0°-10°). .00101. S.V. 272-4 (Dobriner, A. 243, 7).

DI-PROPYL OXIDE  $\text{PrO.PrO}$ . Propyl ether. (90-7° i.v.). S.G.  $\frac{9}{15}$  .7633 (Zander, A. 214, 163). C.E. (0°-10°) .00125 (Dobriner, A. 243, 20). S.V. 150-9. Formed from PrI and KOPr (Chancel, A. 151, 304). Got also from PrI and  $\text{Ag}_2\text{O}$  (Linnemann, A. 161, 37) and by heating n-propyl alcohol with  $\text{H}_2\text{SO}_4$  at 135° (Norton a. Prescott, *Am.* 6, 243).

Di-isopropyl oxide  $\text{Pr}_2\text{O}$ . (68-8° i.v.). S.G.  $\frac{9}{15}$  .7435. C.E. (0°-10°) .00130. S.V. 151-6 (Zander). Got from PrI and  $\text{Ag}_2\text{O}$  (Erlenmeyer, A. 126, 306).

PROPYL OXYBUTYL KETONE

$\text{C}_3\text{H}_7\text{CO.CH}(\text{OH})\text{C}_4\text{H}_9$ . Butyrolin. (180°-190°). Formed from di-n-propyl diketone and alcoholic KOH (Klinger a. Schmitz, B. 24, 1273). Yields a phenyl-hydrazide [135°].

PROPYL-PHENOL v. CUMENOL.

PROPYL-PHENOL CARBOXYLIC ACID v. OXY-CUMINIC ACID.

Isopropyl-phenol dicarboxylic acid  $\text{C}_6\text{H}_4\text{Pr}(\text{OH})(\text{CO}_2\text{H})_2$ . [295°]. Formed, together with oxy-cuminic acid, by the action of Na and  $\text{CO}_2$  on isopropyl-phenol (Fileti, G. 16, 126). Tables or needles, sol. water and alcohol.

p-PROPYL-PHENYL-ACETIC ACID

$\text{C}_6\text{H}_4\text{C}_3\text{H}_6\text{CH}_2\text{CO}_2\text{H}$ . [52°]. Formed by saponifying the nitrile, which is got from  $\alpha$ -chloro-cymene, alcohol, and KCy at 100° (Rossi, A. Suppl. 1, 130). Small needles (from hot water). —AgA': slender needles.

References.—AMIDO- and OXY-PROPYL-PHENYL-ACETIC ACID.

PROPYL-PHENYL-AMINE v. AMIDO-PHENYL-PROPANE and PROPYL-ANILINE.

ISO-PROPYL-PHENYL- v. CUMYL-.

ISO-PROPYL-PHENYL-CINNAMIC ACID

$\text{Pr.C}_6\text{H}_4\text{C}(\text{CHPh})\text{CO}_2\text{H}$ . [184°]. Formed from  $\text{Pr.C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{Na}$ , benzoic aldehyde, and  $\text{Ac}_2\text{O}$  (Magnanini, G. 15, 509). Needles (from dilute alcohol). —CaA'. —AgA'.

ISO-PROPYL-PHENYL-p-COUMARIC ACID.

Methyl derivative

$\text{Pr.C}_6\text{H}_4\text{C}(\text{CO}_2\text{H})\text{CH.C}_6\text{H}_4\text{OMe}$ . [199°]. Formed from  $\text{Pr.C}_6\text{H}_4\text{CH}_2\text{CO}_2\text{Na}$ , anisic aldehyde, and  $\text{Ac}_2\text{O}$  (Magnanini, G. 15, 511). Prisms (from alcohol). —AgA'.

DI-p-PROPYL-DI-PHENYL-CYANAMIDE  $\text{C}(\text{N.C}_3\text{H}_6\text{Pr})_2$ . [168°]. Formed by heating

**CS(NH.C<sub>6</sub>H<sub>5</sub>.Pr)**, with benzene and PbO (Frank-  
sen, *B.* 17, 1228). Needles.

**PROPYL-BENZONITRILE** *v.* *Nitrile of Co-*  
*minic acid.*

**ISOPROPYL - DI - PHENYL - ETHYLENE**  
**C<sub>6</sub>H<sub>5</sub>.CH:CH.C<sub>6</sub>H<sub>5</sub>.Pr.** [84°]. Formed by heat-  
ing phenyl-acetic acid with cuminic aldehyde  
and NaOAc at 250° (Michael, *Ann.* 1, 314).  
Scales (from alcohol), *v.* sl. sol. hot water.

**DI - p - PROPYL - DIPHENYL - GUANIDINE**  
**NH:C(NH.C<sub>6</sub>H<sub>5</sub>.Pr)<sub>2</sub>.** [113°]. Formed by heating  
di-propyl-di-phenyl-thio-urea with alcoholic NH<sub>3</sub>  
and PbO (Frankesen, *B.* 17, 1225). Needles, *v.*  
sol. warm alcohol and ether. — Platinumchlor-  
ide (C<sub>18</sub>H<sub>18</sub>N<sub>4</sub>)<sub>2</sub>.PtCl<sub>6</sub>: yellowish-brown pp.

**Tri-propyl-tri-phenyl-guanidine**  
**C<sub>6</sub>H<sub>5</sub>.Pr.N:C(NH.C<sub>6</sub>H<sub>5</sub>.Pr)<sub>3</sub>.** Formed by heating  
CS(NH.C<sub>6</sub>H<sub>5</sub>.Pr)<sub>3</sub> with C<sub>6</sub>H<sub>5</sub>.Pr.NH<sub>2</sub>, alcohol, and  
PbO. Amorphous resin, *v.* sol. alcohol. —  
B<sub>2</sub>H<sub>6</sub>.PtCl<sub>6</sub>: brown powder.

**pn-PROPYL-PHENYL METHYL KETONE**  
**CH<sub>3</sub>.CO.C<sub>6</sub>H<sub>4</sub>.Pr.** (259° i.v.). S.G. 1.2979.  
Formed from *n*-cumene, AcCl, and AlCl<sub>3</sub> (Wid-  
mann, *B.* 21, 2224). Colourless liquid. Yields  
an oxim [54°], which melts at 44° after fusion.  
The phenyl-hydrazide [92°] forms six-sided  
hatchet-shaped tables.

**Isomeride** CH<sub>3</sub>.CO.C<sub>6</sub>H<sub>4</sub>.Pr. (253°). Yields an  
oxim [71°] and a phenyl-hydrazide [82°].

**ISOPROPYL-PHENYL PHOSPHATE**  
**PO(O.C<sub>6</sub>H<sub>5</sub>.Pr)<sub>2</sub>.** (375°-380° at 280 mm.). Got  
from isopropyl-phenol and PBr<sub>3</sub> (Fietti, *G.* 16,  
130). Viscid liquid, insol. water, sol. alcohol.

**p - ISOPROPYL - (Py. 3) - PHENYL-QUINOL-**  
**INE** C<sub>10</sub>H<sub>11</sub>N *i.e.* C<sub>6</sub>H<sub>4</sub> $\begin{matrix} \text{CH}_2\text{CH} \\ \text{N} = \text{C}_6\text{H}_4\text{Pr} \end{matrix}$  [60°].  
Formed by heating its carboxylic acid with soda-  
lime (Dübner, *A.* 249, 102). Needles, sl. sol.  
water. — B<sub>2</sub>H<sub>6</sub>.PtCl<sub>6</sub> 2aq. — B<sub>2</sub>H<sub>6</sub>.Cr<sub>2</sub>O<sub>7</sub>. —  
Picrates: [195°]; plates (from alcohol).

**Carboxylic acid** C<sub>6</sub>H<sub>4</sub> $\begin{matrix} \text{C}(\text{CO}_2\text{H})\text{CH} \\ \text{N} = \text{C}_6\text{H}_4\text{Pr} \end{matrix}$   
[201°]. Formed from cuminic aldehyde, pyru-  
vic acid, and aniline (Dübner). Yellow plates  
(from HOAc). — AgA': white powder.

**p-PROPYL-PHENYL-THIOCARBIMIDE**  
**C<sub>6</sub>H<sub>5</sub>.Pr.N:CS.** (263°). Formed by heating di-  
propyl-di-phenyl-thio-urea with syrupy H<sub>2</sub>PO<sub>3</sub>  
(Frankesen, *B.* 17, 1223). Oil, volatile with  
steam, *v.* sol. alcohol and ether.

**p-PROPYL-PHENYL-THIO-UREA** C<sub>10</sub>H<sub>11</sub>N<sub>2</sub>S  
*i.e.* NH<sub>2</sub>.CS.NH.C<sub>6</sub>H<sub>4</sub>.Pr. [159°]. Formed from  
amido-phenyl-propane hydrochloride and am-  
monium sulphocyanide (Frankesen, *B.* 17, 1222).  
Needles, sol. alcohol and ether.

**Di-propyl-di-phenyl-thio-urea**  
**CS(NH.C<sub>6</sub>H<sub>5</sub>.Pr)<sub>2</sub>.** [138°]. Formed from amido-  
phenyl-propane, CS<sub>2</sub>, and alcohol (F.). Plates.

**PROPYL-PHENYL-UREA** C<sub>10</sub>H<sub>11</sub>N<sub>2</sub>O *i.e.*  
**NH<sub>2</sub>.CO.NHC<sub>6</sub>H<sub>4</sub>.Pr.** [143°]. Formed by the  
action of potassium cyanate on amido-phenyl-  
propane hydrochloride (Frankesen, *B.* 17,  
1225). Plates, sol. hot alcohol, insol. water.

**Di-p-propyl-di-phenyl-urea** CO(NHC<sub>6</sub>H<sub>4</sub>.Pr)<sub>2</sub>  
[205°]. Formed by heating amido-phenyl-  
propane with urea. Formed also by the action  
of COCl<sub>2</sub> on amido-phenyl-propane in benzene,  
and by heating amido-phenyl-propane sulphate  
with a saturated solution of potassium cyanate.  
Needles, *v.* sol. ether and hot alcohol.

**PROPYL PHOSPHATE PO(OPr)<sub>3</sub>.** Formed,  
together with PrCl and PO(OH)<sub>2</sub>(OPr) (which is  
sol. water) by the action of PCl<sub>5</sub> on *n*-propyl  
alcohol (Winssinger, *Bl.* [2] 48, 111). Oil. *V.*  
sl. sol. water, its insolubility being greatest  
at 75°. Cannot be distilled, even *in vacuo*.

**ISOPROPYL-PHOSPHINE** PrPH<sub>3</sub>. (41°).  
Formed, together with Pr<sub>2</sub>PH (118°) and Pr<sub>3</sub>P,  
by heating PrI with PH<sub>3</sub>I and ZnO for 6 hours  
at 100° (Hofmann, *B.* 6, 292). Liquid, with  
penetrating odour. Readily absorbs oxygen,  
taking fire on a hot day. — B'III: decomposed by  
water.

**Tri-isopropyl-phosphine** Pr<sub>3</sub>P. Oil. Forms  
red crystals with CS<sub>2</sub>. — Pr<sub>3</sub>PH<sub>4</sub>. Large crystals,  
*v.* sol. water. — Pr<sub>3</sub>PI. Cubes or octahedra.

**Di-chloro-isopropyl-phosphine** PrPCL<sub>2</sub>. (α.  
135°). Formed by heating H<sub>2</sub>Pr<sub>2</sub> with PCl<sub>5</sub>  
(Michaelis, *B.* 13, 2175). Liquid.

*Reference.* — OXY-TRI-PROPYL-PHOSPHINE.  
**PROPYL PHOSPHITE P(OPr)<sub>3</sub>.** (240°).  
S.G. 1.2004. Formed from PCl<sub>5</sub> and NaOPr  
(Jaehne, *A.* 256, 282). Liquid. •

**ISOPROPYL-ISOPHTHALIC ACID**  
**C<sub>6</sub>H<sub>4</sub>Pr(CO<sub>2</sub>H)<sub>2</sub>** [13:5]. [285°]. Formed by  
heating pyruvic acid with isobutyric aldehyde  
and Ba(OH)<sub>2</sub> (Doebner, *B.* 23, 2380; 24, 1748).  
Plates (from dilute alcohol, *v.* sl. sol. cold water).  
— BaA'' 2½aq. CalA'' 2½aq. — Ag<sub>2</sub>A'' aq.

**PROPYL-PHYCITE.** According to Faucon-  
nier (*C. R.* 107, 629), the substance described  
under this name by Carius (*A.* 134, 71) is  
glycerin.

**PROPYL-PIPERIDINE** *v.* **PROPYL-PYRIDINE**  
**HEXAHYDRIDE.**

**PROPYL-PROPANE** *v.* **HEXANE.**  
**(a)-PROPYL-PYRIDINE** C<sub>6</sub>H<sub>5</sub>N *i.e.*  
**N<CH<sub>2</sub>.CH<**  
**CH:Pr.CH>CH.** *Conyrrine.* (169°). Formed

by distilling coniine hydrochloride with zinc-  
dust (Hofmann, *B.* 17, 825; Ladenburg, *A.* 247,  
20). Light oil, with blue fluorescence. Yields  
picolinic acid [131°] on oxidation. Reduced by  
conc. HIAq at 290° to coniine. — B<sub>2</sub>H<sub>6</sub>.PtCl<sub>6</sub>  
[160°] and [172°]. Orange monoclinic tables.  
*a:b:c* = 1.0622:1.15356; β = 87° 13'. — B'Mel.  
Oil. — B<sub>2</sub>Me<sub>2</sub>PtCl<sub>6</sub>. Crystals, sl. sol. water.

**Tetrahydride** NH<CH<sub>2</sub>.CH<sub>2</sub>>CH<sub>2</sub> or  
CH<sub>2</sub>.CH<sub>2</sub>.CH<sub>2</sub>.C<CH<sub>2</sub>.CH<sub>2</sub>>CH<sub>2</sub>. This is (γ)-  
coniine (vol. ii. p. 248). Yields coniine on re-  
duction with tin and HCl (Lohmann a. Müller,  
*B.* 23, 680).

**Hexahydride** NH<CH<sub>2</sub>.CH<sub>2</sub>>CH<sub>2</sub>. In-  
active coniine. (167°). S.G. 9.8626. Formed  
by reducing (α)-allyl-pyridine (derived from (α)-  
methyl-pyridine and paraldehyde) in alcoholic  
solution with sodium (Ladenburg, *B.* 19, 2579;  
*A.* 247, 80). Oil, optically inactive. Can be  
separated by means of the acid tartrate into a  
dextro-modification (coniine) and a lavo-  
modification. — B'HCl. [203°] (L.); [213°] (L. a. M.).  
*V.* sol. water. — B<sub>2</sub>H<sub>6</sub>.PtCl<sub>6</sub>. — B<sub>2</sub>H<sub>6</sub>Cl<sub>4</sub>. [118°].

**(β)-Propyl-pyridine** N<CH<sub>2</sub>.CH<  
CH:Pr.CH>CH. *Col-*  
*lidine.* (170°). Got by passing nicotine through  
a red-hot tube (Cahours a. Etard, *J.* 1881, 928).  
Yields nicotinic acid on oxidation.

(a) - Isopropyl - pyridine  $N \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{CPr} \cdot \text{CH} \end{smallmatrix} \text{CH}$ . (159°). S.G. 2.9342. Formed, together with the (γ)-isomeride, by heating pyridine with PrI and PrI at 290° (Ladenburg, B. 17, 772, 1121; 18, 1587; A. 247, 22). Liquid, with unpleasant odour, sl. sol. water. Gives picolinic acid on oxidation with  $\text{KMnO}_4$ .— $\text{B}'_2\text{H}_2\text{PtCl}_6$ . [170°]. Hexagonal rhombohedra,  $a:c = 1:9489$ .— $\text{B}'\text{HAuCl}_4$ . [91°].— $\text{B}'\text{C}_2\text{H}_2\text{N}_2\text{O}_4$ . [116°]. Needles. Mercuric chloride double salt: [90°].— $\text{B}'\text{MeAuCl}_4$ . [128°].

Tetra-hydride  $\text{C}_5\text{H}_7\text{N}$ . (164°). S.G. 2.896. Formed from the hexahydride, Br, and  $\text{NaOHAq}$  (Ladenburg, B. 20, 1646).— $\text{B}'_2\text{H}_2\text{PtCl}_6$ . [189°]. Tables.

Hexahydride  $\text{C}_5\text{H}_9\text{N}$  i.e.

$\text{NH} \begin{smallmatrix} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CHPr} \cdot \text{CH}_2 \end{smallmatrix} \text{CH}_2$ . (159°). S.G. 2.8668. Formed by reduction in alcoholic solution by Na (Ladenburg, A. 247, 73). Liquid, more sol. cold than hot water. Converted by MeI into  $\text{NMe} \begin{smallmatrix} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CHPr} \cdot \text{CH}_2 \end{smallmatrix} \text{CH}_2$ . (167°).  $\text{CS}_2$  yields  $(\text{C}_5\text{H}_7\text{N})_2\text{CS}_2$ . [105°].— $\text{B}'\text{HCl}$ . [210°]. Trimetric prisms;  $a:b:c = 814:1:419$ .— $\text{B}'\text{HBr}$ . [233°].— $\text{B}'\text{HI}$ . [243°].— $\text{B}'_2\text{H}_2\text{PtCl}_6$ . [193°]. Monoclinic prisms;  $a:b:c = 977:1:385$ ;  $\beta = 89^\circ 88'$ .— $\text{B}'_2\text{H}_2\text{CdI}_4$ . [133°].

ν-Propyl-pyridine hexahydride

$\text{NPr} \begin{smallmatrix} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH}_2 \end{smallmatrix} \text{CH}_2$ . (149°–150°). Formed from piperidine and PrI (Ladenburg, B. 14, 1348). Liquid.— $\text{B}'_2\text{H}_2\text{SnCl}_4$ : monoclinic crystals.

ν-Isopropyl-pyridine hexahydride

$\text{NPr} \begin{smallmatrix} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH}_2 \end{smallmatrix} \text{CH}_2$ .— $\text{B}'_2\text{H}_2\text{SnCl}_4$ : monoclinic crystals (Hjortdahl, J. 1882, 1085).— $\text{B}'_2\text{H}_2\text{PtCl}_6$ .

(γ) - Isopropyl - pyridine  $N \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{CH} \cdot \text{CH} \end{smallmatrix} \text{CPr}$ . (178°). S.G. 2.9439. Formed as above, being separated by means of the platinochloride, which is more soluble than that of the (α)-isomeride. Oil. Yields isonicotinic acid [305°] on oxidation.— $\text{B}'_2\text{H}_2\text{PtCl}_6$ . [205°]. Plates.

Hexahydride  $\text{NH} \begin{smallmatrix} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH}_2 \end{smallmatrix} \text{CHPr}$ .

(171°). Formed by reducing (γ)-isopropyl-pyridine in alcoholic solution by Na. Fuming liquid, v. sol. cold water.— $\text{B}'_2\text{H}_2\text{PtCl}_6$ . [172°]. Golden prisms, sl. sol. water.

References.—OXY-PROPYL-PYRIDINE and OXY-PROPYL-PYRIDINE.

PROPYL PYRIDYL KETONE v. PYRIDYL PROPYL KETONE.

PROPYL - PYROGALLOL  $\text{C}_5\text{H}_7\text{O}$ , i.e.  $\text{C}_5\text{H}_7\text{Pr}(\text{OH})_2$ . [80°]. Got by heating its di-methyl ether with conc.  $\text{HClAq}$  at 130° (Hofmann, B. 8, 67; 11, 329). Prisms (from benzene), v. e. sol. water and alcohol.  $\text{FeSO}_4$  colours its aqueous solution blue (Pastrovitch, M. 4, 182).

Methyl ether  $\text{C}_5\text{H}_7\text{Pr}(\text{OH})(\text{OMe})$ . (290° cor.). S.G. 1.1023. Occurs, together with the di-methyl ether, in beech-wood tar (Pastrovitch). Oil, with smoky smell. Gives an intense bluish-green colour with  $\text{FeCl}_3$  in alcohol.— $\text{C}_5\text{H}_7\text{Pr}(\text{OK})(\text{OMe})$ . Pearly crystals (from dilute alcohol).— $\text{C}_5\text{H}_7\text{Pr}(\text{OAc})(\text{OMe})$ . [83°]. Needles (from alcohol).— $\text{C}_5\text{Br}_2\text{Pr}(\text{OAc})(\text{OMe})$ . [79°]. Golden needles.

Di-methyl ether  $\text{C}_5\text{H}_7\text{Pr}(\text{OH})(\text{OMe})_2$ . Picamar. (c. 286° cor.). Occurs in beech-wood tar (Reichenbach, A. 8, 224; Niederist, M. 4, 487). Oil, with bitter, burning taste. Reduces salts of Au and Ag. Yields the di-methyl ether of di-oxy-quinone on oxidation.— $\text{C}_5\text{H}_7\text{Pr}_2\text{O}_2\text{K}$ . Pearly leaflets (from spirit).— $\text{C}_5\text{H}_7\text{Pr}_2\text{O}_2$ . [87°]. Monoclinic prisms;  $a:b:c = 39:1:547$ ;  $\beta = 96^\circ 29'$ .— $\text{C}_5\text{H}_7\text{Pr}_2\text{O}_2\text{Ac}$ . [101°]. Trimetric prisms;  $a:b:c = 99:1:193$ .— $\text{C}_5\text{H}_7\text{Pr}_2\text{O}_2$ . [91°]. Tri-methyl ether  $\text{C}_5\text{H}_7\text{Pr}(\text{OMe})_3$ . (164°). Formed from propyl-pyrogallol and MeI (Will, B. 21, 2020).

n-PROPYL-PYRROLE  $\text{C}_5\text{H}_7\text{N}$  i.e.

$\text{NPr} \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{CH} \cdot \text{CH} \end{smallmatrix}$ . (147°). Formed from potassium pyrrole and PrI (Zanetti, B. 22, 2518). Liquid. Isopropyl-pyrrole  $\text{C}_5\text{H}_7\text{PrN}$ . (174°). Formed by boiling pyrrole with acetone and  $\text{ZnCl}_2$  (Dennstedt a. Zimmermann, B. 20, 851; 21, 1480). Liquid. Dry  $\text{HCl}$  passed into its ethereal solution forms  $(\text{C}_5\text{H}_7\text{N})_2\text{HCl}$ , a crystalline salt yielding a liquid base (c. 287°) and a picrate  $(\text{C}_5\text{H}_7\text{N})_2\text{C}_6\text{H}_3\text{N}_3\text{O}_7$ . [146°].  $\text{Ac}_2\text{O}$  forms  $\text{C}_5\text{H}_7\text{PrN} \cdot \text{Ac}$  (222°–232°) and  $\text{C}_5\text{H}_7\text{AcPrN} \cdot \text{NH}$  [64°] (261°).

ISOPROPYL-PYRROL STYRYL KETONE

$\text{NHC}_5\text{H}_7\text{Pr.CO.CH} \cdot \text{CHPh}$ . [143°]. Formed by boiling  $\text{NiCl}_2 \cdot \text{H}_2\text{Pr.CO.CH}_3$  with benzoic aldehyde and dilute  $\text{KOH}$  (Dennstedt a. Zimmermann, B. 20, 853). Yellow crystals.

(B. 3)-ISOPROPYL-QUINOLINE  $\text{C}_{12}\text{H}_{11}\text{N}$  i.e.

$\text{CH} \cdot \text{CH} \cdot \text{C} \cdot \text{CH} \cdot \text{CH}$  Cumoquinoline. Formed by heating (Py. 3)-chloro-isopropyl-quinoline with a solution of HI in  $\text{HOAc}$  (Widman, B. 19, 267). Oil, easily volatile in steam.—Salts:  $\text{B}'_2\text{H}_2\text{PtCl}_6$  2aq. [220°].—Picrate: [206°].—Chromate: [c. 92°]. Large red prisms. Methyl-iodide  $\text{B}'\text{MeI}$ . [c. 200°].

(Py. 2)-Isopropyl-quinoline

$\text{C}_5\text{H}_7 \begin{smallmatrix} \text{CH} \cdot \text{CPr} \\ \text{N} = \text{CH} \end{smallmatrix}$ . [c. 10°]. (275°–280°) at 715 mm. Formed by distilling its (Py. 3)-carboxylic acid (Spady, B. 18, 3383). Liquid, v. sol. alcohol and ether.— $\text{B}'_2\text{H}_2\text{PtCl}_6$ .— $\text{B}'_2\text{H}_2\text{Cr}_2\text{O}_7$ .— $\text{B}'\text{C}_2\text{H}_2\text{N}_2\text{O}_4$ : long slender needles.

(Py. 3)-Isopropyl-quinoline  $\text{C}_5\text{H}_7 \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{N} = \text{CPr} \end{smallmatrix}$ .

(255°). Formed by heating its (Py. 1)-carboxylic acid with soda-lime (Doebner, B. 20, 279; A. 242, 279). Oil, smelling like quinoline.— $\text{B}'_2\text{H}_2\text{PtCl}_6$  2aq: yellow needles.— $\text{B}'\text{C}_2\text{H}_2\text{N}_2\text{O}_4$ . [150°]. Yellow plates (from alcohol).

Reference.—CHLORO- and OXY-ISOPROPYL-QUINOLINE.

(Py. 2)-ISOPROPYL-QUINOLINE (Py. 3)-

CARBOXYLIC ACID  $\text{C}_5\text{H}_7 \begin{smallmatrix} \text{CH} \cdot \text{CPr} \\ \text{N} = \text{C.CO}_2\text{H} \end{smallmatrix}$ . [189°].

Formed by oxidation of (Py. 2,3)-isopropyl-isobutyl-quinoline with  $\text{CrO}_3$  and dilute  $\text{H}_2\text{SO}_4$  (Spady, B. 18, 3379). Plates (from dilute alcohol).— $\text{AgHA} \cdot \text{HNO}_3$ .— $(\text{HA})_2 \cdot \text{H}_2\text{PtCl}_6$ : prisms.

(Py. 3)-Isopropyl-quinoline (Py. 1)-carboxylic acid  $\text{C}_5\text{H}_7 \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \cdot \text{CH} \\ \text{N} = \text{CPr} \end{smallmatrix}$ . [146°]. Formed, together with  $\text{C}_5\text{H}_7\text{N}_2\text{O}$  (222°), by adding aniline to an alcoholic solution of isobutyric aldehyde and pyruvic acid (Doebner, A. 242, 276; B. 20, 279). Prisms (containing 1½ aq).—

**HA<sub>2</sub>TeCl** — (HA)<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub>aq. — (HA)<sub>2</sub>H<sub>2</sub>NaCl<sub>4</sub>: lemon-yellow needles. — AgA'.

**PROPYL SILICATE** Si(OPr)<sub>3</sub>. (226°). S.G. 1.2-915 (Cahours, C. R. 76, 1383). On heating with SiCl<sub>4</sub> at 160° it yields (PrO)<sub>2</sub>SiCl<sub>2</sub> (209°) and (PrO)<sub>4</sub>SiCl<sub>2</sub> (187°).

**DI-PROPYL-DI-STYRYL KETONE** (C<sub>6</sub>H<sub>5</sub>)<sub>2</sub>C<sub>6</sub>H<sub>4</sub>CH<sub>2</sub>CH<sub>2</sub>CO. [106°]. Formed from cuminic aldehyde, acetone, alcohol, and NaOHAq (Claisen a. Ponder, A. 223, 148). Prisms.

**ISOPROPYL-STYRYL-PHENOL**. *Methyl ether*. C<sub>6</sub>H<sub>5</sub>Pr.CH:CH.C<sub>6</sub>H<sub>4</sub>OMe. [152°]. Got by heating C<sub>6</sub>H<sub>5</sub>Pr.CO(CO<sub>2</sub>H):CH.C<sub>6</sub>H<sub>4</sub>OMe (Magnanini, G. 15, 513). Pearly scales (from alcohol).

**PROPYL-SUCCINIC ACID** C<sub>10</sub>H<sub>16</sub>O<sub>4</sub>, i.e. CO<sub>2</sub>H.CH<sub>2</sub>.CHPr.CO<sub>2</sub>H. *Oxy-hexic acid*. [92°]. Formed by heating pentane tri-carboxylic acid (Waltz, B. 15, 608; A. 214, 59). Got also by reducing oxy-hexic acid with zinc and H<sub>2</sub>SO<sub>4</sub> (Gorboff, J. R. 1887, 605; Walden, B. 24, 2036).

**Iso-propyl-succinic acid** v. PMELIC ACID.

**Di-isopropyl-succinic acid** C<sub>10</sub>H<sub>18</sub>O<sub>4</sub>, i.e. CO<sub>2</sub>H.CHPr.CHPr.CO<sub>2</sub>H. [168°]. The ether is formed from α-bromo-isovaleric ether and finely-divided silver (Hell a. Mayer, B. 22, 48). Dendritic crystals (from water). — BaA'' 5aq. S. 7-7 at 17°. — CuA'' aq. S. 0.99 at 24°. — SrA'' 3aq. — CaA'' 4aq. — MgA'' 7aq. — CoA'' 7aq. — NiA'' 5aq. — CdA'' 4aq. — MnA'' 7aq. S. 4-71 at 21°. — ZnA'', — PbA'', — Ag<sub>2</sub>A''. S. 0.62 at 20°.

**Isomeride** C<sub>10</sub>H<sub>16</sub>O<sub>4</sub>. [200°]. Accompanies the preceding acid. Granular crystals. — BaA'' 2aq. — SrA'' 4aq. — CaA'' 2aq. — MgA'' 5aq. — MnA'' 3aq. — NiA'' 4aq. — CuA'' 3aq. — CdA'' 3aq. — ZnA'' — PbA'' — Ag<sub>2</sub>A''.

**Reference** — OXY-PROPYL-SUCCINIC ACID.

**TETRA-PROPYL-SUCCINIMIDINE** C<sub>16</sub>H<sub>28</sub>N<sub>2</sub>, i.e. CH<sub>2</sub>:C(NPr)<sub>2</sub>>N. Got from succin-imido-ethyl ether hydrochloride, NHPr, and alcohol at 50° (Pinner, B. 23, 2930). — B'21NO<sub>3</sub>. [53°]. — B'<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub>. [174°]. Needles, sl. sol. hot water.

**PROPYL SULPHATES**.

**Propyl sulphuric acid** PrOSO<sub>3</sub>OH. Formed from propyl alcohol and H<sub>2</sub>SO<sub>4</sub> (Chancel, C. R. 37, 410). — KA': needles, v. sol. water. — BaA'' 3aq (Schmidt, Z. 1870, 576).

**Di-propyl sulphate** Pr<sub>2</sub>SO<sub>4</sub>. Formed from propyl alcohol and ClSO<sub>3</sub>OH (Mazurowska, J. pr. [2] 13, 162). Oil.

**DI-n-PROPYL SULPHIDE** Pr<sub>2</sub>S. (142°) (Winssinger, Bl. [2] 48, 109). S.G. 1.2-814 (C). Occurs in raw petroleum (Mabery a. Smith, B. 22, 3303). Formed by heating K<sub>2</sub>S with PrCl or PrI in alcohol (Cahours, C. R. 76, 133). Fetid oil. Bromo-acetic acid forms the acid Pr.SBr.CH<sub>2</sub>.CO<sub>2</sub>H, which yields Pb<sub>2</sub>A'Br<sub>2</sub> and Pb<sub>2</sub>A'Br<sub>2</sub> (Letts, Tr. E. 23, 586).

**Compounds with platinum salts** (Blomstrand, J. pr. [2] 33, 354, 498). — (Pr<sub>2</sub>S)<sub>2</sub>PtCl<sub>4</sub>. Occurs in three varieties: (α) [46°] S. (alcohol) 15-6 at 15°, (β) [86°], and (γ) [63°]. Alcoholic KOH (1 mol.) acting on the (α)-compound forms crystalline (Pr<sub>2</sub>S)<sub>2</sub>PtCl(OH). — (Pr<sub>2</sub>S)(Et<sub>2</sub>S)PtCl<sub>2</sub>: syrup. — (Pr<sub>2</sub>S)<sub>2</sub>PtCl<sub>4</sub>. [185°]. — (Pr<sub>2</sub>S)<sub>2</sub>PtCl<sub>4</sub>. [189°]. — (Pr<sub>2</sub>S)PtCl<sub>2</sub>. Prisms. — (Pr<sub>2</sub>S)<sub>2</sub>PtBr<sub>2</sub>. [105°]. — (Pr<sub>2</sub>S)<sub>2</sub>PtBr<sub>2</sub>. [141°]. — (Pr<sub>2</sub>S)<sub>2</sub>PtBr<sub>2</sub>Cl<sub>2</sub>. [129°]. — (Pr<sub>2</sub>S)<sub>2</sub>PtI<sub>2</sub>. [133°]. Red prisms. — (Pr<sub>2</sub>S)<sub>2</sub>PtI<sub>2</sub>. [161°]. Crystals. — (Pr<sub>2</sub>S)(Et<sub>2</sub>S)PtI<sub>2</sub>. [115°]. — (Pr<sub>2</sub>S)(Pr<sub>2</sub>S)PtI<sub>2</sub>. [181°]. — (Pr<sub>2</sub>S)<sub>2</sub>Pt(NO<sub>3</sub>)<sub>2</sub>. Occurs in two forms

[210°] and [195°]. — (Pr<sub>2</sub>S)<sub>2</sub>Pt(NO<sub>3</sub>)<sub>2</sub>. Occurs in two varieties, an oil and a crystalline body [70°] which yields (Pr<sub>2</sub>S)<sub>2</sub>Pt(NO<sub>3</sub>)<sub>2</sub>(OH) [145°]. — (Pr<sub>2</sub>S)<sub>2</sub>PtCrO<sub>4</sub>. Red prisms (from chloroform). (Pr<sub>2</sub>S)<sub>2</sub>PtC<sub>2</sub>O<sub>4</sub>: crystalline pp. — (Pr<sub>2</sub>S)<sub>2</sub>Pt(SCN)<sub>2</sub>: yellow pp. — (Pr<sub>2</sub>S)<sub>2</sub>PtCl<sub>2</sub>HgCl<sub>2</sub>. [82°]. Trimetric crystals, a:b:c = 554:1:591.

**Propyl-iodide** SP<sub>3</sub>I. Yields the compound (SP<sub>3</sub>Cl)<sub>2</sub>PtCl<sub>4</sub> (Cahours).

**Isopropyl sulphide** Pr<sub>2</sub>S. (121° i.v.). Formed by distilling PrI with alcoholic K<sub>2</sub>S (Henry, B. 2, 495; Beckmann, J. pr. [2] 17, 459). Oxidised by KMnO<sub>4</sub> to Pr<sub>2</sub>SO<sub>4</sub> [36°]. Yields Pr<sub>2</sub>SHgCl<sub>2</sub>.

**Compounds with salts of platinum** (Blomstrand): — (Pr<sub>2</sub>S)<sub>2</sub>PtCl<sub>4</sub>. [163°]. — (Pr<sub>2</sub>S)<sub>2</sub>PtBr<sub>2</sub>. [174°]. — (Pr<sub>2</sub>S)<sub>2</sub>PtI<sub>2</sub>. [176°]. — (Pr<sub>2</sub>S)<sub>2</sub>Pt(SCN)<sub>2</sub>. [102°]. — (Pr<sub>2</sub>S)<sub>2</sub>Pt(NO<sub>3</sub>)<sub>2</sub>. Prisms, decomposing at 210°. — (Pr<sub>2</sub>S)<sub>2</sub>PtI<sub>2</sub>. [189°].

**Di-propyl disulphide** Pr<sub>2</sub>S<sub>2</sub>. (193°). (Spring a. Legros, B. 15, 1940).

**Di-isopropyl disulphide** Pr<sub>2</sub>S<sub>2</sub>. (175°). A product of the action of Na and MeI on isopropyl mercaptan in ether (Obermeyer, B. 20, 2928).

**PROPYL SULPHOCYANIDE** PrSCN. (163°). Liquid (Schmidt, Z. 1870, 576).

**Isopropyl sulphocyanide** PrSCN. (150°) (Henry, B. 2, 490); (153°) (Gerlich, A. 178, 90). S.G. 2.963. Formed from PrI and potassium sulphocyanide. Liquid, decomposed by boiling water. H<sub>2</sub>S yields NH<sub>4</sub>CS<sub>2</sub>Pr [97°].

**DI-n-PROPYL SULPHONE** Pr<sub>2</sub>SO<sub>2</sub>. [80°]. Formed by oxidising Pr<sub>2</sub>SO (Winssinger, Bl. [2] 48, 111). Scales, sol. water, alcohol, and ether Volatile with steam.

**Di-isopropyl sulphone** Pr<sub>2</sub>SO<sub>2</sub>. [36°]. Got by oxidising Pr<sub>2</sub>S with KMnO<sub>4</sub> (Beckmann, J. pr. [2] 17, 459). V. sol. water and HClAq. Not affected by reducing agents.

**DI-PROPYL SULPHONE DICARBOXYLIC ACID** SO<sub>2</sub>(CH<sub>2</sub>Et.CO<sub>2</sub>H)<sub>2</sub>. *Sulpho-dibutyric acid*. [152°]. Formed from SO<sub>2</sub>(CH<sub>2</sub>CO<sub>2</sub>Et)<sub>2</sub>, EtI, and NaOEt (Lovén, B. 17, 2817). Dimetric octahedra.

**Di-isopropyl sulphone dicarboxylic acid** SO<sub>2</sub>(CMe<sub>2</sub>CO<sub>2</sub>H)<sub>2</sub>. [188°]. Formed from SO<sub>2</sub>(CH<sub>2</sub>CO<sub>2</sub>Et)<sub>2</sub> (1 mol.), MeI (4 mols.) and NaOEt (4 mols.) (Lovén, B. 17, 2824).

**DI-PROPYL SULPHOXIDE** Pr<sub>2</sub>SO. [15°]. Got by oxidising Pr<sub>2</sub>S with dilute HNO<sub>3</sub> (S.G. 1-2) (Winssinger, B. 16, 829; Bl. [2] 48, 110). Needles, sol. water, alcohol, and ether. Decomposed by heat. Readily reduced to Pr<sub>2</sub>S. Calcium nitrate forms (Pr<sub>2</sub>SO)<sub>2</sub>Ca(NO<sub>3</sub>)<sub>2</sub>, a fibrous mass [80°].

**β-ISOPROPYLTHIENYL ETHYL KETONE** C<sub>6</sub>H<sub>5</sub>PrS.CO.C<sub>2</sub>H<sub>5</sub>. (251°). Formed from (β)-isopropylthiophene, propionyl chloride, and AlCl<sub>3</sub> (Thiele, A. 267, 136). Oil, volatile with steam. Appears to yield isopropyl-thienylglyoxylic acid on oxidation with alkaline KMnO<sub>4</sub>.

**PROPYL-THIENYL GLYOXYLIC ACID** C<sub>6</sub>H<sub>5</sub>PrS.CO.CO<sub>2</sub>H. Formed by oxidising propyl thienyl methyl ketone with alkaline KMnO<sub>4</sub> (Ruffi, B. 20, 1745). Solid. — AgA'.

**PROPYL-THIENYL METHYL KETONE** C<sub>6</sub>H<sub>5</sub>PrS.CO.CH<sub>3</sub>. (255°). Formed by the action of AcCl and AlCl<sub>3</sub> on a solution of (α)-propylthiophene in ligroin (Ruffi, B. 20, 1744). Liquid. Yields an oxim [55°] and a phenylhydrazide [60°].

**Isopropylthienyl methyl ketone**

$\text{C}_6\text{H}_4\text{PrS.CO.CH}_3$ . (237°). Formed from isopropylthiophene,  $\text{AcCl}$ , and  $\text{AlCl}_3$  (Thiele, *A.* 267, 187). Oil. Yields a crystalline oxim and phenyl-hydrazide.

**PROPYL-DI-THIO-BIURET**  $\text{C}_6\text{H}_4\text{N}_2\text{S}_2$  *i.e.*  $\text{NH}_2\text{.CS.NH.CS.NHPr}$ . [121°]. Formed from sodium cyanamide and propylthiocarbimide (Hecht, *B.* 25, 754). Crystalline mass, v. sl. sol. cold water.

**PROPYL-THIOCARBIMIDE**  $\text{PrN:CS}$ . (153°). S.G.  $\frac{16}{4}$  9909;  $\frac{20}{4}$  8924. Formed from propylamide and  $\text{CS}_2$  followed by  $\text{HgCl}_2$  (Hecht, *B.* 23, 281, 1662). Pungent liquid, sl. sol. water, miscible with alcohol and ether. Sodium cyanamide and alcoholic  $\text{MeI}$  form  $\text{NHPr.CS.NCyMe}$  [115°]. In the same manner may be prepared  $\text{NHPr.CS.NCyEt}$  [56°],  $\text{NHPr.CS.NCyC}_6\text{H}_5$  [50°],  $\text{NHPr.CS.NCyPr}$  [56°] crystallising in needles, and  $\text{NHPr.CS.NCy.C}_6\text{H}_4\text{Ph}$  [113°].

**Isopropyl-thiocarbimide**  $\text{PrN:CS}$ . (137°). Pungent liquid (Jahn, *M.* 3, 168).

**PROPYL DI-THIO-CARBONATE**  $\text{PrO.CS.SH}$ . Unstable oil.— $\text{PrO.CS.SK}$ . Formed from  $\text{CS}_2$  and  $\text{KOH}$  dissolved in propyl alcohol (Scala, *G.* 17, 78). Silky needles. Its aqueous solution gives an orange pp. with  $\text{CuSO}_4$ . Iodine forms oily ( $\text{PrO.CS}$ ),  $\text{S}_2$  decomposing at 180°. —  $\text{PrO.CS.SMe}$ . (202°). Oil.— $\text{PrO.CS.SET}$ . (216°).

(a) **PROPYL-THIOPHENE**  $\text{C}_6\text{H}_4\text{PrS}$ . (159° cor.). S.G.  $\frac{19}{4}$  974. Formed from iodothiophene,  $\text{PrBr}$ , and  $\text{Na}$  (Meyer & Kreis, *B.* 17, 1561). Oil. Yields (a)-thiophenic acid on oxidation.

**Isopropylthiophene**  $\text{C}_6\text{H}_4\text{PrS}$ . (154° cor.). S.G.  $\frac{18}{4}$  9695. Formed from  $\text{PrBr}$ , thiophene, and  $\text{AlCl}_3$  (Schleicher, *B.* 19, 672). Oil with powerful odour. With  $\text{HOAc}$ , phenanthraquinone, and  $\text{H}_2\text{SO}_4$ , it gives a deep violet colour.

**$\beta$ -Isopropylthiophene**  $\frac{\text{CPr:CH}}{\text{CH:CH}} > \text{S}$ . (158°).

Formed by distilling sodium isopropylsuccinate with  $\text{P}_2\text{S}_5$  (Thiele, *A.* 267, 133). Oil, smelling like benzene, insol. water, miscible with alcohol, ether, and benzene. Forms  $\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{S.HgCl}$  [137°] crystallising from alcohol in white needles, and  $\text{C}_6\text{H}_4\text{C}_6\text{H}_4\text{S.HgCl}_2$  as white grains, insol. alcohol (Volhard, *A.* 267, 183).

*References.* — Bromo-, Iodo-, and Nitro-PROPYL-THIOPHENE.

**PROPYL-THIOPHENE CARBOXYLIC ACID**  $\text{C}_6\text{H}_4\text{PrS.CO}_2\text{H}$ . [57°]. Formed from iodo-propylthiophene,  $\text{ClCO}_2\text{Et}$ , and sodium-amalgam; the product being saponified by alcoholic potash (Ruff, *B.* 20, 1743). Needles (from warm water), or plates (from dilute alcohol).

**PROPYL THIOSULPHATE**. The salt  $\text{PrS.SO}_3\text{Na}$  5aq is made from  $\text{Na}_2\text{S}_2\text{O}_3$  and  $\text{PrI}$  (Spring & Legros, *B.* 15, 1938).

**PROPYL-THIO-UREA**  $\text{NHPr.CS.NH}_2$ . [110°]. Formed from propylthiocarbimide and  $\text{NH}_4\text{Aq}$  in the cold (Hecht, *B.* 23, 233). Four-sided plates, sol. alcohol.

**Isopropyl-thio-urea**  $\text{NHPr.CS.NH}_2$ . [157°]. Plates (Jahn, *M.* 3, 168).

**Di-propyl-thio-urea**  $\text{CS(NHPr)}_2$ . [71°]. Formed in the preparation of propylthiocarbimide. Pearly plates (from water).

**Di-isopropyl-thio-urea**  $\text{CS(NHPr)}_2$ . [161°]. Needles (from hot water) (Jahn).

**PROPYL-TOLUENE o. Cymene.**

**PROPYL-TOLUIC ACID o. Cymene carboxylic acid.**

**n-PROPYL-p-TOLUIDINE**  $\text{C}_6\text{H}_4\text{N}$  *i.e.*  $\text{C}_6\text{H}_4\text{Me.NHPr}$ . (232°). S.G.  $\frac{23}{4}$  9296.  $\mu_D = 1.5367$ . S.V. 197.53.  $R_D = 82.5$ . Formed by heating *p*-toluidine (1 mol.) with  $\text{PrI}$  (1 mol.) for two days at 160°; the yield being 90 p.c. of the theoretical amount (Hori & Morley, *C. J.* 59, 36). Purified by means of the nitrosamine. Oil. Salts.— $\text{B}^+\text{HCl}$ . [151°]. Needles (from boiling benzene), v. sol. water and alcohol.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ . [173°]. S. (alcohol) 1:4 at 21°. Ppd. on mixing alcoholic solutions of the base (1 mol.) and oxalic acid (1 mol.). Sl. sol. cold water and alcohol.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ . [117°]. Occurs in the filtrate from the preceding salt, and formed also when a large excess of base is added to a cold alcoholic solution of the acid oxalate. Crystals, m. sol. cold water and alcohol. Decomposed by boiling water,  $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$  being ppd.— $\text{B}^+\text{H}_2\text{FeCy}_4$ . Nitrosamine  $\text{C}_6\text{H}_4\text{Me.NPr.NO}$ . Oil, not solid at  $-20^\circ$ . Decomposes below 100°.

**Isopropyl-p-toluidine**  $\text{C}_6\text{H}_4\text{Me.NPr.NO}$ . (220° uncor.). S.G.  $\frac{23}{4}$  9129.  $\mu_D = 1.5322$ . S.V. 199.57.  $R_D = 81.4$ . Formed by heating  $\text{PrI}$  with *p*-toluidine for two days at 130° (Hori & Morley, *C. J.* 59, 34). Got also by heating diazo-toluene toluidide  $\text{C}_6\text{H}_4\text{N}_2\text{NHCO}_2\text{H}$  with alcoholic  $\text{NaOEt}$  and  $\text{PrI}$  for 5 hours on the water-bath, distilling off the alcohol, pouring into water, and decomposing the pp. with  $\text{HCl}$ . Oil.

Salts.— $\text{B}^+\text{HCl}$ . [171°]. Wax-like crystals (from alcohol) or needles (from benzene), v. sol. water.— $\text{B}^+\text{H}_2\text{C}_2\text{O}_4$ . [130°]. S. (alcohol) 5:76 at 22°. Crystals (from dilute alcohol). The acid oxalate is not easily crystallisable.— $\text{B}^+\text{H}_2\text{FeCy}_4$ .

**Nitrosamine**  $\text{C}_6\text{H}_4\text{Me.NPr.NO}$ . [59°]. S. (alcohol) 6:5 at 22°. Yellowish crystals (from alcohol), not volatile with steam.

*Reference.* — Oxy-PROPYL-TOLUIDINE.

**PROPYL-UREA**  $\text{NH}_2\text{CO.NHPr}$ . [107°]. Formed from propyl cyanate and  $\text{NH}_3$ , and from potassium cyanate and propylamine sulphate (Chance, *B.* [3] 9, 101). Long needles, sol. water and alcohol. Its oxalate and nitrate are v. sol. water. Decomposed by  $\text{HClAq}$  in a sealed tube at 160° into  $\text{NH}_3$ ,  $\text{NH}_4\text{Pr}$ , and  $\text{CO}_2$ . **Butyryl derivative**  $\text{NHPr.CO.NH(CO.C}_6\text{H}_5)$ . [99°]. Formed by the action of cold  $\text{KOHaq}$  on a mixture of butyramide (2 mols.) and bromine (1 mol.) (Hofmann, *B.* 15, 757). Colourless plates, sl. sol. water.

**Isopropyl-urea. Isobutyryl derivative**  $\text{NHPr.CO.NH.COPr}$ . [86°]. Formed in like manner from the amide of isobutyric acid. Tables, sol. alcohol and ether.

**$\alpha$ -Di-propyl-urea**  $\text{NH}_2\text{CO.NPr}_2$ . [57°]. Formed from dipropylamine and  $\text{KCyoO}$ . Needles (from alcohol). Its oxalate crystallises in needles, sl. sol. water.

**$\beta$ -Di-propyl-urea**  $\text{CO(NHPr)}_2$ . [105°]. (255°). Got by boiling the corresponding thio-urea with  $\text{HgO}$  and water (Hecht, *B.* 23, 285), or from  $\text{PrCyO}$  and aqueous  $\text{NH}_4\text{Pr}$ . White plates (from water). Sl. sol. cold water, v. sol. alcohol and ether. Its salts are decomposed by water.

**Di-propyl-urea**  $\text{C}_6\text{H}_4\text{N}_2\text{O}$  *i.e.*  $\text{NH}_2\text{CO.NPr}_2$ . [76°]. Formed from propylamine sulphate and potassium cyanate (Von der Zande, *Z. T. C.* 8, 228). Needles. An ethereal solution of aldehyde forms  $\text{CH}_3\text{CH(NH.CO.NPr)}_2$ , [118°]. Chloral

hydrate gives  $\text{CCl}_4 \cdot \text{CH}(\text{OH}) \cdot \text{NH} \cdot \text{CO} \cdot \text{NPr}_2$  [128°] and in aqueous solution  $(\text{C}_6\text{H}_5)_3\text{N}_2\text{O} \cdot \text{C}_2\text{H}_5\text{Cl} \cdot \text{Oaq}$  [51°].  $\epsilon$ -Nanthalol in ethereal solution gives  $\text{C}_6\text{H}_5 \cdot (\text{NH} \cdot \text{CO} \cdot \text{NPr}_2)_2$  [113°]. —  $\text{B}' \cdot \text{H}_2\text{C}_2\text{O}_4$ . [103°]. —  $\text{B}' \cdot \text{C}_2\text{H}_4\text{N}_2\text{O}_4$ . [135°]. —  $\text{B}' \cdot 2\text{HNO}_3$ .

**s-Di-isopropyl-urea**  $\text{CO}(\text{NHPr})_2$ . Formed as a by-product in the production of isopropyl cyanate from isobutyric bromo-amide and  $\text{Na}_2\text{CO}_3$  (Hofmann, B. 15, 756). Needles, sol. alcohol, insol. ether.

**u-Di-isopropyl-urea**  $\text{NH}_2 \cdot \text{CO} \cdot \text{NPr}_2$ . [103°]. Formed by evaporating a solution of isopropylamine sulphate with potassium cyanate (Von der Zande, R. T. C. 8, 231). Crystals (from ether). An ethereal solution of aldehyde forms  $\text{CH}_3 \cdot \text{CH}(\text{NH} \cdot \text{CO} \cdot \text{NPr}_2)_2$  [147°]. Chloral in ethereal solution gives  $\text{CCl}_4 \cdot \text{CH}(\text{OH}) \cdot \text{NH} \cdot \text{CO} \cdot \text{NPr}_2$  [121°]. —  $\text{B}' \cdot \text{H}_2\text{C}_2\text{O}_4$ . [111°]. Needles. —  $\text{B}' \cdot \text{C}_2\text{H}_4\text{N}_2\text{O}_4$ . [134°]. Needles. —  $\text{B}' \cdot \text{HNO}_3$ . [79°].

Reference.—DI-BROMO-PROPYL-UREA.

PROTAGON v. LECTHIN.

**PROTAMINE**  $\text{C}_8\text{H}_{21}\text{N}_3\text{O}_3$  or  $\text{C}_8\text{H}_{21}\text{N}_3\text{O}_4$ . Occurs in the seminal substance of the salmon in November (Miescher, B. 7, 376; Piccard, B. 7, 1714). Gummy mass, insol. alcohol and ether, sol. water with alkaline reaction. Its salts give with  $\text{K}_2\text{FeCy}_6$  a milky pp. composed of minute drops. Salts. —  $(\text{C}_6\text{H}_5)_3\text{N}_2\text{O}_3 \cdot \text{H}_2\text{PtCl}_6$  (M.);  $\text{C}_6\text{H}_5\text{N}_3\text{O}_3 \cdot \text{H}_2\text{PtCl}_6$  (P.). Yellow powder.

**PROTEIDS**. (*Protein*, 'pre-eminence.') This name is given to a large group of organic compounds which are also known as 'albuminous.' The word 'proteid' itself has been retained simply as a convenient general term, and not as implying any adherence to the theory, first advanced by Mulder, that they all contain a complex molecule to which he gave the name of 'protein.' The word *albumin* is now limited to a certain class of proteids, and the word *albuminoid*, though it is still largely used synonymously with proteid, is restricted by physiological chemists to a class of nitrogenous substances (which includes such substances as gelatin and mucin) which are not proteids, but still in certain reactions resemble those substances closely.

Proteids are never absent from the protoplasm of active living cells, whether animal or vegetable, and they are indissolubly connected with every manifestation of organic activity. A definition of proteids is not possible in the logical sense. Gamgee (*Physiol. Chem.* p. 4) gives in the following sentences a terse description of these substances, which must take the place of a definition: 'Proteids are highly complex, and for the most part non-crystallisable compounds of carbon, hydrogen, nitrogen, oxygen, and sulphur, occurring in a solid viscous condition or in solution in nearly all the solids and liquids of the organism. The different members of the group present differences in physical, and to a certain extent in chemical, properties; they all possess, however, certain common chemical reactions, and are united by a close genetic relationship.'

In vegetables the proteids are constructed out of the simpler chemical compounds which serve as their food. In animals such a synthesis never occurs, but the proteids are derived directly or indirectly from vegetables. By the action of certain digestive juices all proteids are capable of being converted into closely allied substances

called peptones, which after absorption undergo reconversion into proteids.

Although much work has been done in attempting to unravel the constitution of the proteids, there is at present but little positive to be said on this point. All we can do is to give the result of the experiments that have been performed which show the classes of products yielded by the proteids, and to enumerate the various theories held by different observers concerning their constitution.

The various proteids differ somewhat in elementary composition within the limits of the following numbers (Hoppe-Seyler, *Handbuch d. Phys. und Path.-Chem. Analyse*, 4to Aufl. p. 223):

	C	H	N	S	O
From	51.5	6.9	15.2	0.3	20.9
To	54.5	7.3	17.0	2.0	23.5

The various decompositions that proteids undergo may be conveniently stated under the following heads:—

**a. Decomposition in the body.** In the alimentary canal the proteids are converted into proteoses (albumoses) and peptones; this change is probably due to hydration. Under the influence of the pancreatic ferment, a certain class of peptones called hemi-peptones are further acted upon, resulting in the formation of leucine, tyrosine, aspartic acid, ammonia, and protein-chromogen (a substance coloured purple by bromine). Putrefactive processes due to bacteria in the small intestine also occur; these result in the formation of indole, skatole, phenol, and oxyacids. Ethereal hydrogen sulphates can be detected in the urine as a result of these putrefactive changes (Baumann, H. 10, 123); when putrefaction is hindered by the administration of large doses of iodoform in dogs, these products do not appear in the urine (V. Morax, H. 10, 318). One of the sources of hippuric acid in the urine of flesh-feeders is the  $\alpha$ -phenyl-propionic acid that results from the putrefaction of proteids in the alimentary tract (Salkowski, B. 12, 648; Tappenier, Z. B. 22, 236).

After the proteids have been absorbed from the alimentary canal, they become assimilated by the tissues, and there undergo combustion or metabolism, the chief ultimate products being water, carbonic acid, and urea. It is probable that glycocine, leucine, creatine, and ammonium carbonate are intermediate products in this change. Urea had not been obtained from proteids by experiments performed outside the body until quite recently, when Drechsel (B. 23, 3096) has succeeded in obtaining a crystalline base lysatin by acting on casein with zinc and hydrochloric acid. Lysatin yields urea when boiled with baryta water. It has also been demonstrated, by experiments on animals, that proteid food gives rise to glycogen in the liver, and to fat in the subcutaneous and other tissues. That proteids can be converted into fats is also shown by the occurrence of *adipocere* in the muscular tissues after death.

**b. Action of heat.** By dry distillation the proteids yield an oily liquid called *Dippel's oil*, which contains ammoniacal salts of the fatty acids, amines, and aromatic compounds.

**c. Action of putrefaction.** The chief products

are ammonia, ammonium sulphide, carbonic acid, volatile fatty acids, lactic acid, amines, mucine, tyrosine, and other complex aromatic compounds.

*d. Action of acids and alkalis.* Prolonged boiling with strong sulphuric or hydrochloric acid, or fusion with caustic alkalis, gives rise to a large number of products, of which the following are the most important: leucine, tyrosine, aspartic acid, and glutamic acid. Prolonged heating with dilute acids gives rise to hydrolytic decomposition (Hermann) and the formation of albumoses and peptones (Neumeister, *Z. B.* 23, 381).

The effect of heating proteids with caustic baryta was investigated by Nasse, and subsequently by Schützenberger (*Bt. Feb.* 15, March 5 and 15, 1875). Ammonia was evolved, and carbonic acid remained in combination with barium; these two products occurred in the same ratio as would result from urea similarly treated. In addition oxalic acid, acetic acid, tyrosine, amido-acids of the fatty acid series (especially leucine, butylamine, and amido-butyric acid), acids allied to glutamic and aspartic acids, and lastly a dextrin-like substance, were found in the residue. Schützenberger (*A. Ch.* [5] 16, 289) explains the mechanism of the reaction as follows: the proteid molecule, losing ammonia and carbon as carbonic oxalic, and acetic acids, and assimilating water, is converted into a mixture of glucoproteins  $C_8H_{12}N_2O_8$ , containing as its principal term  $C_8H_{12}N_2O_8$ ; by the prolonged action of baryta at a high temperature these split up partly into leucines or amido-acids of the acetic series  $C_8H_{12}N_2NO_8$ , and leucines or amido-acids of the acrylic series  $C_8H_{12}N_2NO_8$ , and partly into double compounds formed by the union of glucoproteins and leucines with the leucines. For Schützenberger's recent attempts to synthesise proteids see *C. R.* 112, 198.

*e. Action of hydrochloric acid and stannous chloride.* Ammonia, aspartic acid, glutamic acid, leucine, and tyrosine are the chief products (Hlasiwetz & Habermann, *Anz. Wien. Acad.* 1872, 1878; *A.* 159, 304; 169, 150; *J. pr.* 7, 897).

*f. Action of oxidising agents.* By means of manganese dioxide and sulphuric acid, or potassium chromate and sulphuric acid, many fatty and aromatic compounds are formed. Nitric acid produces first a yellow insoluble substance, xantho-proteid acid, which dissolves on further action, and yields ultimately para-oxybenzoic and oxybenzoic acids.

Mulder (*J. pr.* 16, 129; 17, 312; *A.* 31, 129) obtained by the action of potash on proteids a substance which is now called alkali-albuminate, but which was regarded by Mulder to be the base of all proteids; he gave it the name 'protein.' Various definite compounds of protein were described, such as oxyprotein, trioxypotein, sulphoproteid acid, &c. Liebig (*A.* 57, 132) was the first to disprove these assertions, and the only remnant of this theory now is the term 'proteid.' For recent work on this subject and the related one of sulphur in proteids see Danilewski (*H.* 7, 440), and Krüger (*Pf.* 43, 244).

Gerhardt was of opinion that all the proteids are identical in constitution and molecular arrangement, but differ from one another in the

nature of the mineral substance with which they are associated. He designated the common organic element by the name 'albumin,' and it may be mentioned that in the elaboration of his theory he regarded egg albumin as the neutral albumate of sodium, and fibrin as a compound of albumin with earthy phosphates. Proteids, however, have been separated from all but traces of mineral matter, and still exhibit their peculiar characteristics; careful elementary analysis also has shown that there is a difference of the percentage amounts of carbon, nitrogen, sulphur, &c., in various proteids. Nevertheless, it is still a fact that some of the distinguishing features of certain proteids are due to the adhering salt; for instance, the coagulation of caseinogen by reunit occurs only in the presence of calcium salts (Hammarsten).

Gautier (*Chimie appliquée à la Physiologie*, i. 251) states that the proteids behave as amides of the higher homologues of lactic and tartaric acids, and residues of aromatic acids; hence when proteids are oxidised there is a simultaneous production of fatty acids, of aromatic compounds, and doubtless of bodies analogous to urea; the products furnished by different proteids are not in the same proportions. It must, therefore, follow that the different radicals they contain differ not only in arrangement but in relative proportion, and sometimes even in their nature. It was Nasse who first observed (*Pf.* 6, 589) that the nitrogen in proteids appears to exist in two conditions, a certain fraction of it being more unstable and apparently more feebly combined than the rest. This view was fully confirmed by Schützenberger in the experiments already alluded to. The latter observer regards the proteids as complex *ureides*, i.e. combinations in various proportions of urea with amido-acids, some of which belong to the leucine series, others to the aspartic series. Representing albumin by the empirical formula  $C_{22}H_{32}N_4O_{12}S$  (Lieberkühn), it yields, when decomposed by caustic baryta, urea, acetic acid, a sulphur-containing body, and a substance with the formula  $C_{10}H_{12}N_2O_8$ , which may on further hydration be split up into the substances already mentioned (glucoproteins, leucines, leucines, &c.).

Pflüger's view relative to the constitution of the proteids (*Pf.* 10, 251) may be thus summarised. One of the most striking features of the proteids is the difference that exists between non-living proteid matter, such as white of egg, and that which forms part of living protoplasm. The former may remain for years without undergoing decomposition, and is indifferent to neutral oxygen; while the latter is continually decomposing, undergoing intramolecular changes, and lives by breathing oxygen. The assimilation of proteid food is looked upon by Pflüger as an ether-like combination of a molecule of living proteid with one of the non-living proteid, water being eliminated. This union of isomeric molecules, which forms a heavy mass but still remains a simple molecule, may be conceived to go on indefinitely. In this process it seems probable that the nitrogen of the food proteid, which exists there in combination as amides, passes into combination with carbon, so that in living proteid it is combined in the form of cyanogen. This view is strengthened by the fact that sub-

stances like uric acid, creatine, and guanine, are products of proteid metabolism, while such compounds are never obtained from non-living proteid material. O. Loew (*Die chemische Kraftquelle im Lebenden Protoplasma*, Munich, 1892, B. A. 1885, p. 1075) has also found that a striking difference between living and non-living proteids is the fact that the former reduce silver nitrate, probably owing to some radicle of the nature of aldehyde, whereas the latter do not behave in this way. He suggests that albumin is a condensation product of aspartic aldehyde. The simplest formula for Schützenberger's leucine  $C_6H_9NO_2$  is also that of aspartic aldehyde.

Latham (*Brit. Med. Journ.* [1] 1886, 629) regards albumin as a compound of cyan-alcohols united to a benzene nucleus. The cyan-alcohols resemble proteids in readily undergoing condensation and intramolecular changes; and, moreover, the various products of the disintegration of proteids can also be obtained as the decomposition products of these cyan-alcohols. See also Drechsel's art. in Ladenburg's *Handw. d. Chem.* 3, 541; Beilstein's *Handb.* 3, 1258.

#### GENERAL PROPERTIES OF PROTEIDS.

1. *Indiffusibility.* Solutions of proteids are non-diffusible. They belong to Graham's class of colloid substances. Peptones, and to a less extent albumoses, are, however, diffusible. This property of indiffusibility enables us to separate proteids from saline admixtures, and also to separate various proteids from one another: e.g. if a mixture of albumin and globulin in a saline solution be dialysed, the salts pass out, the albumin remains within the dialyser in solution, while the globulin, which is insoluble in water, is precipitated.

2. *Action on polarised light.* Proteids all rotate the plane of polarised light to the left. The following table gives the specific rotatory power for the yellow line D of some of the chief proteids:

Proteid	Observer	Value of $[\alpha]_D$
Serum albumin . . . .	Hoppe-Seyler ( <i>Zeit. f. Chem. und Pharm.</i> 1864, 737)	-56°
Egg albumin . . . .	Starke ( <i>Maly's Jahrs.</i> 11, 17)	-60°
	Hoppe-Seyler . . . .	-83.5°
	Haas ( <i>P.</i> 12, 378)	-39.08°
Fibrinogen . . . .	Haas ( <i>C. C.</i> 1876, 295, 811, 824)	-59.75°
	Hermann ( <i>H.</i> 11, 508)	-43°
Sodium albumate . . . .	Haas . . . .	-55°
Syntonin (from egg albumin) . . . .	Haas . . . .	-63.12°
Syntonin (from myosin) . . . .	Hoppe-Seyler . . . .	-72°
Casein (in weak $MgSO_4$ solution) . . . .	Hoppe-Seyler . . . .	-80°
Serum globulin . . . .	Haas . . . .	-59.75°
Various albumoses . . . .	Kühne & Chittenden ( <i>Z. B.</i> 20, 51)	-70° to 80°

According to Haas, these numbers are unaltered by the salts adherent to the proteids.

3. *Heat coagulation.* Most of the native proteids are coagulated by heating their solutions, but more especially the globulins and albumins. By this means the character of the original proteid is lost, and all are converted into an exceedingly insoluble substance, called 'coagulated proteid.' When several proteids are mixed in a solution, if their temperature of coagulation differs, it is possible to separate them by a process of 'fractional heat coagulation.' The heat coagulation temperature

of various proteids is usually characteristic, but it can be varied somewhat by additions of small quantities of acid or alkali; the former lowers, the latter heightens, the coagulation temperature. Alkali albumin in the latter case is not coagulable by heat, and forms so readily that it is advisable to have the solution either perfectly neutral or faintly acid before performing the experiment. Rendering the liquid faintly acid with weak (2 p.c.) acetic acid also renders the flocculi of precipitate larger and easier to filter off. The alkalinity of a liquid is always increased, or its acidity diminished, after the separation of a heat coagulum. Various neutral salts in excess also cause the coagulation temperature to vary; sodium chloride lowers the temperature, while magnesium sulphate has little or no effect. A solution of proteid enters into an opalescent condition a few degrees below that at which the separation of flocculi begins. In the dry state proteids are rendered insoluble, like coagulated proteid, at a temperature of 110° C. On the influence of salts on coagulation temperatures, see Limbourg (*H.* 13, 450). Hagercraft criticises the method of fractional heat coagulation (*Pr. Roy. Soc. Edin.* 1898-9, 361). It is defended by numerous observers (for references see Halliburton, *J. Physiol.* 13, 806; Hewlett, *ibid.* 798).

The following table gives the heat coagulation temperatures of some of the most important proteids:

Proteid	Temperature of heat coagulation
Egg albumin . . . .	72.8° C.
Serum albumin a . . . .	72.3°
Vitellin . . . .	75°
Serum globulin . . . .	75°
Fibrinogen . . . .	56°
Myosin . . . .	56°
Crystallin . . . .	93°
Hæmocyanin . . . .	65°

4. *General tests for proteids.* Solutions of the proteids are precipitated by strong mineral

acids, acetic acid and potassium ferrocyanide, by acetic or oxalic acid together with a large addition of concentrated solutions of neutral salts, by basic lead acetate, by mercuric chloride, by copper sulphate, by tannic acid, by saturation with powdered potassium carbonate, ammonium sulphate or sodium-magnesium sulphate, and by alcohol.

Strong acids and salts of the heavy metals produce a precipitate of coagulated proteid, or of metallic albuminate; in the latter case the metal can be removed by treatment with sulphuretted hydrogen, and the proteid again ob-

tained unaltered. Neutral salts like ammonium sulphate, or sodio-magnesium sulphate, completely precipitate all proteids but peptones, and in an uncoagulated condition—i.e. they can be re-dissolved in water or weak saline solutions, and exhibit their characteristic properties. Alcohol precipitates proteids, and after long contact with the precipitate converts them into 'coagulated proteid.' The following reactions are those most frequently employed in the detection of proteids in solution:

(a) *The xanthoproteic reaction.* Nitric acid is added; this usually produces a precipitate, but in the case of peptones, or if the quantity of proteid is very small, it does not. The mixture is then boiled, when the liquid and the precipitate turn yellow (xanthoproteic acid); if it is boiled sufficiently long with excess of acid the precipitate dissolves. Addition of ammonia causes the yellow colour to become orange. A similar reaction is given by gelatin and keratin. Analyses of xanthoproteic acid and its compounds made by Mulder and others are not of any value, as it has since been shown that this yellow substance is not constant in composition. The reaction is due to the aromatic radicle undoubtedly present in all proteids. On colour reactions of proteids see Salkowski (*II*, 12, 215), Gnezda (*Pr*, 47, 202), Pickering (*J. Physiol.* 14).

(b) The liquid is rendered strongly acid with acetic acid, and solution of potassium ferrocyanide added, which throws down the proteid as a white flocculent precipitate.

(c) *Millon's reaction.* Millon's reagent<sup>1</sup> causes a white precipitate of the proteid. On boiling this precipitate and the surrounding liquid, both turn a brick-red colour. If only a trace of proteid is present there may be no initial precipitation. This test is given also by tyrosine, and it is in all probability owing to the aromatic radicle in proteids that those substances give it.

(d) Addition of a trace of copper sulphate and excess of potassium hydroxide causes a violet solution. In the case of albumoses and peptones the colour produced is a pink one (biuret reaction). See also Gnezda a. Pickering (*loc. cit.*) for similar reactions with nickel and cobalt.

(e) Proteids when dissolved in glacial acetic acid and treated with strong sulphuric acid exhibit a violet colour and faint fluorescence, and if sufficiently concentrated show an absorption spectrum very like that of urobilin (Adamkiewicz, *B*, 8, 161).

The reactions which are applicable to proteids which will not dissolve in water or neutral saline liquids, are the xanthoproteic, Millon's, and the Adamkiewicz colour reactions.

#### QUANTITATIVE ESTIMATION OF PROTEIDS.

A large number of different methods of estimating quantitatively the amount of proteid in a solution have been proposed and used; the polarimetric method has been much employed (Hoppe-Seyler, *Virchow's Archiv*, 11, 547). Among gravimetric methods various precipitants

<sup>1</sup> *Millon's reagent.* Equal quantities of mercury and strong nitric acid are mixed and gently warmed till the mercury is dissolved. The solution is diluted with twice its bulk of water, and the copious precipitate which forms allowed to settle. The supernatant liquid is the reagent.

of proteids have been suggested, e.g. tannin and sodium chloride (Girgensohn, *N. R. P.* 22, 557); hydrochloric acid and potassium-mercuric iodide (Brücke, *Sitz. W.* 1871), &c.; but the following methods are those most frequently employed:

(a) *Clinical method.* The rough method generally used for the comparison of albuminous urines consists in acidulating the urine, if it is alkaline, with acetic acid and then boiling it in a graduated tube. The flocculi which form are allowed to settle, and the proportion of the precipitate to the total volume of the liquid read off and expressed in fractions, such as a half, a tenth, and so on. Esbach's tubes are graduated to correspond to percentages of proteid; the precipitant being picric acid.

(b) *Precipitation by heat.* 50 to 100 c.c. of water are boiled and an accurately-weighed amount of albuminous fluid, about 15 or 20 g., poured in. The fluid is boiled for some minutes, a few drops of two per cent. acetic acid added, until the precipitate separates in flakes from a clear liquid. The precipitate is collected on a weighed filter, washed with water, alcohol, and ether, and finally dried, weighed, incinerated, and the ash deducted. This method is obviously applicable only to such proteids as are coagulable by heat.

(c) *Precipitation by alcohol.* An accurately measured or weighed quantity of the liquid is mixed with three or four times its volume of spirits of wine, and set aside for some hours; the precipitate is then collected, washed with spirit, hot absolute alcohol, ether, warm water, and finally dried and weighed as before (Hoppe-Seyler, *Handbuch*, 3te Aufl. 312). Or the liquid may be neutralised with acetic acid and mixed with ten times its volume of strong alcohol, and then boiled, the precipitate being treated as before (A. Schmidt, *Pf.* 11, 10; A. Hoffmann, *Virchow's Archiv*, 1879, 255).

(d) *Precipitation with ammonium sulphate.* Since Kühne (*Z. B.* 22, 423) has fully shown that saturation with this salt causes complete precipitation of all proteids but peptones, this method may be employed as follows for the quantitative estimation of these proteids:—The liquid is shaken or stirred with excess of the powdered salt, filtered, and the precipitate washed with saturated solution of ammonium sulphate. The filter with adherent proteid and salt is dried at 110°, by which means the proteid is rendered insoluble, and the salt can then be washed away with distilled water. The precipitate is then washed with alcohol and ether, dried, and weighed as before.

#### CLASSIFICATION OF PROTEIDS.

I. *Albumins.* These are proteids which are soluble in water, and not precipitable from their solutions by saturation with sodium chloride or magnesium sulphate. They are coagulated by heat. The important members of the group are egg albumin, serum albumin, and lactalbumin.

II. *Globulins.* These are proteids which are insoluble in water; they are soluble in dilute solutions of neutral salts; and are precipitated in an uncoagulated condition by saturation with sodium chloride and magnesium sulphate. They are coagulated by heat. The most im-

portant members of the group are: serum globulin, fibrinogen, myosin, crystallin, and globin.

III. *Albuminates*. This name is applied to the metallic compounds of proteids, and also to acid albumin or syntonin, and alkali-albumin. Restricting the term to the two latter substances, they may be defined as proteids insoluble in water or in solutions of neutral salts, but readily soluble in dilute acids or alkalis. Their solutions are not coagulated by heat.

IV. *Proteoses*. These are proteids which are not coagulable by heat, and most of them are precipitable by saturation with certain neutral salts. They are precipitated by nitric acid, the precipitate dissolving on the application of heat and reappearing when the solution is cooled. They resemble peptones in being slightly diffusible, and in giving the biuret reaction. They are formed from other proteids as the result of the action of proteolytic ferments on them, being an intermediate stage in the formation of peptones. They are also found in certain animal and vegetable tissues. The best-known members of the group are the albumoses.

V. *Peptones*. These are proteids which are very soluble in water; they are not precipitated by heat, by saturation with any neutral salt, nor by nitric acid. They are completely precipitated by tannin, by excess of absolute alcohol, and by potassio-mercuric iodide; incompletely by phosphotungstic acid, phosphomolybdic acid, and picric acid. They give the biuret reaction. Peptones are subdivided into hemipeptones, those which yield leucine and tyrosine as the further result of pancreatic digestion, and antipeptones, those which do not.

VI. *Insoluble proteids*. This class includes a number of proteids varying in their reactions which cannot be included in any of the foregoing classes, but which all resemble one another in their extreme insolubility in various reagents. This class includes fibrin, coagulated proteid, lardacein, antialbumid, and gluten.

#### DESCRIPTION OF THE PROPERTIES OF INDIVIDUAL PROTEIDS.

It will now be convenient to take the most important members of the various foregoing groups, and describe the characteristic properties of each. The animal proteids will be taken first.

CLASS I., ALBUMINS.—Egg albumin. This is the albumin occurring in white of egg; it may be separated from the globulin, which also occurs in that situation, by precipitating the latter with dilute acetic acid, or by saturation with magnesium sulphate. It is coagulated at a temperature of 70°–73°C. By fractional heat coagulation further pps. are obtained at 76° and 82° (Corlin a. Berard, *Arch. de Biol.* 9, 1). Its specific rotation is –35.5°. It is precipitated by agitation with ether. Crystalline egg albumin may be obtained by addition of an equal vol. of sat. sol. of ammonium sulphate and filtration to remove ovoglobulin. On slow evaporation of the filtrate, crystals of egg albumin form (Hofmeister, *H.* 14, 165; Gabriel, 15, 456).

Lieberkühn ascribed to albumin the formula  $C_{12}H_{11}N_3SO_{12}$ , Schützenberger  $C_{12}H_{12}N_3O_3S_7$ , Harnack (*H.* 5, 207)  $C_{12}H_{12}N_3O_3S_7$ . Since Lieberkühn attempted to establish the molecular weight of albumin by preparing and analysing

the copper compound, various investigations have been published bearing on the nature and composition of the compounds of albumin with the heavy metals, and especially with copper (F. Rose, Mitscherlich, Harnack, Bielitzki, Ritt-hausen, Lassaigne, &c. Further particulars will be found, with references to literature, in a paper by R. H. Chittenden and H. H. Whitehouse in *Studies from the Laboratory of Physiol. Chem., Yale University*, 2, 95). The results obtained are most contradictory, and illustrate that numerous compounds may be obtained by slightly modifying the conditions of precipitation; they are also very liable to dissociation. The only other proteid the metallic compounds of which have been studied is myosin; the percentage amount of the various metals in the compounds obtained differ from those formed from egg albumin (Chittenden a. Whitehouse, *l.c.*).

*Uses of albumin*. It is much used for clarifying vinous and syrupy liquids, as when boiled with it the heat coagulum carries down colouring matter and other impurities. In cookery white of egg is employed for this purpose, but in large operations, such as sugar refining, blood serum is used. Albumin is also largely used in photography, and in calico-printing for fixing colours. Its property of forming a hard compound with lime renders it useful as a cement in repairing earthenware. Spoilt albumin in print works may be recovered for practical purposes by the action of pepsin (Wagner a. Witz, *D. P. J.* 119, 166).

*Serum albumin*. This is the albumin occurring in serum. Its specific rotation is –56°. Fractional heat coagulation, and elementary analysis show that it is probably not a single proteid but consists in warm-blooded animals of three,  $\alpha$ ,  $\beta$ , and  $\gamma$ , coagulating respectively at 73°, 77°, 84° (v. Bloon). Aronstein a. A. Schmidt (*Pf.* 2, 1) stated that serum albumin completely freed from salts by prolonged dialysis does not coagulate by heat. This statement has not been confirmed by subsequent observers, who have found it impossible to free serum albumin from ash by this method, and have attributed the non-coagulation to a slight alkaline residue (Heynsius, *Pf.* 9, 514; Winogradoff, 2, 605; Hinzinga, 2, 392; Haas, 2, 378). On ash-free albumin see also Harnack, *B.* 22, 3046; 23, 3745. Serum albumin is not coagulated by ether. It is the proteid which most frequently occurs in morbid urine.

Serum albumin is not precipitated by saturating the serum with magnesium sulphate; if, however, the globulin precipitated by this method be filtered off, and the filtrate saturated with sodium sulphate, the albumin is precipitated; this is due to the formation of sodium-magnesium sulphate ( $MgSO_4.Na_2SO_4.6H_2O$ ) in the liquid (Halliburton, *Journ. of Physiol.* [5] 152). Albumin having nearly the same characters as serum albumin is found also in milk, muscle, lymphatic glands, and other tissues in small quantities.

CLASS II., GLOBULINS.—Serum globulin. (Synonyms, *paraglobulin*, *fibrinoplastin*, *serum-casein*.) This is the globulin occurring in serum. It is soluble in weak solutions of sodium chloride; it is partially precipitated when the

percentage of sodium chloride reaches 0.03 to 0.07, re-dissolved on the addition of more salt, and again precipitated, though never completely, when the amount of salt present is 20 p.c. It is completely precipitated by saturation with magnesium sulphate. It does not coagulate on the addition of fibrin ferment, and probably takes no part in the formation of fibrin (*v. art. Bloor*; *v. also Hammarsten, Pf. 17, 447; 18, 39*). Its heat coagulation temperature is 75°C.

The following methods have been suggested for the separation of the globulin from the albumin of serum:

(a) *Dialysis.* When the salts are dialysed out, the globulin is precipitated, the albumin remains in solution.

(b) Dilute the serum to 10 or 15 times its volume with water, and pass a stream of carbonic acid through it, the globulin is precipitated (*A. Schmidt, Arch. f. Anzt. u. Physiol. 1862, 429*); it is also partially precipitated by the addition of very weak acetic acid when the serum is similarly diluted (*Panum, Arch. f. Pathol. Anat. 4*); it was on account of this that a special alkali albumin or serum casein was formerly believed to exist in the blood.

(c) Saturation with sodium chloride precipitates the globulin, leaving the albumin in solution (*A. Schmidt*).

(d) Saturation with magnesium sulphate (*Hammarsten*). This is the only method commonly employed which effects a complete separation. *Kauder* has stated that half-saturation with ammonium sulphate will act similarly, and *Halliburton (loc. cit.)* that sodium acetate and sodium nitrate may also be used.

Serum globulin may be estimated quantitatively in serous liquids in the following way: a weighed or measured quantity of the liquid is saturated with magnesium sulphate, the precipitate collected on a weighed filter and washed with a saturated solution of magnesium sulphate, and then dried at 110°C. for some hours; the proteid is thus rendered insoluble, and is freed from the salt by washing with water and alcohol. The precipitate is again dried on the filter to constant weight, weighed, and subsequently ignited and the ash deducted. In such a liquid as serum, viz. one containing a mixture of globulin and albumin, the latter may be estimated by deducting the amount of globulin from the amount of total proteids present.

*Cell globulin* found in lymph cells and other cellular structures coagulates at 47°–50°. A globulin (*myoglobulin*) which coagulates at 68°C. but otherwise resembles serum globulin exists in muscle plasma.

*Fibrinogen.* This proteid, which occurs in blood plasma, very closely resembles the preceding; it differs from serum globulin in being completely precipitable by half-saturation with sodium chloride, and may thus be separated from that proteid (*Hammarsten, Pf. 19, 563*). It is precipitable by a stream of carbonic acid, but it is necessary to dilute the plasma with at least 20 times its volume of water before precipitation occurs, whereas serum globulin is precipitated when the dilution is less. It is coagulated by heat at 56°C. The heat coagulum is a very sticky one; the low temperature at which fibrinogen coagulates forms the basis of a method for esti-

imating it quantitatively: the coagulated proteid formed from the fibrinogen at 56°C. is collected on a weighed filter, washed with distilled water and alcohol, dried at 110°C., and finally weighed, ignited, and the amount of ash deducted (*Fredericq*). Under the influence of the fibrin ferment, fibrinogen is converted into fibrin; it is due to this change that blood coagulates when drawn, the fibrin entangling the blood corpuscles to form the clot. The term fibrinogen has been recently extended by *Wooldridge* to other ill-defined proteid substances which he considers to be precursors of fibrin. These are probably nucleo-albumins mixed with lecithin. For latest views on blood coagulation with references see *Halliburton (J. Physiol. 13, 829; Goulstonian Lecture No. 3, Brit. Med. J. March 1893)*.

*Plasmine.* The term 'plasmine' was given by *Denis (Mémoire sur le Sang, Paris, 1859)* to the precipitate produced by saturating blood plasma with common salt; this has since been shown to consist of the two proteids, fibrinogen and serum globulin; serino was the name given to the proteid left in solution, or, as it is now called, serum albumin.

*Myosin.* This is the proteid which is formed after the death of muscle; the muscle plasma separates into a clot composed of myosin, and muscle serum, as blood plasma separates into fibrin and blood serum. This produces a stiffening of the muscles called *rigor mortis*. The name given to the proteid precursor of myosin in the living muscle is *myosinogen*. The clot of myosin formed by diluting with water a saline extract of flesh is not so coherent as that of fibrin; it is readily soluble in 10 p.c. sodium chloride solution, from which it is precipitable by saturation with that salt or with magnesium sulphate; it forms a heat coagulum in such a solution at 56°C. Myosin is converted with great readiness into acid albumin or syntonin by weak hydrochloric acid; *A. Danilewsky* regards the compound so formed as being not ordinary syntonin but a combination of HCl with myosin, from which by suitable treatment myosin is recoverable. After long-continued dialysis, myosin can be freed from salts, and is thus rendered exceedingly insoluble, both in saline solutions and in dilute hydrochloric acid (*A. Danilewsky, H. 5, 158; Halliburton, Journ. of Physiology, 8, 136*). (See also *Muscle*.)

*Vitellin.* A proteid present in yolk of egg, which, although it resembles globulins in certain particulars, differs from them in not being precipitable by saturation with sodium chloride. Solutions coagulate at 70°–75°C. It is prepared by treating the yolk of hen's egg with ether, by which reagent most of the fatty and colouring matters are dissolved; vitellin remains undissolved as a white granular substance, which is insoluble in water, but readily soluble in dilute saline solutions. Nuclein appears to be united closely to, and may be obtained from, vitellin.

*Crystallin.* This was once called globulin, but that term has been extended to the whole group. It is obtained from the crystalline lens of the eye, composing, according to *Berzelius*, 85.9 p.c. of that structure. Its saline solutions become opalescent at 73°, but a coagulum is not deposited till 93°C. is reached. According to

**Lehmann** (*Physiol. Chem.* 1, 566) the formation of a heat coagulum is accompanied by the development of an acid instead of an alkaline reaction, as is the case with other proteids; he accounts for this by supposing that crystallin is united to ammonio-sodic phosphate, which, on the application of heat, is resolved into ammonia and acid phosphate of soda. Valenciennes and Fremy (*C. R.* 44, 1122) state that other proteids are found in the lens, and have given the name phacolin to one in that of fishes (v. also Béchamp, *C. R.* 90, 1255).

**Hæmoglobin.** When a solution of hæmoglobin, the red pigment of the blood, is heated, the liquid becomes turbid, and a coagulum of a reddish-brown colour separates out between 70° and 80°C. Heat decomposes the hæmoglobin into two substances insoluble in water, one coagulated proteid, the other a colouring matter, hæmatin, which contains all the iron of the hæmoglobin. A similar decomposition occurs when hæmoglobin is acted on by strong acids or alkalis, or by excess of alcohol. Preyer described the proteid substance under the term *globin*, which is insoluble in water, and which swells in solutions of sodium chloride and sodium hydrate without dissolving. Kühne concludes from the action of reagents that a mixture of proteids rather than a single proteid results from the decomposition of hæmoglobin; these would, however, seem to belong to the globulin class from the fact that hæmoglobin is precipitable from its solutions by saturation with such neutral salts as precipitate other globulins, and also by a stream of carbonic acid (v. art. HÆMOGLOBIN).

**Hæmocyanin.** This is a proteid associated with a colouring matter which takes the place of hæmoglobin as an oxygen-carrier in the blood of certain crustacea, arachnida, gastropoda, and cephalopoda. It was first described by Fredricq in the blood of the octopus; the blood which comes to the gills being colourless, and that leaving them being blue; the blue pigment is due to a loose combination of the proteid with oxygen, which, like oxy-hæmoglobin, parts with its oxygen to the tissues. Copper takes the place of the iron of hæmoglobin in this compound. It has not been separated into a pigment and a proteid, as hæmoglobin has. It coagulates by heat at 65°, and is precipitated by saturation with neutral salts, and by dialysis like other globulins (for references see Halliburton, *Journ. of Physiol.* 6, 300; Griesbach, *Ff.* 50, 473).

### CLASS III., ALBUMINATES.

**Acid albumin.** If a small quantity of dilute acid (hydrochloric or acetic) be added to serum or egg-albumin, no precipitation occurs, but after a short time it will be found that the albumin no longer coagulates on heating, and that its dextrorotatory power is increased. The albumin has been converted into acid albumin. On carefully neutralising such a solution with weak alkali, the whole of the proteid matter is thrown down as a white precipitate, which is soluble in excess of the alkali, and may be re-precipitated by neutralisation with weak acid, and again dissolved by excess of the acid, and so on. Acid-albumin is soluble in solutions of alkaline carbonates; it is precipitated, like globulin, by

saturation with sodium chloride or magnesium sulphate.

Acid-albumin may also be formed in a similar way from any globulin; myosin, for instance, is converted into acid albumin or syntonin, as it was first termed by Liebig, when prepared from muscle. The parapeptone of Meissner, which is formed in the first stages of peptic digestion, is also identical with acid albumin.

**Alkali albumin.** If, instead of dilute acid, dilute alkali be added to an albumin or globulin, coagulation by heat is similarly prevented, and the whole of the proteid is thrown down by neutralisation, and is soluble in excess of either acid or alkali. The name alkali-albumin is given to the proteid thus altered by alkali. Like acid albumin it is soluble in solutions of alkaline carbonates, and precipitated by saturation with sodium chloride or magnesium sulphate. In the presence of alkaline phosphates it is necessary to add more acid to obtain a precipitate than if the alkaline phosphate were absent; the acid is just used to convert the alkaline into neutral phosphate. When heated with strong solution of potassium hydrate, potassium sulphide is not formed.

**Lieberkühn's jelly.** When either tribasic phosphoric acid, acetic or tartaric acids, which do not precipitate moderately concentrated solutions of albumin, is added in excess to concentrated serum or white of egg, a jelly is produced which liquefies like gelatin on heating, and again solidifies on cooling. A similar jelly is formed by adding a strong solution of potash to serum or white of egg. This substance, called Lieberkühn's jelly, is regarded as a variety of acid or alkali albumin respectively; it is soluble with difficulty in water; the aqueous solution remains, however, clear when boiled, and is precipitated by neutralisation.

**Compounds of albumin with acids.** On account of the present uncertain state of our knowledge concerning the constitution of the proteids, the statements concerning compounds which have been described of albumin with various acids must be received with caution, as is also the case with metallic albuminates (see *Egg albumin*).

**Trinitro-albumin**  $C_{12}H_{103}(NO_2)_3N_1SO_2$  is prepared by triturating or shaking dried and powdered albumin with 14 or 15 times its weight of nitric acid ( $HNO_3$ ); a gelatinous mass is the result, and on pouring this into water the insoluble light-yellow tinted compound separates out. If the gelatinous mass be left to itself at a temperature below 10°, a small quantity of nitrogen tetroxide is given off, and a solution formed which, when diluted with water, deposits a dark-yellow tasteless *hydroxytrinitro-albumin*,  $C_{12}H_{100}(NO_2)_3N_1(OH)_2(SO_2OH)_2$ . Both these compounds dissolve without alteration in dilute alkalis, from which solution they are precipitated in yellow flocculi on addition of acid (O. Loew, *J. pr.* [2] 5, 433). If, instead of using nitric acid, a mixture of concentrated nitric and sulphuric acids be employed, a bitter yellow powder, insoluble in water, alcohol, or dilute acids, but soluble in dilute alkalis, is obtained which is called *hexnitro-albumin sulphonic acid*,  $C_{12}H_{101}(NO_2)_6(SO_2OH)N_1SO_2$ ; on treating this with ammonium sulphide, *hexamido-albumin*

**sulphonic acid**  $C_{27}H_{48}(NH_2)(SO_3OH)N_2SO_{22}$  is formed; this is decomposed by strong alkalis with evolution of ammonia, and by nitric acid with evolution of red fumes. It is insoluble in dilute acids, but readily dissolves in concentrated ones (O. Loew, *J. pr.* [2] 3, 180).

Gelatinous compounds of albumin with acids are prepared by leaving it twenty-four hours in a parchment paper dialyser and a dilute acid in the outer vessel. For a quantity of albumin represented by Lieberkühn's formula,  $C_{27}H_{48}N_2SO_{22}$ , the compounds contain 2 mols. nitric, 2 mols. hydrochloric, 1 mol. sulphuric, and  $1\frac{1}{2}$  mols. phosphoric acid (G. S. Johnson, *C. J.* 27, 784).

**Casein and Caseinogen.** Caseinogen is the chief proteid in milk. By the action of rennet it is converted into a curd called casein. Caseinogen is thrown down by the addition of acetic or mineral acids, especially if the milk be first diluted; this precipitate when freed from fats is insoluble in water, soluble in dilute acids or alkalis (and alkaline carbonates), and re-precipitable by acidulation. It may also be prepared from milk by saturating it with magnesium sulphate, followed by washing the precipitate with saturated solution of that salt till the washings contain no albumin, and then re-dissolving the precipitated caseinogen by adding water. The salt still adherent to the precipitate enables it to dissolve; the fat remains undissolved on the filter. Such a neutral solution of caseinogen becomes cloudy on heating, and the cloudiness disappears on cooling if the heating has not lasted too long. Lubavin states that caseinogen differs from alkali albumin in the following particulars: (1) when caseinogen is treated with caustic potash potassium sulphide is produced; (2) on digestion with artificial gastric juice, caseinogen yields a substance containing phosphorus, whereas an albuminate can be prepared from white of egg which contains no phosphorus (Lubavin, *Hoppe-Seyler's Med. Chem. Untersuch.* 1871, 468). C. Wurster (*B.* 20, 263) states that when hydrogen peroxide is passed through a solution of egg albumin in the presence of sodium chloride and an acid (lactic, acetic, phosphoric, or sulphuric) a proteid insoluble in water is thrown down, which he states to be a mixture of gelatinous acid albumin with a large quantity of proteid similar to caseinogen; he further supposes that hydrogen peroxide plays an important rôle in the living tissues of the body, and that the caseinogen of milk may be produced from the proteids of the blood by a similar means. The precipitate produced by adding ether to yolk of egg is also stated to have properties similar to caseinogen (Bopp, *A.* 79, 16).

Most of the older writers use the word casein to include both it and caseinogen. Different varieties of casein have been described by different observers; Berzelius, Braconnot, and others described *soluble casein*, soluble in water, and *insoluble casein*, insoluble in water (v. also Bopp, *l.c.*). The soluble casein probably consisted of the other proteids present in milk in addition to casein. More recently the view has, however, been again advanced that the only proteid in milk is casein; and that the apparent presence of albumin and other proteids is due to the action of reagents or ferments (Duclaux, *C. R.* 98, 378, 438, 526;

E. Pfeiffer, *Maly's Jahrb.* 14, 177). H. Struve (*J. pr.* 29, 70, 110) distinguishes between casein which forms the envelopes of the fat globules, and that which exists in solution in the milk; both, however, have the same properties. A. Danilewsky (*H. T.* 433) states that casein can be separated into *caseo-protalbin*, soluble in hot 50 p.c. alcohol, and *caseo-albumin*, insoluble in that reagent. Hammarsten (*H. T.* 227) has, however, shown that this behaviour of casein depends in part upon its content of calcium phosphate, the presence of which impurity depends upon the use of hydrochloric acid in the precipitation of the casein, which acid does not favour the removal of the salt as well as acetic acid. Hammarsten, moreover, showed by elementary analysis that casein is a single body; this has been confirmed by Chittenden and Painter (*Studies from the Lab. of Physiol. Chem.*, Yale Univ. 2, 156). The two last-named observers obtain the following as the percentage composition of casein: C, 53.30; H, 7.07; N, 15.91; S, 0.82; P, 0.87; O, 22.03. Hammarsten (*H. T.* 269) and Ritt-hausen (*Maly's Jahrb.* 1873, 28) have also published elementary analyses of casein.

It is owing to the presence of caseinogen that when rennet is added to milk a curd is produced, which is composed of the clotted casein and entangled fat globules; the whey or liquid residue contains the sugar, albumin, and salts of the milk. The spontaneous coagulation that sometimes occurs in milk is due either to the precipitation of caseinogen by lactic acid formed from lactose by fermentation, or to aerobic organisms which act like rennet. The coagulation that occurs when milk is boiled is due, not to the casein, but to the albumin in the milk. The ferment coagulation is a process which is entirely different from the precipitation by acid. A solution of pure caseinogen in dilute alkali will not coagulate on the addition of rennet; if, however, a small quantity of calcium phosphate or chloride be added, coagulation readily occurs. If caseinogen, precipitated by acetic acid, be well washed with water till the reaction is nearly neutral, and then neutralised with solid calcium carbonate, a pasty mass is formed which, on the addition of rennet thereto, sets into a solid clot; but here again if the caseinogen has been washed free from calcium phosphate rennet has no such action. This dependence of the rennet coagulation on the presence of earthy phosphate has been worked out by Hammarsten. The ferment causes the change from caseinogen to casein. The lime salt combines with the latter and precipitates it. Hammarsten showed that on the coagulation of caseinogen by rennet a whey albumin easily soluble in water is formed in addition to the clot of casein. Soxhlet (*J. pr.* [2] 6, 1) states that alkaline solution of artificially prepared alkali albumin also coagulates on the addition of rennet, but this statement has not been confirmed. Metacasein is a name given to an early stage of the action of rennet and pancreatic juice on caseinogen. It coagulates by heat (Roberts, *Proc. Roy. Soc.* 1881; Edkins, *Journ. Physiol.* 12, 193).

Casein in the milk of different animals is stated by Simon to vary slightly; thus human casein is yellowish-white, and very friable; it is incompletely precipitated from its aqueous solu-

tion by alkali or by acetic acid. Casein from cow's milk is less soluble in water, and becomes viscid and horny on drying. Canine milk gives a casein which does not become viscid and horny when dried, and is less soluble in water. Human casein is much more easily digested than that of cow's milk, which is more viscid, and sets into a more solid clot under the influence of the rennet ferment of the gastric juice. For recent papers on casein see Ringer, *Journ. Physiol.* 11, 464; 12, 164; Halliburton, 11, 459; Sebelien, 12, 95; Hewlett, 13, 798.

**CLASS IV., PROTEOSES.**—Under the name proteose it is convenient to include the large number of products which are intermediate in the formation of peptones from other proteids. Similar substances are formed by the action of both the peptic and tryptic ferment; those formed from fibrin or egg albumin have received the name of albumose; from globulin, globulose; from casein, caseose; from vitellin, vitellose, &c. These various substances resemble each other in their general reactions, and differ from one another in origin, slightly in percentage composition, and in a few minor reactions. The albumoses are those which have been most studied. It will be sufficient here to describe the properties of the varieties of albumose. The globuloses, vitelloses, &c., are divided into similar varieties, with corresponding prefixes.

The properties of these substances have been chiefly worked out by Kühne and Chittenden. The names first given to them were propeptone (Kühne) and a peptone (Meissner). Kühne then adopted the name albumose, and subdivided the albumoses into hemi-albumoses, those which are converted into hemi-peptones, and anti-albumoses, those which are converted into anti-peptones. Ampho-albumose is a term which includes both hemi- and anti-varieties.

The following are the chief albumoses:

(i.) Proto-albumose, soluble in distilled water and weak saline solutions, partly precipitated by saturating its acidified solutions with sodium chloride. It is also precipitated by mercuric chloride and by copper sulphate.

(ii.) Hetero-albumose, insoluble in distilled water, soluble in weak saline solutions, and completely precipitated therefrom either by dialysing out the salt or by saturation with sodium chloride. It is precipitable by mercuric chloride only in acid solutions; it is precipitated by copper sulphate. By heating its saline solutions a cloudiness is produced, which is not caused by the formation of coagulated proteid, since it readily disappears on the addition of weak acid or alkali. By the action of alcohol hetero-albumose is partially converted into an insoluble product (dys-albumose).

(iii.) Deutero-albumose. This is the albumose most nearly allied to peptone. It is soluble in distilled water, and in saline solutions; it is not precipitated by saturation with sodium chloride. It is precipitable by nitric acid only in the presence of excess of salt, and then does not dissolve so readily on heating as in the case of the other albumoses. It is precipitable by mercuric chloride, but not by copper sulphate. It can be separated from peptones by saturation with ammonium sulphate, which precipitates

deutero-albumose but not peptones. For latest work on this see Kühne, *Z. B.* 29, 1.

The above reactions are those in which the albumoses differ from one another; they resemble one another in their characteristic behaviour with nitric acid (already described), and in giving the biuret reaction. Neumeister says that in the formation of peptones from albumin, in the first stage of digestion, proto-albumose (chiefly a hemi-product), hetero-albumose, and anti-albumid (an insoluble product only partially further changed, and that into anti-peptone) are formed. Deutero-albumose is in all cases an intermediate product between these and the final peptones.

The following are the chief papers published in reference to this subject. On albumoses: Kühne and Chittenden, *Z. B.* 20, 11; H. Neumeister, *ibid.* 23, 381; Chittenden and Bolton, *Studies from the Physiol. Lab., Yale Univ.* 2, 126. On globuloses: Kühne and Chittenden, *Z. B.* 22, 409. On vitelloses: Neumeister, *ibid.* 23, 402. On caseoses: Chittenden and Painter, *Studies from the Physiol. Lab., Yale Univ.* 2, 156. On the digestion of casein: H. Thierfelder, *H.* 10, 677. On benzoylated ethers of the albumoses: Schrötter, *B.* 22, 1950.

**CLASS V., PEPTONES.**—The general reactions of these substances and of their chief varieties, hemi- and anti-peptone, have been already described. It is only since the introduction of the method of separating them from other proteids by saturating a solution containing such a mixture with ammonium sulphate that they have been obtained free from proteoses. Most of the peptones of commerce consist almost entirely of proteoses. Peptones have also been described as occurring in milk, and in certain animal and vegetable tissues, whereas these proteids are in reality proteoses artificially formed during manipulation. Certain properties previously ascribed to peptones, e.g. a power of preventing blood from coagulating after intravenous injection, are now known to be due to proteoses.

When peptones are formed artificially a bitter taste is developed; what this is due to is unknown. Pure peptone has a meaty or cheesy taste; the albumoses are also free from bitterness. It is exceedingly difficult to dry pure peptone, and when dry it hisses and froths, with evolution of heat on the addition of water.

Anti-peptone—and the same appears to be true of other anti-products of digestion (e.g. anti-albumid)—do not only not yield leucine and tyrosine on further pancreatic digestion, but appear not to contain the tyrosine radicle; they do not give Millon's reaction, and do not yield tyrosine on boiling with sulphuric acid.

(For the most recent paper on peptones, methods of purification, and ultimate analysis, see Kühne and Chittenden, *Z. B.* 22, 423.)

#### CLASS VI., INSOLUBLE PROTEIDS.

**Fibrin.** This is the proteid formed from fibrinogen, probably under the influence of a ferment derived from the white corpuscles of the blood. It is owing to its formation that blood clots after withdrawal from the body (see Blood). It may be prepared pure by washing the clot free from corpuscles by a stream of water, or better, by allowing the plasma freed from corpuscles to coagulate, and then it is

washed free from other proteids by water. It is a white elastic solid, usually exhibiting fibrillation under a high magnifying-power. It is insoluble in water, partially soluble in dilute saline solutions, the proteid which goes into solution having the properties of serum globulin. Fibrin possesses the power of liberating oxygen from solutions of hydrogen peroxide. Fibrin swells up in cold weak hydrochloric acid (0.1 p.c.); it dissolves, forming acid albumin, on heating it with weak hydrochloric acid. It is readily digested by pepsin or trypsin, yielding albumoses and peptones. Hasebroek (*l.c.* 11, 348) and A. Herrmann (*ibid.* 11, 508) state that a first product in the digestion of fibrin is a substance with many of the properties of fibrinogen. (For elementary analyses and varieties of fibrin see Hammarsten, *Pf.* 22, 484; 80, 437. See also *Fibrinogen*.)

**Coagulated proteid.** This is proteid converted by heat or alcohol into a coagulum. It is insoluble in water or dilute acids or alkalis; it is, however, like fibrin, readily digestible by proteolytic ferments.

**Lardacein** (so-called amyloid or albuminoid substance). This is formed in the disease known as waxy degeneration, the cells of the liver, spleen, and other organs being replaced by this substance. It is coloured brownish-red by iodine, hence the name amyloid (Virchow). Kekulé and Schmidt showed that it was a proteid. It is insoluble, like coagulated proteid, and it has been usually stated that it is not dissolved by gastric juice. Kostjurina (*C. C.* 1887, 120) finds, however, that it is soluble in pepsin solution acidified with hydrochloric acid.

The vegetable proteids have the same general reactions, and may be divided into the same classes as the animal proteids. Their percentage composition is also approximately the same, but varies with individual members of the group, as is the case with the animal proteids. Leucine, tyrosine, asparagine, and other amides are found in plants, which may perhaps be stages in the formation of proteids from the union of inorganic nitrogen with certain non-nitrogenous compounds in the plant tissues (*C. O. Müller, L. V.* 1886, 326). Various observers have found in vegetable tissues a crystallisable proteid, often spoken of as an albumin, but which has since been shown to consist of a globulin (vitellin). These crystals were first observed by Hartig (*Botan. Zeitung*, 1885, 881). Maschke obtained crystals from *Paranits* by extracting them with water at 50°; the crystals formed on evaporating this extract at the same temperature (*J. pr.* 74, 436). Similar crystals have been obtained by Schmiedeberg (*H. 1*, 205), by Drechsel (*J. pr.* [2] 19, 331), Ritthausen (*J. pr.* 131, 481). G. Grüber obtained octahedral crystals from pumpkin seeds and castor-oil seeds by cooling to 7° a sodium chloride extract of the seeds made at 70° (*J. pr.* 131, 105). The aleurone grains of plants have been investigated by S. H. Vines (*Pr.* 30, 387; 31, 62); in the peony, castor-oil plant, blue lupin, and many other plants. Vines found that the grains are either wholly or partially composed of proteids, and classifies them according to whether (1) they are soluble in water, in which case they consist of vegetable peptone or hemi-albumose, (2) soluble in 10 p.c. sodium chloride solution, and (3) partially soluble in 10 p.c. sodium chloride

solution. In the two latter cases globulins and albumins are also present. For recent work on crystallised vegetable proteids see Osborne, *A.M.* 14, No. 8.

**CLASS I. VEGETABLE ALBUMINS.**—In addition to the crystalline body just described, the position of which in our classification is properly in the next group, there are in vegetable juices true albumins. These have been prepared and analysed from rye by Jones (*A.* 40, 66), from wheat flour by Dumas and Cahours (*A. Ch.* [3] vi), by Boussingault (*ibid.* [2] 63, 225), from potatoes by Rüling (*A.* 58, 306), in the latex of several caoutchouc-yielding plants by J. R. Green (*Pr.* 40, 28), and in papaw juice by Martin (*J. Physiol.* 6, 336). Such albumins are coagulated by heat at about 70°, and are not precipitated by saturation with sodium chloride, magnesium sulphate, nor by acetic acid. The myrosin of mustard seeds also resembles vegetable albumin, and myco-protein from yeast and bacteria is also stated to be an albumin (Schaffner, *J. pr.* 131, 303).

**CLASS II. VEGETABLE GLOBULINS.**—These were first described by Vines (*l.c.*), and have since been classified by Martin (*Proc. Physiol. Soc.* 1887, 8), who has found them in the flour of wheat, rye, and barley, in papaw juice, and in the seeds of *Abrus precatorius* (jequirity). He divides them into two classes: vegetable myosins and vegetable paraglobulins. The myosins coagulate at 55°–60°, are precipitated by dialysing the salt away from their solutions; but this precipitate is no longer a globulin, being insoluble in saline solutions. It has the properties of an albuminate, i.e. soluble in weak acid or alkali and precipitated by neutralisation. A similar transformation occurs when a solution of the myosin, especially a dilute solution, is placed in an incubator at 35°–40° for twelve to eighteen hours. The vegetable paraglobulins coagulate at 70°–75°C., and are not transformed into albuminates, either by dialysis or by a long exposure to a temperature of 35°–40°. This classification does not include *plant vitellin* (phytovitellin), the crystalline form of which has been already alluded to. The crystals are membraneless, doubly refracting, and the proteid of which they consist has all the reactions of vitellin prepared from yolk of egg. This vitellin was found to be free from nuclein and lecithin, and may be regarded as the purest globulin yet known. Elementary analysis gave C 62.43, H 7.12, N 18.1, S 0.55 p.c. (For further analyses of vegetable proteids see Barbieri, *J. pr.* 126, 114.)

**CLASS III. VEGETABLE ALBUMINATES.**—Legumin and conglutin. Legumin, or vegetable casein, was discovered by Einhof in 1805, and called by him *végéto-animale* (*N. allgem. J. D. Ch. v.*; A. Gehlen, vi. 126, 548), in peas, beans, and lentils. Proust, H. Vogel, Boullay, Braconnot, and Liebig considered it to be identical with the casein of milk. Dumas and Cahours found that it contained less carbon and more nitrogen than casein (Gerhardt, *Traité*, 4, 491). The composition and properties of this proteid have been more recently studied by Ritthausen. He prepared it by extracting pulverised peas, beans, lentils, and vetches with dilute alkali, precipitating the strained liquid

with acetic acid, washing the precipitate with alcohol on a filter, and finally drying over sulphuric acid. It dissolves both in cold and boiling water; on analysis the following percentages were obtained: From peas, lentils, vetches, and field beans—C 51.48; H 7.02; N 16.77; O 24.32; S 0.40. From garden beans—C 51.48; H 6.92; N 41.71; O 26.35; S 0.45. Treated with sulphuric acid it yields leucine, tyrosine, glutamic, and aspartic acids. The legumin of almonds and lupines, called by Ritthausen conglutin, is richer in nitrogen, more glutinous, and more soluble in acetic acid (Ritthausen, *J. pr.* 103; 65, 78, 193, 273; [2] 26, several papers; *Z.* [2] iv. 528, 541; vi. 126; *Gm.* xviii. 427, 437). Legumin differing slightly in properties and composition has been prepared from many other sources.

In spite, however, of the vast amount of work which has been done on this subject, and which is only briefly alluded to in the foregoing paragraph, the existence of this substance is now pretty generally denied. Fresh seeds or vegetable tissues and juices contain no proteids of the casein or albuminate group, and all the substances hitherto designated plant casein are artificial products produced by the alkali used to extract them from the various globulins and albumins which exist there normally (Hoppe-Seyler, *Physiol. Chemie*, Theil i. 75). Although Ritthausen defends his views (*C. C.* 1877, 567, 586) on the ground chiefly of the concordance of numerous elementary analyses, the recent work of Vines, Green, and Martin confirms Hoppe-Seyler's statement. For proteids of oats see Osborne, *Am.* 13, 327, 385; 14, 212; of maize, Osborne a. Chittenden, *ibid.* 13, 453, 529; 14, 20; of flax, Osborne, *ibid.* 14, No. 8.

CLASS IV.—VEGETABLE PROTEOSES.—These were first described by Vines (*l.c.*) in aleurone grains, and spoken of as hemi-albumose by him. They were previously regarded as peptones. Martin (*J. Physiol.* 6, 336) has given the name phytalbumose to these substances. In papaw juice he found two phytalbumoses: *a* - phytalbumose, with which the ferment papain is associated; this resembles the proto-albumose of Kühne a. Chittenden, but differs from it in the fact that copper sulphate and saturation with sodium chloride do not precipitate it; *B*-phytalbumose, which resembles hetero-albumose, except that it is not precipitated by dialysing out the salts from its solutions, nor by copper sulphate, nor by mercuric chloride. Green (*Pr.* 40, 28) has described an albumose in latex; and Martin has found another albumose—insoluble phytalbumose—in wheat flour (*Brit. Med. Jour.* 1886, 2, 104; see also under GLUTEN).

CLASS V.—VEGETABLE PEPTONES.—True peptone does not apparently exist as such in vegetable tissue; as the result of peptic or pancreatic digestion, however, peptones are formed with intermediate products (proteoses), as in the case of animal proteids. Some, moreover, are further acted on yielding leucine and tyrosine. It is interesting to notice that in the digestion of the proteids of papaw juice by papain, a proteolytic ferment present in that juice, no true peptones, but only phytalbumoses, are formed. Papain, however, which acts like trypsin best in

an alkaline medium, forms true peptones with animal proteids (Martin, *J. Physiol.* 5, 213; 6, 336). For ferments in pineapple juice see Chittenden, *Trans. Connecticut Acad.* 8, 1. It appears probable that such ferments are widespread in the vegetable kingdom to convert the proteid of the cotyledons into peptone-like substances, and so render it available for food in the growing plant.

CLASS VI.—INSOLUBLE VEGETABLE PROTEIDS.—**Gluten.** This is the most important of the vegetable proteids which falls under this head. When wheat flour is made into a paste its stickiness is due to the presence of gluten, which can be obtained free from starch by washing the paste with water; this is most conveniently done by kneading the paste in a muslin bag under running water. Gluten is tenacious, almost tasteless, of a light brownish-grey colour; on being burnt it emits the smell of burnt horn, and on destructive distillation yields the same products as animal proteids. It dissolves in strong acids and alkalis; it also dissolves, but very slowly, in 0.2 p.c. hydrochloric acid (Bouchardat, *C. R.* 14, 962). Gluten has been stated to possess amylolytic powers, converting starch first into dextrin and then into dextrose. Taddei (*Giornale fisica di Brugnattoli*, 12, 860) first showed that gluten consists of two substances—one soluble, the other insoluble in alcohol. Ritthausen called the part insoluble in alcohol vegetable fibrin, and the part soluble in alcohol, and to which the stickiness of the gluten is due, he subdivided into two substances, *mucedin* or vegetable mucin, and *gliadin* or vegetable gelatin. These are extracted with boiling alcohol of 70-80 p.c. This extract becomes turbid on cooling, and after half the alcohol has been distilled off *mucedin* is deposited in flocculi. It may be purified by redissolving it in hot alcohol, and re-precipitating by cooling. The gliadin remains in solution in cold alcohol. *Mucedin* is soluble in cold dilute acetic acid, but when precipitated from this solution by ammonia, or left in contact with or boiled with water or dilute alcohol, it is converted into an insoluble substance like fibrin. Gliadin forms a solution in alcohol which resembles varnish; on evaporating the alcohol it is obtained in a form resembling animal gelatin. It is more soluble in hot than cold water, and is precipitated by tannic acid, basic lead acetate, and mercuric chloride. The analyses of crude gluten, and of gliadin, give approximately the same percentage composition as other proteids (Ritthausen, *J. pr.* 74, 193, 384).

Gunsberg (*J. pr.* 85, 213) regards *mucedin* as consisting simply of fragments of suspended fibrin; he states that gliadin is also not a distinct proximate principle, for cold water extracts from it a brown substance containing nitrogen and sulphur, and the residue has nearly the same composition as animal gelatin. Martin (*Brit. Med. Jour.* 1886, 2, 104) has shown that gluten does not exist in flour as such, but is formed by the action of water (perhaps also by a ferment action) on the proteids pre-existent in the flour. The doctrine of a ferment action is supported by the fact that washing flour with water at a low temperature (2°C.) does not lead to the formation of gluten. Johannsen (*Ann. Agronom.* 14,

420) has advanced evidence against the ferment theory. Gluten is insoluble in cold water, and in 10 to 15 p.c. sodium chloride solution. It dissolves partially in alcohol and in boiling water. Both these extracts contain the same substance, which is an albumose (insoluble phytalbumose), and it corresponds to Ritthausen's mucedin and gliadin. The insoluble residue, which is not sticky, may still be called gluten fibrin, and it is soluble in 0.2 per cent. hydrochloric acid. The flour itself contains two proteids: (1) A myosin coagulating between 55° and 60°, precipitated by sodium chloride and magnesium sulphate; and (2) a soluble phytalbumose. Both can be extracted from flour by 10–15 p.c. sodium chloride solution. They are considered to be the precursors of gluten, according to the following scheme:

Gluten = { Gluten-fibrin—precursor: myosin  
              { Insoluble albumose—precursor: soluble albumose

The more wheat flour has been extracted with a 10 or 15 p.c. sodium chloride solution the less is the yield of gluten when it is subsequently treated with water.

The proportion of gluten in wheat flour varies considerably according to climate, soil, temperature, &c.; the best flour containing 10–11 p.c., inferior kinds 8–9 p.c. In the moist state gluten weighs about three times as much as when dry. The flours of barley, rye, and oats contain only a trace of gliadin, or albumose, as it may now be regarded; hence these flours, containing mostly gluten-fibrin or its precursor, cannot be made into such a sticky paste as can be made with wheat flour. Gliadin also does not exist in leguminous seeds; it is said to be present in the juice of the grapes and other fruits, and is held in solution there by tartaric or other vegetable acids.

**APPENDIX A.—Proteids in urine.** Normal urine contains no proteid. The chief facts concerning proteids in morbid urine are treated fully in medical works (MacMunn's *Clin. Chem. of Urine*, Halliburton's *Chem. Physiol.*), but may be here briefly summarised as follows:

When urine contains blood (which may be detected by the microscope or spectroscope) or pus (which may be also detected microscopically), it of necessity contains a certain amount of proteid derived from these contaminations. In paroxysmal hæmoglobinuria, the urine may contain hæmoglobin or methæmoglobin independently of the presence of blood corpuscles. In the various forms of Bright's disease, the unhealthy kidney allows the proteids of the blood to diffuse into the urine, the most common and abundant being serum albumin. Serum globulin is usually also present, and is recognised by the fact that saturation with magnesium sulphate in the neutralised urine precipitates it (A. Ott, *C. C.* 1886, 540). A crystalline globulin was found in urine by Paton, *Lab. Rep. R. Coll. Phys. Edin.* 4, 47.

Clinical observers do not as a rule attempt to distinguish, however, between the various forms of proteid that occur in urine, but speak of them all under the name of albumin. The most commonly applied tests for its detection are:—(1) To boil the upper part of a test tube full of urine; any cloudiness produced is then seen in contrast to the clear urine below. If any precipitate occurs it is insoluble in acetic acid, so distin-

guishing it from phosphates. If the urine is neutral or alkaline it is necessary always to acidify with acetic acid either before or after boiling, in order to obtain a precipitate. The clinical method of estimating the proteid quantitatively has been already described. (2) Nitric acid causes a precipitate in the cold. If urine contains but little proteid, it may be detected by pouring the urine on to the surface of some nitric acid in a narrow test tube, the ring of precipitate at the junction of the two liquids is then clearly seen (Heller). The difficulty of carrying nitric acid about has led to the adoption more recently of methods in which test papers saturated with various reagents, picric acid, potassio-mercuric iodide, &c., are added to the urine. A committee of the Clinical Society have recently presented a report in which the relative advantages of various methods of detecting albumin in urine are discussed (*Clin. Soc. Trans.* 19, 339). They have investigated Dr. Oliver's test papers just mentioned; Dr. Pavy's pellets of citric acid and potassium ferrocyanide; Dr. Johnson's picric acid solution; Sir W. Roberts's acid brine test; acetic acid and boiling nitric acid; and a solution of potassio-mercuric iodide with citric acid. The last named is the most delicate reagent in the list; the test papers and pellets are not so delicate but are more convenient; the picric acid test has the advantage of being also applicable for recognising (after the addition of potash) sugar as well as albumin.

Besides albumin and globulin in urine, other proteids may sometimes occur; viz. (1) egg albumin—this occurs after a very large ingestion of eggs as food; (2) Bence-Jones albumin, so called after its first observer, has been shown to be a form of hemi-albumose—it occurs in cases of osteomalacia; (3) peptones or deutero-albumose occurs in many suppurative diseases, and doubtless originates from the disintegration of pus cells; (4) casein has been stated to occur in chylous urine, but there are considerable doubts as to the accuracy of this statement; (5) mucin occurs not only in suspension in the mucus from the urinary tract, but it appears to be occasionally present dissolved in the urine—it is precipitable therefrom by acetic acid. It is probably not true mucin, but a nucleo-albumin.

**APPENDIX B.—Proteids as poisons.** For effects on blood pressure, &c., of albumoses and peptones, v. Pollitzer, *J. Physiol.* 7, 283. The poison of venomous snakes has also been shown to depend on the proteids contained therein (Weir Mitchell), and not to any alkaloid, ptomaine, or cobric acid (W. Blyth, *An.* 1, 204). Wolfenden has separated a globulin, albumin, syntonin, and albumose from the venom of the cobra and daboia; for the action of these v. *J. Physiol.* 7, 327; see also Kanthack, *ibid.* 13, 272. The poisonous principle ahrin of Abrus or Jequrity is also proteid (Martin, *Pr.* 42, 331). The subject of proteid poisons has recently risen into prominence, as it is found that the micro-organisms of many diseases produce these toxalbumoses. Koch's tuberculin owes its activity to similar substances. The poisons produced in anthrax, diphtheria, &c., are also proteid in nature. For references see Halliburton's *Chem. Physiol.* German translation; Martin, *Brit. Med. Journal*, March and April 1892. On the other hand,

certain proteids (globulins or nucleo-albumins) are protective and destroy micro-organisms. They are termed alexines by Doremberg, Buchner, and Hankin. For Hankin's most recent paper, see *Centr. Bacteriol.* 12, Nos. 22 and 23.

**APPENDIX C.—Albuminoids.** The term 'albuminoid' is still used by some synonymously with proteid; it will be here restricted to a number of substances which resemble proteids in many points, but which differ from them in others.

**Collagen.** This is the substance of which the white fibres of connective tissue are composed, and which by the action of boiling water is converted into gelatin. Collagen is prepared from tendons by Rollett's process as follows: the finely-divided tissue is soaked in water to remove proteids, and then for some days in lime water to dissolve the mucin-holding cementing substance between the fibres. The insoluble matter is washed first with water, then with weak acetic acid, and then again with water. The residue consists of collagen, mixed, however, with small quantities of elastin and nuclein. With very dilute acids or alkalis collagen swells and becomes transparent.

The organic material which composes one-third of the substance of bone consists mainly of a substance identical with collagen, and which has been termed *ossein* by some writers. The organic basis of dentine (but not of the enamel of tooth) is also collagenous.

**Gelatin.** When the white fibres are subjected to the action of boiling water, or of water heated under pressure, as in a Papin's digester, or to the long-continued action of dilute acids at the ordinary temperature, they dissolve, and the solution contains a substance called gelatin. Gelatin may be similarly prepared from bones. Isinglass is gelatin prepared from the swimming bladder of the sturgeon; an inferior kind is made from fish bones. Glue is the crude product obtained by boiling down hides, bones, &c. (v. Ure, *Dictionary of Arts, &c.*, [2] 324, 376). Pure gelatin is prepared from commercial gelatin by soaking the latter in distilled water for some days to remove salts; it is then dissolved in hot distilled water, and filtered while hot into 90 p.c. alcohol. The gelatin separates in the form of white thready masses, which can be subsequently dried. Thus prepared it contains only 0.6 p.c. of ash.

Gelatin is insoluble in cold, but soluble in hot water; on cooling the hot watery solution it sets into a jelly (gelatinises); this property is possessed by solutions as weak as 1 p.c., it is lost by prolonged boiling, or instantly by heating to 140° in sealed tubes. Gelatin is insoluble in alcohol, ether, and chloroform. Aqueous solutions are powerfully levorotatory, the rotatory power being influenced by the temperature and reaction of solution; at 30° [α]<sub>D</sub> = -130 (Hoppe-Seyler). Gelatin is not precipitated by acetic acid nor by a solution of lead acetate; it may be thus distinguished from chondrin. It is not precipitated by acetic acid and potassium ferrocyanide, nor by the majority of metallic salts which precipitate proteids. Tannic acid even in very dilute solutions precipitates it; it is on the formation of the last-named precipitate that

the conversion of hides into leather is brought about.

Schützenberger and Bourgeois ascribe to gelatin the formula  $C_{12}H_{13}N_3O_{11}$ . Hofmeister (*H.* 2, 315) finds that by heating gelatin it loses water, and is converted into collagen, which he therefore considers an anhydride of gelatin; his formula for gelatin is  $C_{10}H_{11}N_3O_{10}$ .

By the action of boiling water, gelatin loses after 25 hours its power of gelatinising, and it is split up into two peptone-like bodies, *semiglutin* (sparingly soluble in 70-80 p.c. alcohol and precipitated by platinum tetrachloride) and *hemcollin* (soluble in 70-80 p.c. alcohol, not precipitated by platinum tetrachloride). Similar substances are formed by the action of the peptic or pancreatic ferment, but ultimately true gelatin peptones (not precipitable by saturation with ammonium sulphate), leucine, glycocine, and volatile fatty acids are formed. (The foregoing account of gelatin is very largely taken from Gamgee's *Physiol. Chem.*, p. 252.) Many bacteria liquefy gelatine. On digestion of gelatin see Clittenden, *J. Physiol.* 12, 23, 84. The most recent work on the decomposition products of gelatin has been done by Schützenberger. On heating gelatin at 200° with barium hydroxide, one-fifth of the total nitrogen is converted into ammonia; carbonic and oxalic acids are also formed, these products being in the ratio of the products of decomposition of urea and oxamide. The other products are amido-acids of the acetic series, the most important being glycocine, alanine, amido-butyric acid and leucine, and acids of an homologous series  $C_nH_{2n}N_2O_3$ , the value of  $n$  varying from 8 to 10. These latter acids are difficult to isolate; at 100°-120° they are converted into anhydrides; they do not yield derivatives with acetic anhydride, but with ethyl iodide in the presence of an alkali they yield di-ethyl derivatives. The general results lead to the conclusion that gelatin is formed by the combination with elimination of water of 1 mol. urea or oxamide with 2 groups  $C_nH_{2n}N_2O_3$  and 4 groups  $C_nH_{2n}NO_2$ ,  $n$  being 2, 3, 4, or 6, with a mean value of 3.5 (v. Schützenberger a. Bourgeois, *C. R.* 82, 262; Schützenberger, *C. R.* 102, 1296). Both gelatin and albumin yield on treatment with alcoholic hydrochloric acid a diazo-compound  $C_6H_5N_3O$  (Buchner a. Curtius, *B.* 19, 850).

The question of the part played by gelatin, which is an easily-digestible substance in nutrition, is very important practically, jellies especially being given to invalids. The question was first investigated by J. Etzinger (*N. R. P.* 23, 535), and subsequently by Voit (*Z. B.* 8, 297). Voit's chief result showed that gelatin will not entirely replace proteids, but that animals rapidly waste which are fed on it alone, but, in conjunction with a certain small amount of proteid, it is capable of maintaining nitrogenous equilibrium as well as if the only nitrogenous food taken was proteid in nature. These results have been since very generally confirmed (v. S. Pollitzer, *Pf.* 87, 301). Voit distinguishes between circulating and organic albumin; gelatin can never yield the latter, but it may replace the former in so far as it prevents the conversion of organic into circulating albumin. Gelatin also diminishes the waste of fat in the body.

**Mucin.** This body forms the chief constituent of the ground substance of connective tissue, the other organic constituent being a globulin very like serum globulin. Mucin is especially abundant in the 'jelly like' tissue of the umbilical cord, and in the vitreous humour. The cement-substance of epithelia behaves similarly to microscopic reagents (especially silver nitrate, by which it is stained brown owing to a deposit of metallic silver), and is probably of the same chemical nature as the ground substance of connective tissue; both are soluble in alkalis. Mucin forms the chief constituent of mucus, and gives the sliminess to the secretion of mucous membranes. In mucus it is suspended in an alkaline exudation from the blood and mixed with the debris of epithelium cells, and a few white blood corpuscles. The mucin itself is here formed by the protoplasm of certain cells of the epithelium becoming altered, so that it becomes swollen and brightly refracting; the globule of mucin so formed is discharged, leaving a so-called goblet cell. In mucous glands, such as the submaxillary salivary gland, a very similar replacement of protoplasm by mucin (or mucigen, as it is called when inside the secreting cells) takes place. Mucin is also largely contained in the surface secretion of several invertebrate animals, e.g. the snail. Mucin is contained in submaxillary saliva; the metalbumin and paralbumin (q. v.) of ovarian cysts is a very similar substance. The substance which confers sliminess to the bile and the synovial fluid, formerly considered to be mucin, has been shown to consist of a nucleo-albumin (q. v.).

The methods of preparation of mucin from its various sources differ; from tendon (v. Bollett, *Sitz. W.* 30, 308; Löbisch, *H.* 10, 40); from submaxillary gland (Obolensky, *Pf.* 4, 336; Hammarsten, *H.* 12, 163); from bile (Gautier, *Chimie Appliquée à la Médecine*, 2, 126; Pajkull, *H.* 12, 196). Eichwald, Hammarsten, and others have prepared it from snails (*Pf.* 36, 373), and Giacosa (*H.* 7, 40) from the membranes of frog's eggs. These methods depend upon the fact that mucin is soluble in weak alkalis, e.g. lime water or dilute baryta water, and can be precipitated from this solution by acetic acid, in excess of which it is not soluble. Hammarsten finds, however, that submaxillary mucin is easily decomposed by lime water and similar weak alkaline fluids; he, therefore, uses water to extract the mucin. Hammarsten has shown that considerable differences exist in mucin according to its origin; this was previously suspected from the divergencies in elementary composition. Tendon mucin (C, 48.3; H, 6.44; N, 11.75; S, 0.81 p.c., Löbisch) and submaxillary mucin (C, 48.84; H, 6.8; N, 12.32; S, 0.8, Hammarsten) are very much alike in elementary composition, but differ in their reactions; e.g. tendon mucin is not easily decomposed by weak alkalis, nor is it so easily soluble in weak hydrochloric acid as submaxillary mucin. These forms of mucin differ still more from those obtained from *Helix pomatia*; Hammarsten, indeed, has shown that two distinct varieties of mucin, from the foot and mantle respectively, can be obtained from this snail.

Mucin gives the xanthoproteic, Millon's, and the Adamkiewicz reactions; it is precipitated,

but not rendered insoluble, by saturation with sodium chloride or magnesium sulphate, and by alcohol. It is precipitated by acetate of lead, but by no other metallic salt (except the submaxillary mucin, which is precipitated by several), it is not precipitated by tannic acid nor by boiling; acetic acid gives a characteristic stringy precipitate. Mucin yields, when boiled with strong sulphuric acid, leucine and tyrosine, and when boiled with caustic soda pyrocatechin (Obolensky). When boiled with dilute sulphuric acid for a few hours, mucin yields a reducing sugar, but one which is not capable of the alcoholic fermentation, and albumin is also formed. Landwehr regards mucin as a compound of a proteid and a non-reducing carbohydrate ( $C_{12}H_{22}O_{11}$ ) which has most of the properties of plant gum; he calls it animal gum (*Pf.* 39, 193). At one time this carbohydrate was regarded as a variety of glycogen which gave no colour with iodine (achrooglycogen).

**Met-albumin and paralbumin.** These two proteid-like substances are fairly constantly found in the fluids removed from ovarian cysts (Scherer), and occur occasionally in other cysts and in ascitic fluid also. Metalbumin is a form of mucin (pseudomucin); paralbumin differs from metalbumin by giving a precipitate when it is boiled; it is probably a mixture of pseudomucin with albumin, and can indeed be prepared by mixing these two substances. Both yield reducing sugars when boiled, and both contain animal gum (D. Hammarsten, *Maly's Jahrb.* 11, 11; Landwehr, *H.* 8, 114; *Pf.* 39, 193; Oerum, *Maly's Jahrb.* 14, 459).

**Nuclein.** This is the name given to the substance which composes the nuclei of cells. It was prepared by Lauder Brunton from the red blood corpuscles of birds and snakes; the nuclei were freed from adhering stroma and haemoglobin by repeated agitation with ether and water (*Journ. of Anat. and Physiol.* 2nd series, 3 91). Nuclein resembles mucin in its solubilities. Ploetz found, however, that it contained phosphorus (Hoppe-Seyler, *Med. Chem. Untersuchungen*, Heft 4, 460), and considered it was identical with the nuclein which Miescher separated from the nuclei of white corpuscles (*ibid.*). Miescher separated the nuclein from the other constituents of the cells by subjecting them to artificial gastric digestion, nuclein, like mucin, being indigestible by pepsin. Miescher ascribes to it the formula  $C_{12}H_{18}N_4P_2O_{10}$ . Nuclein has also been separated from the brain (Jaksch, *Pf.* 13, 469) to the amount of 0.14 p.c. (Geoghegan, *H.* 1, 330), and from the liver; it is probably present in all parts where nucleated cells occur. Miescher has also described nuclein as occurring in the yolk of hens' eggs; it has also been described in milk. A. Kossel (*H.* 10, 248) has shown that the nuclein of yolk and milk differ from that of cell nuclei in containing iron, and by not yielding guanine and hypoxanthine when decomposed at a high temperature by weak acids. Adenine  $C_5H_5N_5$  is described by Kossel as being an intermediate product between cell nuclein and hypoxanthine. Nuclein is present in vegetable cells also, and adenine can also be obtained from this. It is present in yeast (Hoppe-Seyler) and mildew; in tea leaves (Kossel), in poppy, earth nut, rape and cotton,

cake; also in palm nut, but the proportion P:N is different in the nuclein prepared from this source (Klingenberg a. A. Stutzer, *B. C.* 1883, 204). Miescher's formula for nuclein must, indeed, be received with caution; there are either several varieties of nuclein—for elementary analyses show great discrepancies—or else, as Worm Müller (*Pf.* 8, 190) supposes, it is no definite chemical individual, but the different nucleins are mixtures of an organic phosphorus compound with varying quantities of proteids. Recent work on nuclein has shown that this phosphorus compound is nucleic acid (Altmann, *Arch. f. Anat. u. Phys.* 1888, 524). For artificial nuclein made by adding phosphoric acid to albumin see Liebermann, *B.* 21, 598; Pohl, *H.* 13, 292; Malfatti, *B. d. Naturwiss. Med. Ver. Innsbruck*, 1891-2; Kossel, *Verh. physiol. Ges. Berlin*, Oct. 21, 1892. See also numerous papers by Kossel, Krüger, and others on adenine and nuclein bases in last few volumes of *H.* For iron compounds of nuclein see Bunge's *Physiol. Chem.* This hematogen is probably the normal iron-containing food. The chromatin and plastin of histologists are respectively phosphorus-rich and phosphorus-poor nucleins. For iron in the nucleus see Macallum, *P.* 49, 488.

**Nucleo-proteids. Nucleo-albumin.** E. Merck (*D. P. J.* 261, 316) calls nucleo-proteids substances which, when boiled with water under pressure or treated with acids, alkalis, or ferments, are resolved into nuclein and albumin; for instance, vitellin and casein (*v.* also Lubavin, Hoppe-Seyler, *Med. Chem. Unters.* p. 447). Hammarsten gives the name nucleo-albumin to a class of proteid-like bodies which are very like globulins, being precipitated from their solutions by saturation with sodium chloride or magnesium sulphate; they are also precipitated by acetic acid, but, unlike mucin, are soluble in excess. On gastric digestion of a clear solution, an insoluble phosphorus-containing substance, like nuclein, is formed. Many nucleo-albumins have the physical characters of mucin, and the sliminess of bile and synovia is due to such bodies (Hammarsten, *H.* 12, 173, on synovia; *Maly's Jahrsber.* 12, 1882, on bile-mucin; Pajikull, *H.* 12, 196). The chief proteid constituent of all protoplasm is nucleo-albumin (Halliburton's Goulstonian Lectures, *Brit. Med. Journ.*, March 1893). Wooldridge's tissue fibrinogens are also nucleo-albumins (for ref. see above lectures).

**Chondrin.** This is the substance obtained from cartilage by boiling; the mother substance of chondrin in the matrix of the cartilage is termed chondrigen. Hot aqueous solutions of chondrin gelatinise on cooling like those of gelatin. Aqueous solutions are precipitated by the same reagents that precipitate solutions of gelatin and of mucin. It is strongly laevorotatory; its rotatory power in solutions of different strengths has been studied by de Bary (*Med. Chem. Unters.* i. 71). Very great discrepancies exist between the results of various analyses (see table comparing analyses by Mulder, Fischer a. Bödecker, Schützenberger a. Bourgeois, and v. Mehring in Gamgee's *Physiol. Chem.* p. 270), hence considerable doubts have been entertained of its being a chemical individual. It gives the reactions both of mucin and gelatin; on being boiled with dilute acids it

yields a laevogyrate reducing sugar, called by de Bary chondriglucose (*v.* also Fischer a. Bödecker, *A.* 117, 111), but is now regarded as identical with that obtained from mucin, Landwehr considering that animal gum is contained in chondrin as in mucin (*Pf.* 39, 204, 40). Morochowitz was the first to arrive at the conclusion that chondrin is a mixture of gelatin and mucin (*Verhandl. d. naturhist. med. Vereins zu Heidelberg*, 1, Heft 5); mucin can be extracted from it with lime or laryta water, and pure gelatin is left behind. On this assumption chondrigen = collagen + mucin. It must, however, be mentioned, in opposition to this view, that Hoppe-Seyler (*J. pr.* 56, 129) and Otto (*Z.* [2] 4, 628) state that on treating chondrin with dilute sulphuric acid it yields leucine, but no tyrosine or glycosine. The most recent work on chondrin shows that it is chondroitin acid rather than mucin which is present (C. T. Möerner, *H.* 12, 396; Skand, *Arch. Physiol.* 1, 210; Krukenberg, *Z. B.* 20, 307; Schmiedeberg, *Arch. exp. Path. u. Pharm.* 1891, 355).

**Elastin.** This substance is the very insoluble material of which the elastic fibres of connective tissue are composed. It may be prepared from the *ligamentum nuchae* by boiling it with ether and alcohol to remove fatty matters, then for 36 hours with water to remove the collagen. The residue is boiled with strong acetic acid, and afterwards with concentrated caustic soda till the fibres begin to swell; it is then treated with weak acetic acid, water, and lastly for 24 hours with hydrochloric acid. The acid is removed by washing with water, and the residue has still all the characters of fresh elastic tissue, and has the following percentage composition: C, 55.45; H, 7.41; N, 16.19; O, 20.89 (Müller, *Zeit. f. Nat. Med.* 3, 10, Heft 2). For recent analyses see Chittenden, *Z. B.* 25, 363.

Elastin is not soluble in any liquid which does not decompose it. It is soluble in boiling concentrated caustic potash, in concentrated nitric and sulphuric acids. It is digestible by both pepsin and trypsin; the former ferment being the more active (A. Ewald a. W. Kühne, *Die Verdauung als histol. Methode*). Peptones are ultimately formed; there are also intermediate bodies of the nature of albumoses (Horbaczewski, *C. C.* 1885, 843). Elastin when treated with sulphuric acid yields leucine but no tyrosine.

**Keratin.** This substance replaces the protoplasm in the cells of certain epidermal structures, viz. the superficial layer of the epidermis itself, nails, horns, hoofs, feathers, and the cuticle and fibrous substance of hairs. It is prepared by successively boiling the tissue with ether, alcohol, water, and dilute acids; the insoluble residue is keratin.

Subjected to the prolonged action of water under pressure at 150°-200° it yields a turbid solution. It is also dissolved by boiling with alkalis, and on the addition of acids to this solution sulphuretted hydrogen is given off, the sulphur in keratin, which varies considerably in amount, being very loosely combined. Horn swells in dilute acetic acid, dissolves in boiling glacial acetic acid, and in nitric acid; it yields aspartic acid, volatile fatty acids, leucine and tyrosine when boiled with dilute sulphuric acid.

when burnt it gives off a characteristic smell. The following are the chief analyses that have been made (Hoppe-Seyler, *Physiol. Chem.*, Th. 1, p. 90):—

—	Hair (v. Lacer)	Nails (Mulder)	Horn (Tilanus)	Hoof (Mulder)
C	50.60	51.00	51.03	51.41
H	6.36	6.94	6.80	6.96
N	17.14	17.51	16.24	17.46
O	20.85	21.75	22.51	19.49
S	5.00	2.80	3.42	4.23

**Neurokeratin.** This is a substance which forms an irregular framework in the medullary sheath of nerve fibres, which resembles keratin in its general behaviour, but differs from it in being less easily soluble in boiling solutions of caustic potash (Ewald a. Kühne, *Verhandl. d. naturhist. med. Vereins zu Heidelberg*, vol. i. Heft 5; Kühne a. Chittenden, *Z. B.* 26, 291). This substance is interesting, as both the epidermis and the nervous system are derived from the epiblast of the embryo.

**Chitin.** This substance forms the chief constituent of the skeletal octodermal tissues of invertebrate animals, especially arthropoda. A list of situations in which it has been described is given in Gamgee's *Physiol. Chem.* p. 299; to these must be added the pen of cuttlefishes (Krukenberg), the cartilages and other mesodermal tissues of scapia and the king-crab (Halliburton, *Pr.* 88, 75). In crustacea it is often impregnated with calcareous matter, and in the odontophore of molluscs with silica. It is prepared from the wing-cases or shells by boiling them with caustic soda. The chitin remains insoluble. It may be dissolved in cold concentrated hydrochloric acid, and the solution precipitated by the addition of water. It is colourless, amorphous, insoluble in water, alcohol, ether, acetic acid, dilute mineral acids, and solutions of the alkalis. It is dissolved by concentrated mineral acids. (On the solubilities of chitin v. Krukenberg, *Z. B.* 22, 480.)

The formula for chitin is  $C_{12}H_{19}N_3O_{10}$  (Ledderhose, *H.* 2, 213; 4, 139). Berthelot (*C. R.* 47, 227) stated that it yields a fermentable sugar on boiling it with sulphuric acid; and Sandwick considered it to be an amine derivative of a carbohydrate with the formula  $N(C_{12}H_{19}O_{10})$ . Ledderhose showed, however, that the reducing substance is a nitrogenous body, glucosamine; and when chitin is heated with acids it takes up the elements of water, and yields glucosamine and acetic acid,

Glucosamine is an amido-derivative of grape sugar ( $C_6H_{12}O_6 - OH + NH_2 = C_6H_{13}NO_5$ ); it forms salts, of which the hydrochloride is formed by boiling chitin with hydrochloric acid; this is a crystalline substance soluble in water, and in solution dextrorotatory ( $\alpha_D = +70.6^\circ$ ). The pure base prepared by the action of barium hydrate on the sulphate of glucosamine crystallises from alcohol in the form of needles. It is not fermentable. (The foregoing account of elastin, keratin, and chitin is largely taken from Gamgee's *Physiol. Chem.*, which see for fuller details.)

**Skeletins.** This term is applied by Krukenberg (*Z. B.* 22, 241) to a number of nitrogenous but sulphur-free substances, including conchiolin, spongin, &c., found in the skeletal tissues of invertebrates; they are probably all like chitin amido-derivatives of carbohydrates. The substances are all very insoluble.

Conchiolin ( $C_{20}H_{18}N_2O_{11}$ ) forms the organic basis of the shells of mussels and snails. On decomposition it yields leucine, perhaps glycocine, but no tyrosine nor reducing substance. It does not give the xanthoproteic, Millon's, nor the Adamkiewicz reactions. The cementing substance between the eggs of various molluscs, whose shells and egg capsules contain conchiolin, is coloured red by heating with Millon's reagent, and contains a body allied to keratin. Cornein (from corals) ( $C_{20}H_{18}N_2O_{11}$ ) differs from conchiolin by giving a red colour with Millon's test.

Spongin, the organic basis of the common sponge, yields as decomposition products leucine and glycocine (Städeler), but no tyrosine. It does not give any of the colour reactions mentioned above; it also resembles conchiolin by yielding on digestion peptone-like substances which differ from true peptones and albumoses by not giving the three colour reactions just mentioned; they thus differ from keratin, which is not digestible.

Fibroin, the chief constituent of insects' cocoons and spiders' threads, behaves to all three tests like an ordinary proteid, and on decomposition yields leucine, glycocine, and tyrosine. Fibroin is soluble when heated in sealed tubes in glacial, acetic, and other organic acids (A. Ledow, *Maly's Jahrsbericht*, 13, 32). For silk see Weyl, *B.* 21, 1407, 1529.

**Hyalins and Hyalogenes.** The term 'hyalin' is applied to the chief constituent of the walls of hydatid cysts. Krukenberg states (*Z. B.* 22, 261) that the substance is present in the cyst wall as hyalogen, an insoluble substance which by the action of alkalis is changed into hyalin, which is easily soluble in water. Hyalogen is also converted into hyalin by heating with water (under pressure) at  $150^\circ C$ . (For elementary composition v. Lücke, *Virchow's Archiv*, 19, 189). By heating with sulphuric acid hyalin yields a sugar, probably glucose, which is dextrorotatory and capable of the alcoholic fermentation, and in this hyalin resembles mucin.

Krukenberg has extended the terms hyalogen and hyalin to other similarly related bodies obtained from various sources. The edible bird's nest has properties very like those of mucin (v. J. R. Green, *J. Physiol.* 6, 40), and is the result of the activity of certain glands described by Bernstein (*Journ. Ornithologie*, 1859, 111) as being remarkably developed in the nest-building season. Krukenberg finds that it is chiefly composed of a hyalogen (*neossine*), which yields as its hyalin, *neossidine*. *Chondrosine* is a hyalogen, obtained from the sponge *Chondrosia reniformis*. The vitreous humour from the eyes of oxen and pigs was found to contain a hyalogen, whereas the cornea did not yield one, but was found to consist chiefly of collagen, and a proteid allied to myosin. *Spirographin*, which largely composes the skeletal tissues of the worm *Spirographis* is also a hyalogen, but differs from others by yielding when acted on by alkalis

not only a hyalin, *spirographidin*, but also pyrocatechin. The halogens are not acted on by gastric juice; some are, some are not attacked by trypsin. W. D. H.

**PROTEIN v. PROTEIDS.**

**PROTEOSES v. PROTEINS.**

**PROTO-ALBUMOSE v. PROTEIDS.**

**PROTocatechuic Acid**  $C_8H_6O_4$ , i.e.  $C_8H_5(OH)_2.CO_2H$  [4:3:1]. Mol. w. 154. [199°] (Hlasiwetz); [194°] (Barth a. Schmidt, B. 12, 1265). S. 1.9 at 14°; 10 at 60° (Tiemann a. Nagai, B. 10, 211). Occurs in the fruit of *Illium religiosum* (Eykmann, R. T. C. 4, 47).

**Formation.**—1. By potash-fusion from piperico acid (Strecker, A. 118, 280), catechin (Kraut, A. 128, 285), maelurin (Hlasiwetz a. Pfandler, A. 127, 351), guaiac resin (Hlasiwetz a. Barth, A. 130, 346), kino (Stenhouse, C. J. 28, 6), caffeic acid (Hlasiwetz, A. 142, 219), cinchona-red (Rembold, A. 143, 273), assafoetida (Hlasiwetz a. Barth, A. 138, 61), angelica-resin (Brünner, N. R. P. 24, 641), many other resins, the methyl-derivative of sulpho-p-oxy-benzoic acid (Malin, A. 152, 109), sulpho-m- and sulpho-p-oxy-benzoic acids (Barth, C. J. 24, 829), and iodo-p-oxy-benzoic aldehyde (Tiemann a. Herzfeld, B. 10, 213).—2. By heating piperonylic acid with HClAq at 150° (Fittig a. Remsen, A. 159, 129).—3. By the action of Br and water on quinic acid (Hesse, A. 112, 52; 122, 221; Fittig, A. 168, 111).—4. By heating pyrocatechin with water and ammonium carbonate at 140° (Miller, C. J. 41, 400).

**Properties.**—Tufts of monoclinic needles (containing aq), sol. water, alcohol, and ether, nearly insol. boiling benzene. FeCl<sub>3</sub> colours its aqueous solution bluish-green, the colour changing to red on addition of alkalis. FeSO<sub>4</sub> colours solutions of its salts violet. Pb(OAc)<sub>2</sub> gives a pp., sol. acetic acid. Crystallises with p-oxy-benzoic acid as  $(C_8H_5O_4)_2.C_8H_5O_4.2aq$ , which yields  $PbC_8H_5O_4.2aq$  (Hlasiwetz, A. 134, 276). Reduces aqueous AgNO<sub>3</sub> on heating or on adding NH<sub>4</sub>Aq. Does not reduce Fehling's solution.

**Reactions.**—1. Split up by dry distillation into CO<sub>2</sub> and pyrocatechin.—2. Soda-fusion gives 55 p.c. of the theoretical amount of pyrocatechin.—3. Bromine in the cold forms bromo-protocatechuic acid. Br at 100° yields tetra-bromo-pyrocatechin.—4. N<sub>2</sub>O<sub>4</sub> passed into the ethereal solution forms oxalic acid (16.5 p.c.), carboxy-tartronic acid (10 p.c.), di-nitro-di-oxy-quinone (5 p.c.), trinitrophenol (4 p.c.), (a)-di-nitro-phenol [114°] (3.5 p.c.), and nitro-p-oxy-benzoic acid (1 p.c.) (Gruber, B. 12, 514).—5. H<sub>2</sub>SO<sub>4</sub> (25 pts.) at 140° forms a very small quantity of tetra-oxy-anthraquinone (rufopin) (Nölting, Bl. [2] 37, 395).—6. Heating with As<sub>2</sub>O<sub>3</sub> at 160° or exposing a solution in Na<sub>2</sub>CO<sub>3</sub>Aq to the air forms catellagic acid C<sub>8</sub>H<sub>4</sub>O<sub>7</sub>,? which resembles ellagic acid and forms an orange solution in nitric acid.

**Salts.**—BaA', 5aq.—Ba<sub>2</sub>(C<sub>8</sub>H<sub>4</sub>O<sub>6</sub>)<sub>2</sub> (dried at 130°) (Barth, A. 142, 246).—CaA', 4aq.—CaA', 3aq.—Pb<sub>2</sub>A'<sub>2</sub>O<sub>2</sub>.—PbA', 2aq.

**Acetyl derivative**  $C_8H_5(OAc)_2.CO_2H$ . [158°]. Crystals (Herzig, M. 6, 872).

**Methyl ether MeA'.** [134.5°]. Needles.

**Ethyl ether EtA'.** [134° cor.]. Prisms (Matamoto, B. 11, 129).

**m-Methyl derivative**

$C_8H_5(OH)(OMe).CO_2H$  [4:3:1]. **Vanillic acid.** [207°]. S. 12 at 14°; 2.5 at 100°. **Formation** (Tiemann, B. 8, 509, 1123; 9, 52, 419; 10, 59, 202; 11, 122).—1. By exposing moist powdered vanillin to the air.—2. By oxidising coniferin with dilute KMnO<sub>4</sub>.—3. From its acetyl derivative, which is got by the action of KMnO<sub>4</sub> on acetyl-eugenol, acetyl-ferulic acid, and acetyl-crocosol.—4. Together with isovanillic acid by heating  $C_8H_5(OMe)_2.CO_2H$  with HClAq at 140°. **Properties.**—Needles (from water), v. s. sol. alcohol, m. sol. ether. Has no smell. May be sublimed. Gives no colour with FeCl<sub>3</sub>. **Reactions.**—1. Split up by HClAq (S.G. 1.1) at 150° into protocatechuic acid and MeI.—2. Potash-fusion yields protocatechuic acid.—3. By heating with MeI (2 mols.) and KOH (2 mols.) it is converted into  $C_8H_5(OMe)_2.CO_2Me$ .—4. Yields guaiacol on distillation with lime.—5. The Ca salt yields vanillin on distilling with calcium formate.

**Methyl ether of the m-Methyl derivative MeA'.** [63°]. (286°).

**Ethyl ether of the m-Methyl derivative EtA'.** [44°]. (292°).

**Acetyl derivative of the m-Methyl derivative**  $C_8H_5(OAc)(OMe).CO_2H$ . [142°]. Needles (from dilute alcohol).

**Benzoyl derivative of the m-Methyl derivative.** [178°] (Tiemann, B. 15, 2068).

**p-Methyl derivative**

$C_8H_5(OMe)(OH).CO_2H$  [4:3:1]. **Isovanillic acid.** [250°]. S. 0.6 at 15°; .7 at 100°. Formed with other products by heating protocatechuic acid with MeI and KOH at 150°. Got also by heating hemipic acid with HClAq (Matthiessen a. Foster, A. Suppl. 2, 878), and, together with vanillic acid, by digesting  $C_8H_5(OMe)_2.CO_2H$  with dilute HClAq at 140° (Tiemann). The acetyl derivative is got by oxidation of the acetyl derivative of isoferulic acid (hesperetic acid) by KMnO<sub>4</sub> (Tiemann a. Will, B. 14, 903), and likewise by oxidation of the acetyl derivative of betelphenol  $C_8H_5(OMe)(OH).C_8H_5$  [4:3:1] (Bertram a. Gilde-meister, J. pr. [2] 39, 349). Prisms, v. sol. alcohol and ether. May be sublimed. Its aqueous solution is not coloured by FeCl<sub>3</sub>. Yields a nitro-derivative [173°] and an **acetyl derivative**  $C_8H_5(OMe)(OAc).CO_2H$  [207°].

**Di-methyl derivative**  $C_8H_5(OMe)_2.CO_2H$ . **Veratric acid.** [174°] (T.); [181°] (G.). S. 0.6 at 14°; .6 at 100°. Occurs in small quantity in sabadilla seeds (Merck, A. 29, 188). Formed by heating at 140° protocatechuic acid (1 pt.) with MeI (4 pts.) and KOH (1 pt.) dissolved in MeOH (Kölle, A. 159, 241). Produced also by oxidation of  $C_8H_5Me(OMe)_2$  (Tiemann, B. 8, 1138), of methyl-eugenol (Graebe, A. 158, 282), of papeverine (Goldschmidt, M. 6, 378), and of di-methyl-caffeic acid (Tiemann a. Will, B. 14, 962). Formed also by saponifying its amide, which is made by the action of ClCONH<sub>2</sub> on  $C_8H_5(OMe)_2$  in CS<sub>2</sub> in the presence of AlCl<sub>3</sub> (Gattermann, A. 244, 71). Veratric acid is a product of the action of alcoholic soda on pseudaconitine, on veratrine (Wright a. Luff, C. J. 83, 160, 553), and on hexa-methyl-quercetin (Herzig, M. 5, 83), and of fused potash on papaveraldine (Goldschmidt, M. 7, 493). Veratric acid is also got by the action of KOH on pseudo-opianic acid (W. H. Perkin, jun., C. J. 57, 1069).

**Properties.**—Slender needles (containing aq.). From hot solutions (above 50°) it separates in anhydrous crystals. V. s. sol. alcohol and ether. FeCl<sub>3</sub> gives no colour. Distillation with lime forms C<sub>8</sub>H<sub>6</sub>(OMe)<sub>2</sub>. Potash-fusion yields protocatechuic acid. HIAq at 160° forms MeI and protocatechuic acid. HClAq forms vanillic and also iso-vanillic acids.—Salts.—NaA' 2aq.—BaA', 6aq.—AgA'.—Ethers.—MeA' [60°] (c. 800°).—EtA'. [44°]. (296°).

**Di-ethyl derivative** C<sub>8</sub>H<sub>4</sub>(OEt)<sub>2</sub>.CO<sub>2</sub>H. [166°]. Formed by saponifying its ether, which is made from protocatechuic acid, alcoholic potash, and EtI (Kölle, A. 159, 240). Got also by heating hexa-ethyl-quercetin with alcoholic potash at 150° (Herzig, M. 5, 78). Needles (from alcohol).—KA' 3aq.—BaA' 3aq.—AgA'.—Ethyl ether EtA'. [57°]. Crystals.

**Methyl-ethyl derivative** C<sub>8</sub>H<sub>4</sub>(OMe)(OEt).CO<sub>2</sub>H [3:4:1]. [194°]. Formed by oxidation of ethyl-vanillin (Tiemann, B. 8, 1130), of ethyl-eugenol (Wassermann, A. 179, 379; Balbiano, G. 11, 416), and of di-ethyl-curcumin (Jackson a. Mencke, An. 4, 90). Needles, almost insol. cold water.—BaA', 4aq.; needles.

**Methyl-propyl derivative** C<sub>8</sub>H<sub>4</sub>(OMe)(OPr).CO<sub>2</sub>H [3:4:1]. Formed by oxidation of the propyl derivative of eugenol (Cahours, Bl. [2] 28, 314). Needles.

**Methyl-carboxymethyl derivative** C<sub>8</sub>H<sub>4</sub>(OMe)(O.CH<sub>2</sub>.CO<sub>2</sub>H).CO<sub>2</sub>H [3:4:1]. [256°]. Formed from C<sub>8</sub>H<sub>4</sub>(OMe)(O.CH<sub>2</sub>.CO<sub>2</sub>H).CHO by oxidation (Elkan, B. 19, 3056). Yields CuA' as a green insoluble pp.

**Methylene derivative** CH<sub>2</sub>:O<sub>2</sub>.C<sub>8</sub>H<sub>4</sub>.CO<sub>2</sub>H. **Piperonylic acid.** [228°]. Occurs in para-coto bark (Hesse a. Jobst, A. 199, 63). Prepared by oxidation of piperonal (Fittig a. Mielck, A. 152, 40). Got by heating protocatechuic acid with potash and CH<sub>2</sub>I<sub>2</sub> (Fittig a. Remsen, A. 168, 94). Piperonylic acid is also formed by the action of KMnO<sub>4</sub> on cubebin, on methystic acid (Pomeranz, M. 8, 468; 10, 790), on saffrole (Eykman, R. T. C. 4, 39; Poleck, B. 19, 1096), and on the (α)-dihydrate of piperic acid (Regel, B. 20, 415). Needles (from alcohol). May be sublimed. Nearly insol. cold water, m. sol. boiling alcohol. FeCl<sub>3</sub> gives a brown pp. in neutral solutions. Dilute HClAq at 170° forms protocatechuic acid. HNO<sub>3</sub> forms nitro-piperonylic acid [172°]. Salts.—NaA' aq.—KA' aq.—BaA', aq.—CaA', 3aq. S. 625 at 15°.—PbA', aq.—CuA', aq.—AgA'. Quinine salt C<sub>8</sub>H<sub>4</sub>N<sub>2</sub>O<sub>4</sub>.HA' aq.; needles, sol. hot water. Cinchonidine salt C<sub>8</sub>H<sub>4</sub>N<sub>2</sub>O<sub>4</sub>.HA': needles (Hesse, A. 243, 147).—Ethyl ether EtA'. Oil.—Nitrile CH<sub>2</sub>O<sub>2</sub>.C<sub>8</sub>H<sub>4</sub>.CN. [95°]. Formed from the oxim of piperonal and Ac<sub>2</sub>O (Marcus, B. 24, 8656). Needles, v. sol. alcohol. Alcoholic hydroxylamine at 60° forms the amidoxim CH<sub>2</sub>O<sub>2</sub>.C<sub>8</sub>H<sub>4</sub>.C(NH<sub>2</sub>):NOH [151°] which yields B'HCl [198°], and is converted by Ac<sub>2</sub>O into CH<sub>2</sub>O<sub>2</sub>.C<sub>8</sub>H<sub>4</sub>.C<N>CMe [110°].

**Ethylene derivative** C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>.C<sub>8</sub>H<sub>4</sub>.CO<sub>2</sub>H. [184°]. Formed by heating protocatechuic acid with ethylene bromide and KOH (Fittig, Z. [2] 7, 289; A. 168, 99). Needles (from hot water). May be sublimed. PCl<sub>5</sub> yields a product whence water reproduces ethylene-protocatechuic acid.

PCl<sub>5</sub> at 130° followed by water yields the acid C<sub>8</sub>H<sub>4</sub>Cl<sub>2</sub>O<sub>2</sub>.C<sub>8</sub>H<sub>4</sub>.CO<sub>2</sub>H [121°].—BaA', 2aq.—CaA', 2aq.; monoclinic crystals.—Ethyl ether EtA'. Oil.

**Di-methyl-ethylene ether** C<sub>8</sub>H<sub>4</sub>(O.C<sub>2</sub>H<sub>5</sub>(OMe).CO<sub>2</sub>H)<sub>2</sub>. Formed by oxidising the ethylene ether of eugenol with KMnO<sub>4</sub> (Cahours, Bl. [2] 29, 270). Amorphous.

**Reference.**—NITRO-PROTocatechuic acid.

**Homo-protocatechuic acid v. Di-ox-phenyl-acetic acid.**

**Diprotocatechuic acid** C<sub>12</sub>H<sub>11</sub>(OH)<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub>. Formed by potash-fusion from divanillin (Tiemann, B. 18, 3194). Amorphous, sl. sol. water and alcohol. Coloured bluish-green by FeCl<sub>3</sub>.

**PROTocatechuic aldehyde** C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>, i.e. C<sub>8</sub>H<sub>4</sub>(OH)<sub>2</sub>.CHO [4:3:1]. Mol. w. 138. [150°].

**Formation.**—1. From piperonal by successive treatment with PCl<sub>5</sub> and water at 100° (Fittig a. Remsen, Z. [2] 7, 100; A. 159, 148; 168, 97).—2. By heating piperonal with dilute HClAq at 200° (F. a. R.).—3. By heating a solution of pyrocatechin in dilute NaOH with chloroform (Tiemann, B. 9, 1269; 14, 2020).—4. By heating vanillin with dilute HCl at 200° (Tiemann, B. 7, 620).—5. By heating opianic acid with dilute HCl at 170° (Wegscheider, M. 3, 792).

**Properties.**—Flat needles (from water), v. sol. alcohol, ether, and hot water. FeCl<sub>3</sub> colours the aqueous solution green, changing to red on addition of Na<sub>2</sub>CO<sub>3</sub>. Oxidised by KMnO<sub>4</sub> and by potash-fusion to protocatechuic acid. Gives a mirror with ammoniacal AgNO<sub>3</sub>. Combines with NaHSO<sub>3</sub>.

**m-Methyl derivative.** C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>, i.e. C<sub>8</sub>H<sub>4</sub>(OMe)(OH).CHO. **Vanillin.** Mol. w. 152. [81°]. (285°). S. 1 at 14°; 5 at 80° (Tiemann a. Nagai, B. 10, 211). The fragrant constituent of the pods of *Vanilla aromatica* (Gobley, J. 1858, 534; Stokkebye, J. 1861, 612). Occurs also in the seeds of *Lupinus albus* (Campani a. Grimaldi, G. 17, 545), in raw beet-root sugar (Weger, D. P. J. 237, 146; Scheibler, B. 13, 335; Lippmann, B. 13, 662), in gum benzoin from Siam (Jannasch a. Rump, B. 11, 1635), and in small quantity in wood (Singer, M. 3, 409).

**Formation.**—1. Together with isovanillin, by heating guaiacol with chloroform and NaOIAq (Reimer, B. 9, 424; Tiemann, B. 14, 2023).—2. By oxidation of coniferin or coniferyl alcohol with chromic acid mixture (Tiemann, B. 7, 613).—3. By oxidation of eugenol by KMnO<sub>4</sub> (Erlenmeyer, B. 9, 273).—4. By heating calcium vanillate with calcium formate (Tiemann, B. 8, 1124).—5. By the action of chloroform and potash on vanillic acid (Tiemann, B. 9, 1280).—6. By the action of emulsin or of boiling dilute acids on glucovanillin (Haarmann a. Reimer, C. J. 46, 1343).—7. From C<sub>8</sub>H<sub>4</sub>(OMe)(NO<sub>2</sub>).CHO by reduction followed by the diazo-reaction (Ulrich, B. 18, 2573). **Properties.**—Monoclinic needles, v. sol. alcohol, ether, CHCl<sub>3</sub>, and CS<sub>2</sub>; v. sl. sol. cold, v. sol. hot, ligroin. Smells and tastes like vanilla. May be sublimed. Acid in reaction, and decomposes carbonates. FeCl<sub>3</sub> gives a blue colour. Boiling aqueous HgCl<sub>2</sub> containing KNO<sub>3</sub> gives a violet colour (Nickel, Fr. 28, 247). Reduces silver solution. Oxidised by moist air to vanillic acid C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>. **Reactions.**—1. **Bromine** forms C<sub>8</sub>H<sub>4</sub>BrO<sub>2</sub> [161°].—2. **Dilute HCl at 190°**

yields MeCl and protocatechuic aldehyde.—

3. *Potash-fusion* gives protocatechuic acid.—

4. *Sodium-amalgam* reduces it in alcoholic solution to vanillyl alcohol  $C_{10}H_{12}O_3$  as a yellowish oil, and also hydrovanillin  $C_{10}H_{12}O_2$  [c. 225°] (Tiemann, B. 8, 1123).—5. By heating with *di-methyl-aniline* and  $ZnCl_2$  it is converted into  $C_{20}H_{24}N_2O_2$  [136°] (Fischer a. Schmidt, B. 17, 1895).—6. Vanillin (1 mol.) mixed with pyrogallol (2 mols.) is converted by conc. HClAq into 'pyrogallo-vanillein'  $C_{20}H_{18}O_8$ , which forms colourless crystals, insol. water, v. sol. alcohol, giving isomeric bluish-violet crystals by the further action of HCl (Etti, M. 3, 637).—

7. Vanillin (1 pt.) boiled with *diacetoneamine acid oxalate* (1 pt.) forms the oxalate of vanillodiace-tonamine  $C_{14}H_{18}NO_8$  (v. vol. i. p. 28).—8. Heating with  $Ac_2O$  forms the acetyl derivative of vanillin, and also  $C_8H_7(OMe)(OAc).CH(OAc)_2$  [89°] crystallising in six-sided tables (Tiemann a. Nagai, B. 8, 1143).—9. Boiling aqueous  $FeCl_3$  forms di-vanillin  $C_{10}H_{12}O_4$  [304°], whence  $NaOEt$  and  $MeI$  form  $C_8H_7(OMe)_2(CHO).C_8H_7(OMe)_2(CHO)$  [138°] (Tiemann, B. 18, 3493).—10. *Chloro-acetic acid* and  $KOHAq$  form  $C_8H_7(OMe)(OCH_2CO_2H).CHO$  [188°] (Elkan, B. 19, 3056). Sals.— $*C_8H_7NaO_3$ . Needles (from alcohol), sl. sol.  $NaOH$ Aq.— $Hg(C_8H_7O_3)_2$ : crystals, sl. sol. cold water, insol. alcohol.— $Zn(C_8H_7O_3)_2$ : crystalline pp. *Estimation*.—Vanilla pods are extracted with ether, the extract shaken with a nearly saturated solution of  $NaHSO_3$ , the aqueous layer decomposed by  $H_2SO_4$ , the vanillin thence extracted by ether, and the extract evaporated (Tiemann a. Haarmann, B. 8, 1115).

*Acetyl derivative of vanillin*  $C_8H_7(OMe)(OAc).CHO$ . [77°]. Formed slowly by the action of an ethereal solution of  $Ac_2O$  on sodium-vanillin in the cold (Tiemann a. Nagai, B. 11, 646). Flat needles. Combines with bisulphites.

*Oxim of vanillin*  $C_8H_7(OMe)(OH).CH:NHOH$ . [122°] (Tiemann a. Kees, B. 18, 1661; cf. Lach, B. 16, 1786).

*Phenyl-hydrazide of vanillin*  $C_8H_7(OMe)(OH).CH:N.NHPh$ . [105°]. Plates.

*Glucoside of vanillin*  $C_8H_7(OMe)(OC_6H_4O_3).CHO$ . *Glucovanillin*. [192°].  $[a]_D = -88.63$  at 20°. Prepared by slowly adding  $CrO_3$  (8 pts.) in water (100 pts.) to coniferin (10 pts.) dissolved in water (200 pts.), and leaving the mixture to stand for 5 days (Tiemann, B. 18, 1596, 1661). Colourless needles (containing 2 aq., v. sol. water, m. sol. alcohol, insol. ether. Readily split up by dilute  $H_2SO_4$ , or by emulsin into vanillin and glucose. Does not reduce Fehling's solution in the cold. Yields  $C_8H_7(OMe)(OC_6H_4O_3).CH:N.NHPh$  [c. 195°] and a levorotatory oxim [152°], crystallising in slender yellow needles (containing aq.).

*p-Methyl-derivative*  $C_8H_7(OMe)(OH).CHO(4:3:1)$ . *Isovanillin*. [116°]. Formed by oxidising acetyl-isofurilic acid with  $KMnO_4$ , and saponifying the resulting acetyl derivative (Tiemann a. Will, B. 14, 968). Formed also by heating opianic acid (4 pts.) with water (30 pts.) and  $HClAq$  (8 pts. of S.G. 1.17) (Wegscheider, M. 3, 789). Monoclinic pyramids, sl. sol. cold water, v. sol. alcohol and ether. May be sublimed. When warm it smells somewhat like vanillin. Its alkaline solutions are yellow.

$FeCl_3$  does not colour the aqueous solution. Reduces boiling ammoniacal  $AgNO_3$ . Forms a very soluble compound with  $NaHSO_3$ .

*Di-methyl derivative*  $C_8H_7(OMe)_2.CHO$ . *Methyl-vanillin*. [43°]. (c. 233°). Formed from potassium vanillin and  $MeI$  (Tiemann, B. 8, 1135), and also by distilling opianic acid with soda-lime (Beckett a. Wright, C. J. 29, 164). Needles, v. sl. sol. hot water, v. sol. alcohol and ether. Smells like vanilla.

*Methyl-ethyl derivative*  $C_8H_7(OMe)(OEt).CHO$ . [65°]. Formed by boiling potassium-vanillin with  $EtI$  and alcohol (Tiemann, B. 8, 1129). Prisms, v. sl. sol. hot water. Smells like vanilla.

*Methylene derivative*  $C_8H_7O_3$ , i.e.  $CH_2O_2.C_8H_7.CHO$ . *Piperonal*. Mol. w. 150. [37°]. (263°). S. 2 in the cold. Formed by oxidation of piperic acid in neutral solution by  $KMnO_4$  (Fittig a. Mielek, A. 152, 35). Formed also by oxidation of the (a)-dihydrate of piperic acid by alkaline  $KMnO_4$  (Regel, B. 20, 415). Transparent prisms (from wafer), m. sol. hot water, v. sol. alcohol and ether. Smells much like coumarin. Forms a crystalline compound with  $NaHSO_3$ . Not affected by aqueous alkalis.

*Reactions*.—1. By oxidation, or by boiling with *alcoholic potash*, it is converted into piperonylic acid  $CH_2O_2.C_8H_7.CO_2H$ .—2. Reduced by water and *sodium-amalgam* to piperonyl alcohol  $C_8H_7O_3$ , hydropiperoin  $C_{10}H_{12}O_4$  [202°], and isohydropiperoin [138°].  $AcCl$  converts the hydropiperoin into  $C_{10}H_{12}ClO_4$  [198°] (Remson a. Fittig, Z. [2] 6, 97; A. 159, 129).—3. An alcoholic solution of  $KCy$  forms piperonyloin  $CH_2O_2.C_8H_7.CH(OH).CO.C_8H_7O_3.CH_2$  [120°], separating from alcohol in yellow crystals (F. M. Perkin, C. J. 59, 164).—4. Very dilute  $HClAq$  at 200° forms protocatechuic aldehyde.—5.  $PCl_5$  forms liquid  $CH_2O_2.C_8H_7.CHCl_2$  (c. 235°) and  $C_8H_7Cl_2O_3$ , whence cold water forms dichloropiperonal  $C_8H_7Cl_2O_3$  [90°].—6. Gaseous  $HCl$ , passed into a mixture of *phenyl mercaptan* and piperonal, forms  $CH_2O_2.C_8H_7.CH(SPh)_2$  [48°] (Baumann, B. 18, 886).—7. *Alcoholic ammonia*, in presence of some  $HCy$ , forms  $C_{20}H_{24}N_2O_3$ , crystallising in prisms [213°], insol. alcohol and ether. Piperonal, heated with alcoholic  $NH_3$  at 70°, forms an isomeric body [172°], crystallising in yellow needles, sol. hot alcohol, insol. water and ether (Lorenzo, B. 14, 791).—8. Aqueous  $HCy$  at 65° forms a compound whence an alcoholic solution of  $NH_3$  yields  $CH_2O_2.C_8H_7.CH(NH_2).CN$ , converted by boiling  $HClAq$  into  $C_8H_7O_3$ .—9. *Aniline* forms, on heating,  $C_8H_7NO_3$ , crystallising in colourless needles [65°] (L.).—10. *p-Phenylene-di-methyl-diamine* gives  $C_8H_7(O_2CH_2).CH:N.C_6H_4.NMe_2$  [110°] (Nuth, B. 18, 575).

*Oxim of piperonal*  $CH_2O_2.C_8H_7.CH:NHOH$ . [110°]. Needles, v. sol. alcohol (Marcus, B. 24, 3656).

*Phenyl-hydrazide of piperonal*  $CH_2O_2.C_8H_7.CH:N.NHPh$ . [100°] (M.); [103°] (Rudolph, A. 248, 103). Yellow needles.

**PROTOPINE**  $C_{20}H_{24}NO_3$ . [202°]. An alkaloid occurring in very small quantity in opium, and obtained from the mother-liquors after the separation of morphine by Gregory's process (Hesse, Z. [2] 7, 653; A. Suppl. 8, 318). Separated from cryptopine by pptn. of the solution of

the mixed hydrochlorides with conc. HOAc, the protopine salt adhering to the sides of the vessel. Crystalline powder (from alcohol), insol. water, sl. sol. hot alcohol, m. sol. chloroform. The alcoholic solution is alkaline in reaction. Sl. sol. ether, separating in spherical groups of prisms. Sl. sol. KOH aq and  $\text{NH}_4\text{Aq}$ .  $\text{FeCl}_3$  gives no colour.  $\text{HNO}_3$  forms a colourless solution, which turns yellow on warming.  $\text{H}_2\text{SO}_4$  containing ferric sulphate gives a dark-violet solution, turned dirty brownish-green at  $150^\circ$ . The salts have a bitter taste, and do not gelatinise.— $\text{B}^2\text{H}_2\text{PtCl}_2$  2aq: yellow crystalline pp.

**PRUSSIAN BLUE** v. FERRIC FERROCYANIDE, vol. ii. p. 334; and POTASSIUM-FERROUS FERRICYANIDE, vol. ii. p. 339.

**PRUSSIC ACID** v. CYANHYDRIC ACID, vol. ii. p. 300.

**PSATYRIN** v. HARTN.

**PSOROMIC ANHYDRIDE**  $\text{C}_9\text{H}_8\text{O}_6$ ? [ $264^\circ$ ]. Occurs in *Psoroma crassa*, a lichen growing in Sicily (Spica, G. 12, 431). Needles, sol. alcohol and ether, insol. benzene. Yields  $\text{C}_{20}\text{H}_{14}\text{AgO}_{10}$  as a flocculent pp.

**PSYCHOSINE**. A substance got, according to Thudichum (J. pr. [2] 25, 19), from brain.

**PTEROCARPIN**  $\text{C}_{20}\text{H}_{16}\text{O}_6$ . [ $152^\circ$ ].  $[\alpha]_D = -211^\circ$  in 4.6 p.c. chloroform solution. Obtained by mixing powdered sandal wood (*Pterocarpus santalinus*) with slaked lime, and extracting with ether. The residue is crystallised from alcohol, and the homopteroearpine dissolved in  $\text{CS}_2$ , which leaves the pterocarpine (Cazeneuve a. Hugouenq, A. Ch. [6] 17, 115). Square tables (from  $\text{CHCl}_3$ ), insol. water, m. sol. hot alcohol and hot  $\text{CS}_2$ . Insol. acids and conc. KOH aq, even on boiling. Bromine forms  $\text{C}_{20}\text{H}_{14}\text{BrO}_6$ , crystallising in yellowish needles.

**Homopteroearpin**  $\text{C}_{20}\text{H}_{16}\text{O}_6$ . [ $82^\circ$ – $86^\circ$ ].  $[\alpha]_D = -199^\circ$ . Obtained as above (C. a. H.). Long needles (from boiling alcohol), insol. water, sol. ether, v. sl. sol. cold alcohol.

**Reactions**.—1. Bromine gives  $\text{C}_{20}\text{H}_{12}\text{BrO}_6$  and  $\text{C}_{20}\text{H}_{10}\text{Br}_2\text{O}_6$  [ $270^\circ$ ].—2. On distillation it is largely split up into phenols resembling creosote, and a small quantity of pyrocatechin.—3. Distillation over zinc-dust gives benzene, toluene, ethylene, and  $\text{CO}$ .—4.  $\text{HCl}$  gives  $\text{MeCl}$  and a resin.—5.  $\text{HI}$  gives  $\text{MeI}$ .—6. Potash-fusion gives phloroglucin.—7. Fuming  $\text{HNO}_3$  gives oxalic acid and tri-nitro-orein [ $162^\circ$ ]. Not acted upon by sodium-amalgam, phenyl-hydrazine, and  $\text{Ac}_2\text{O}$ .

**PTOMAINES**. The name 'ptomaines' was first applied to poisonous organic bases obtained from dead bodies (*πρωμα*, a corpse), but is now usually given to poisonous organic bases formed in the putrefaction of any kind of animal matter. In extracting ptomaines no reagents that would decompose proteids may be used. The bases may be extracted by alcohol, and purified by ppn. with phosphomolybdic acid. In presence of a little  $\text{HCl}$  the ptomaines are fairly stable, and the solution can then be evaporated and the hydrochlorides extracted from the syrupy residue by absolute alcohol. By this method neuridine hydrochloride can readily be obtained. By the putrefaction of proteids Brieger (Two monographs: *Ueber Ptomaine*, Berlin, 1885; cf. Gautier, Bl. [2] 48, 10) obtained tri-methyl-vinyl-ammonium hydroxide (neurine)  $\text{C}_8\text{H}_{11}\text{NO}$  or  $\text{C}_8\text{H}_7\text{NMe}_3\text{OH}$ , muscarine  $\text{C}_8\text{H}_{11}\text{NO}$ , or

$\text{CH}(\text{OH})_2\text{CH}_2\text{NMe}_3\text{OH}$  (vol. iii. p. 444), a base isomeric with ethylene-diamine, neuridine  $\text{C}_8\text{H}_{11}\text{N}$ , gadinine  $\text{C}_8\text{H}_{11}\text{NO}$ , triethylamine, dimethylamine, and trimethylamine. Garcia (H. 17, 543) got hexamethylene-diamine  $\text{C}_6\text{H}_{12}\text{N}_2$ . Herring-pickle contains choline,  $\text{NMe}_3$ , and  $\text{NH}_4\text{Me}$ . By the putrefaction of the herring  $\text{NMe}_3$ ,  $\text{NH}_4\text{Me}$ , cadaverine  $\text{C}_8\text{H}_{11}\text{N}$ , putrescine  $\text{C}_8\text{H}_{11}\text{N}$ , and gadinine  $\text{C}_8\text{H}_{11}\text{NO}$ , are formed (Bocklisch, B. 18, 1922). Gautier and Etard (C. R. 94, 1600) from putrid mackerel and putrid horse-flesh obtained a collidine dihydride  $\text{C}_8\text{H}_{11}\text{N}$ , parvoline  $\text{C}_8\text{H}_{11}\text{N}$ , and a base  $\text{C}_8\text{H}_{11}\text{N}$ . In the putrefaction of proteids poisonous bases are formed in the first five or six days, and are destroyed by further progress of putrefaction. The highly poisonous methyl-guanidine is formed by the action of putrefactive bacteria on beef-broth at  $38^\circ$  (Bocklisch, B. 20, 1441). From human corpses Brieger obtained tri-methyl-oxyethyl-ammonium hydroxide  $\text{C}_3\text{H}_7\text{NO}_2$  or  $\text{CH}_3(\text{OH})\text{CH}_2\text{NMe}_3\text{OH}$  (choline or neurine, vol. iii. p. 498), neuridine  $\text{C}_8\text{H}_{11}\text{N}$ , cadaverine  $\text{C}_8\text{H}_{11}\text{N}$ , putrescine  $\text{C}_8\text{H}_{11}\text{N}$ , saprine  $\text{C}_8\text{H}_{11}\text{N}$ , trimethylamine, methyl-guanidine, tetanine  $\text{C}_{12}\text{H}_{19}\text{N}_3\text{O}$ , mydine  $\text{C}_8\text{H}_{11}\text{NO}$ , mydatoxin  $\text{C}_8\text{H}_{11}\text{NO}$ , and mydaleine (Brieger, loc. cit.; cf. Selmi, Rend. Accad. Sci. Bologna, 1872; Schwanert, B. 7, 1332; Guareschi a. Mossio, J. pr. [2] 27, 428; 28, 504; G. 13, 493; Beckurts, Ar. Ph. [3] 14, 1041). Ptomaines are often produced in animal bodies which, after brief exposure, have been excluded from the air; e.g. corpses, sausages, and tinned meat. A crystalline ptomaine can be obtained from the body after arsenical poisoning (Husemann, Ar. Ph. [3] 16, 169; 19, 415). The alcoholic solution of hydrochlorides of ptomaines may be ppd. by an alcoholic solution of  $\text{HgCl}_2$ ; after twenty-four hours' standing, the pp. is boiled with a large quantity of hot water, which leaves the compounds of peptones and albuminates undissolved. The hot filtrate deposits the mercury double salt of choline (neurine) while the mother-liquor contains the remaining bases. Picric acid added to an aqueous solution of the hydrochlorides ppt. neuridine picrate, while the mother-liquor deposits, on evaporation, broad needles of choline picrate  $\text{C}_8\text{H}_{11}\text{NOC}_6\text{H}_3(\text{NO}_2)_3\text{OH}$ . Cadaverine and putrescine can be separated by means of their aurochlorides. Saprine is isolated by means of its platinumchloride. To distinguish a ptomaine from a vegetable alkaloid, Brouardel a. Boutmy (C. R. 92, 1056; cf. Tanret, C. R. 92, 1163) add a few drops of the solution of the sulphate of the alkaloid to potassium ferricyanide mixed with  $\text{FeCl}_3$ ; a dark-blue pp. is formed if a ptomaine be present, while the vegetable alkaloids (except morphine, veratrine, eserine, aconitine; and ergotinine) have no action. The test is, of course, given by many other reducing agents. This ptomaine reaction is given (slowly) by a poisonous liquid alkaloid extracted by Stas's method from the intestines of persons who died of cholera (Villiers, C. R. 100, 91). Pouchet (C. R. 97, 1560; cf. Gautier, B. C. 1882, 710; Béchamp, C. R. 94, 973) obtained from urine and faeces some alkaloids closely resembling the ptomaines got by putrefaction of proteids out of contact of air. He separated them by decomposing their tannates with  $\text{Pb}(\text{OH})_2$  in presence of alcohol, the lead being finally re-

moved by  $H_2S$ , and the liquid dialysed.  $C_8H_{11}NO_2$  is liquid and dialyses with difficulty; it exhibits the alkaloidal reactions, is resinified by  $HCl$ , and reduces platino chloride. The base  $C_8H_{11}N_2O_2$  or  $C_8H_{11}N_2O$  is crystalline, and passes through the membrane; it is insol. ether, nearly insol. alcohol, is feebly alkaline and yields crystalline salts. From the dialysate the platinochlorides of two crystalline unstable bases  $C_8H_{11}N_2O$ , and  $C_8H_{11}N_2O_2$  can be got. Urine which had a tendency to deposit cystin and the faeces of the same patient contained cadaverine and putrescine (Baumann, *H.* 13, 562; cf. Dupré a. Bence-Jones, *Pr.* 15, 73; Stadthagen a. Brieger, *Ar. pathol. Anat.* 115, pt. 3). These diamines appear to be absent from normal urine, but present in cholera.

**Cadaverine** is PENTAMETHYLENE-DIAMINE, vol. iii. p. 805.

**Putrescine** is TETRAMETHYLENE-DIAMINE.

**Mydaleine** is extremely poisonous, while **gadinine** is not poisonous.

**Mydine**  $C_8H_{11}NO$ . Occurs in putrid corpses (Brieger, *Ptomaine*, iii. 25). Has an ammoniacal odour and reduces gold chloride. Not poisonous. —  $B'O_2H_2N_2O_2$ . [195°]. Broad prisms.

**Base**  $C_8H_{11}NO_2$ . Occurs in decaying horse-flesh, four months old (Brieger). Acid in reaction. Poisonous. Does not form a picrate. —  $B'HAuCl_4$ . [176°]. Needles or plates.

**Typhotoxin**  $C_8H_{11}NO_2$ . Formed by the action of the typhus bacillus on muscle (Brieger, *Ptomaine*, iii. 86). Poisonous base. —  $B'HAuCl_4$ . [176°]. Prisms.

**Mydatoxin**  $C_8H_{11}NO_2$ . Occurs in decaying horse-flesh and corpses (B.). Poisonous. Strongly alkaline. —  $B'H_2PtCl_6$ . [193°]. V. e. sol. water.

**Tetanine**  $C_{12}H_{23}N_2O_2$ . Occurs in decaying corpses (Brieger, *B.* 19, 3120), and is formed by the action of the tetanus bacillus on beef. Very poisonous base. —  $B'H_2PtCl_6$ . Plates.

**Base**  $C_8H_{11}N$ . (c. 100°). Accompanies tetanine, and also produces convulsions (B.). Volatile liquid. Its hydrochloride is crystalline [205°]. —  $B'HAuCl_4$ . [130°]. —  $B'H_2PtCl_6$ . Plates, decomposed at 240°.

**Base**  $C_8H_{11}N$ . Oily ptomaine, smelling like hawthorn (Deleznier, *Bl.* [3] 1, 178). In presence of air it acts chemically and physiologically like veratrine. Insol. water, sol. alcohol and ether. Its salts are deliquescent.

**Base**  $C_8H_{11}NO_2$ . [156°]. Occurs in putrid flesh and putrid fibrin (E. a. H. Salkowski, *B.* 16, 1192). Crystalline powder, v. e. sol. water. Not poisonous. —  $B'HCl$ : crystals, v. e. sol. water. —  $B'HAuCl_4$ : yellow crystals.

**Base**  $C_{11}H_{21}NO_2$ . *Erysipeline*. Occurs in urine in erysipelas (Griffiths, *C. R.* 115, 667). Prisms, sol. water. Very poisonous.

**Base**  $C_{12}H_{23}NO_2$ . Occurs in urine in puerperal fever (G.). Crystalline and poisonous.

**Base**  $C_{11}H_{21}N$ . A product of the decomposition of albumen by *Bacterium allii*, which is found in decaying onions (A. B. Griffiths, *C. R.* 110, 416). Minute deliquescent needles (from water), smelling like hawthorn. —  $B'H_2PtCl_6$ : crystalline, sol. hot water.

**Base**  $C_{11}H_{21}NO_2$ . Occurs in urine of victims to glanders (A. B. Griffiths, *C. R.* 114, 1882). White crystals. Poisonous. Forms crystalline salts.

**Base**  $C_{20}H_{39}N_2O_2$ . Occurs in urine in cases of pneumonia (G.). Minute needles, forming an alkaline aqueous solution [ $\alpha_D$ ] = 23.5°.

**Base**  $C_8H_{11}N$ . (202°). S.G. 2-9865. Extracted, together with a base  $C_{10}H_{19}N$  from putrid cuttlefish (De Coninck, *C. R.* 106, 858, 1604; 108, 58, 809; 110, 1339; 112, 584). Mobile, strongly-smelling liquid, v. sol. water, alcohol, and ether. Turns brown in air. Appears to be a propylpyridine, as it yields nicotinic acid on oxidation by dilute  $KMnO_4$  at 90°. —  $B'HCl$ : deliquescent radiating mass. —  $B'H_2PtCl_6$ . Converted by hot water into  $B'H_2PtCl_6$ , a nearly insoluble brown powder. —  $B'HAuCl_4$ . —  $B'HBr$ . —  $B'H_2HgCl_4$ . —  $B'H_2HgCl_4$ . —  $B'Mel$ . Needles, v. e. sol. alcohol.

**Base**  $C_{10}H_{19}N$ . (230°). Formed as above. Liquid, smelling like furze. Resinified by air. —  $B'HBr$ . White deliquescent needles. —  $B'HCl$ . —  $B'H_2PtCl_6$ . —  $B'H_2PtCl_6$ . [206°]. —  $B'HAuCl_4$ : yellow pp., decomposed by hot water.

**Base**  $C_{10}H_{19}N$ . (200°). Extracted by Stas's method from fibrin that has putrefied for two months (Guareschi a. Mosso, *J. pr.* [2] 27, 428; *J. Th.* 1887, 487). Yields the alkaloidal reactions. Smells like pyridine. Acts physiologically like curare. —  $B'H_2PtCl_6$ : rose-red crystals.

**Base**  $C_{11}H_{23}NO_2$ . [250°]. Formed in the putrefaction of fibrin, from which it can be extracted, together with the liquid alkaloid  $C_{10}H_{19}N$ , by chloroform and ether (Guareschi, *G.* 17, 509). Tables (from alcohol), sol. water and alcohol, v. sl. sol. chloroform. Its aqueous solution is neutral. Griffiths (*Bl.* [2] 7, 250; *C. R.* 113, 656) got, from urine of patients suffering from erysipelas, a crystalline ptomaine 'erysipeline'  $C_{11}H_{23}NO_2$ , sol. water, and very poisonous. It gives the alkaloidal reactions.

The term *leucomaine* (λευκόμα, white of egg) is applied by Gautier (*Sur les Alcaloïdes des Tissus Animaux*, Paris, 1886) to alkaloids occurring in the tissues of living animals. From fresh beef and Liebig's extract of beef he obtained xanthocreatinine  $C_8H_{11}N_2O$ , crysocreatine  $C_8H_{11}N_2O$ , amphicreatinine  $C_8H_{11}N_2O$ , pseudoxanthine  $C_8H_{11}N_2O$ , and two feeble bases  $C_{11}H_{23}NO_2$  and  $C_{12}H_{25}NO_2$ , both crystallising in tables.

**Xanthocreatinine**  $C_8H_{11}N_2O$ . Thin sulphur-yellow tables, v. e. sol. water, sol. boiling alcohol. Gives an odour of roast meat when heated. Resembles creatinine.

**Chrysocreatine**  $C_8H_{11}N_2O$ . Orange crystals, with feebly alkaline reaction. Sl. sol. water. Resembles creatinine.

**Amphicreatinine**  $C_8H_{11}N_2O$ . Yellow prisms, sl. sol. water. A weak base, resembling creatinine.

**Pseudoxanthine**  $C_8H_{11}N_2O$ . Yellow crystalline powder, sl. sol. cold water, sol.  $HClAq$  and  $NaOHAq$ . Reacts with  $HNO_3$  and  $KOH$  like xanthine.

**Carnine** v. vol. i. p. 710.

**PTYALIN** v. vol. ii. p. 545.

**PTYCHOTIS OIL**. The essential oil got from the seeds of *Ptychotis ajowan*, an umbelliferous plant growing in Central India, contains thymol and a terpene  $C_{10}H_{18}$ . (172°) S.G. 12-854 (Stenhouse, *C. J.* 9, 234; cf. Haines, *C. J.* 8, 289).

**PULEGIUM OIL**. The essential oil of *Pulegium micranthum*, growing on the Steppes of Southern Russia, contains oily  $C_{10}H_{18}O$  (237°)

**S.G. 11-932** (Butlerow, J. 1854, 594). It yields acetic and valeric acid when fused with potash. The oil of *Mentha pulegium* is described under **PEMNTROYAL**.

**PULVIC ACID**  $C_6H_4O_3$ , i.e.

$CO_2H.CPh:C \begin{smallmatrix} \diagup O(H)CPh \\ \diagdown CO \end{smallmatrix}$ . [215°]. Prepared

by the action of cold  $NaOH$ aq on a solution of the anhydride in acetone, and also by boiling vulpic acid with milk of lime (Spiegel, B. 13, 1630, 2219; 14, 1686; 15, 1550; A. 219, 1). Orange crystals or yellow plates (containing  $EtOH$ ), sol. alcohol and ether, sl. sol. water. Decomposed by baryta-water into phenyl-acetic and oxalic acids. Alkaline  $KMnO_4$  oxidises it to phenyl-glyoxylic and oxalic acids. On reduction by zinc-dust and  $NH_3$ aq it gives a mixture of carboxy-cornicularic acid ( $C_{11}H_{11}O_5$ ), cornicularic acid ( $C_{11}H_{11}O_4$ ), and the two dihydrides of cornicularic acid ( $C_{10}H_{11}O_4$ ).

**Salts.**— $BaA''$  aq: golden plates.— $AgHA''$ : small prisms.— $Ag_2A''$  aq: long needles.

**Methyl ether** v. **VULPIC ACID**.

**Ethyl ether**  $EtA'$ . [128°]. Prepared by dissolving the anhydride in alcoholic potash.

**Methyl derivative of the methyl ether**  $C_{11}H_{11}Me_2O_4$ . [139°]. Colourless needles.

**Anhydride**  $C_{10}H_{11}O_4$ , i.e.

$CO.O.C:CPh > CO$ . [221°]. Formed, together

with  $MeOH$ , by heating vulpic acid at 200°. Colourless needles, sl. sol. alcohol, insol. water. Converted by ammonia into  $C_{10}H_{11}(NH_2)O_4$  [220°] crystallising in yellow prisms.

**PUNICIN**. The purple of the ancients. Extracted from *Purpura capillus* and other shellfish which yield a colourless secretion which becomes purple on exposure to sunlight (Schunck, C. J. 35, 689; 37, 613). Obtained in Central America from *Purpura patula*. Yarn dyed by the Indians is warmed with  $HCl$  and then with ether. The colouring matter is then extracted with aniline, which on cooling deposits punicin as a crystalline powder, insol. boiling alcohol and ether, sl. sol. benzene and  $HOAc$ . Its solution in aniline shows an absorption band between C and D, with a sharp edge towards C. The band resembles that of indigo, but it disappears sooner on standing. In phenol it forms a sky-blue solution. Its solution in conc.  $H_2SO_4$  shows an absorption band between D and E; this disappears on standing, the liquid becoming bright green. Water precipitates the purple from this solution, so that a sulphonic acid is not formed. Punicin begins to sublime at 190°. It is hardly attacked by  $HNO_3$  (S.G. 1-2) or by aqueous  $CrO_3$ . With bromine it reacts, forming a body which crystallises from alcohol in yellow needles. Punicin dissolves in aqueous  $SnCl_2$ , but is deposited again on exposing the solution to air.

**PURPLE OF CASSIUS**. A purple-coloured solid, obtained by adding  $SnCl_2$ aq to  $AuCl_3$ aq in presence of a reducing agent; v. **TIN**, oxides or, in this volume.

**PURPURIC ACID**  $C_6H_3N_3O_6$ . Not known in the free state.

**Salts.**— $(NH_4)HA''$  aq. Murexide. Formed by heating ammonium dialurate; by oxidising uranil with  $HgO$ ; and by adding ammonia or ammonium carbonate to a mixture of

alloxan and alloxantin (Prout, A. Ch. 11, 48; Kodweiss, P. 19, 12; Liebig a. Wohler, A. 26, 319; Fritzsche, J. pr. 16, 380; 17, 47; Beilstein, A. 107, 176; Laurent, C. R. 35, 629; Gregory, A. 33, 334). Garnet-red four-sided prisms with golden-green lustre; when dried in *vacuo* it forms a brown powder. M. sol. hot water, forming a purple solution, insol. alcohol and ether. Decomposed by acids with formation of uranil and alloxan. The absorption spectrum has been studied by Hartley (C. J. 51, 199).—**KHA''**. Crystals resembling murexide, forming in cold  $KOHAq$  a blue solution decolourised by heat.— $NaHA''$ .— $BaA''$  3aq; dark-green powder.— $AgHA''$  1½aq; brownish-red powder.— $Ag_2A''$ .

**Isopurpuric acid** v. **TRI-NITRO-PHENOL**, Reaction 5.

**Metapurpuric acid** v. (a)-**DI-NITRO-PHENOL**, Reaction 2.

**PURPUREO-CHROMIUM SALTS** v. **CHROM-AMMONIUM SALTS**, vol. ii. 159-60.

**PURPUREO-COBALT SALTS** v. **COBALT-AMINES**, vol. ii. pp. 227-8.

**PURPUREO-RHODIUM SALTS** v. **RHODIUM-AMMONIUM COMPOUNDS**.

**PURPURIN** v. **TRI-OXY-ANTHRAQUINONE**.

**PURPUREOGALLIN**  $C_{20}H_{16}O_8$ . *Pyrogallol-quinone*. [256°]. Formed by the slow oxidation of pyrogallol (Struve, A. 163, 162; Girard, Z. 1870, 86; Wichellhaus, B. 5, 848; De Clermont a. Chautard, C. R. 94, 1362; 102, 1072; Nietzki a. Steinmann, B. 20, 1277; Loew, J. pr. [2] 15, 322). Formed also by the action of aqueous  $KNO_3$  on gallic acid (Hooker, B. 20, 3259). Obtained also from pyrogallol and quinone (Wichellhaus, B. 5, 847; Nietzki, B. 18, 1278). Prepared by adding a solution of  $K_2FeCy_6$  (87 g.) in water (330 c.c.) to pyrogallol (20 g.) dissolved in cold water (330 c.c.), and filtering after half an hour; the yield is small (3 g.). Dark-brown needles (from alcohol). May be sublimed. V. sl. sol. water, sl. sol. alcohol, m. sol. ether. Reduces  $AgNO_3$  and Fehling's solutions.  $H_2SO_4$  forms a crimson solution changed to violet by  $HNO_3$ . Ammonia forms a blue solution, changing through green to dark yellow. Yields naphthalene on distillation with zinc-dust. According to De Clermont and Chautard purpureogallin yields  $Na_2A''$  crystallising in deliquescent needles,  $Ba_2A''$  as crystalline plates,  $C_{20}H_{16}Br_2O_8$  as red needles [204°] and  $C_{20}H_{16}Ac_2O_8$  [186°]. By heating with  $H_2SO_4$  these chemists obtained  $SO$  and  $C_{20}H_{16}O_{10}$ , which crystallised in brown needles forming a blue solution in  $KOHAq$ .

**PURPUREOXANTHIN** v. **m-DI-OXY-ANTHRAQUINONE**.

**PURREIC ACID** v. **EUXANTHIC ACID**.

**PUTREFACTION** v. **FERMENTATION**.

**PUTREFACTIVE ALKALOIDS** v. **PTOMAINES**.

**PUTRESCINE** v. **TETRA-METHYLENE-DIAMINE**.

**PYKNOMETER**. This name is sometimes given to various forms of the specific gravity bottle, for determining the relative densities of liquids (cf. **DENSITIES**, RELATIVE, vol. ii. p. 373).

**PYRANIL-PYROIC ACID**  $C_{11}H_8NO(CO_2H)$ . [165°]. Formed by heating phenyl-amido-pyrotartaric acid  $CO_2H.CH_2.CMe(NHPh).CO_2H$  a little above its melting-point for some time (Reissert a. Tiemann, B. 19, 622; 21, 1942, 3257; 22, 2281; 24, 314). Crystalline powder, sl. sol.

water, alcohol, and ether. Converted by heating strongly into the phenyl-imides of citraconic acid and of phenyl-amido-pyrotartaric acid. According to Anschütz (B. 21, 3252; 22, 731; 23, 895, 2979; A. 246, 115; 248, 269), pyranil-pyrollic acid is the mono-anilide of mesaconic acid.

**PYRAZINE.** This name is used to denote the ring  $\text{N} \begin{smallmatrix} \text{CH:CH} \\ \text{CH:CH} \end{smallmatrix} \text{N}$ .

**Pyrazine hexahydride**  $\text{C}_4\text{H}_{10}\text{N}_2$ , i.e.  $\text{NH} \begin{smallmatrix} \text{CH}_2\text{CH}_2 \\ \text{CH}_2\text{CH}_2 \end{smallmatrix} \text{NH}$ . *Piperazine*. *Di-ethylene-diamine*. [104°–107°]. (137° uncor.). Formed from ammonia and ethylene bromide (Cloez, *Instit.* 1843, 213) or ethylene chloride (Natanson, A. 92, 48; 98, 291; Hofmann, *Pr.* 10, 224; 11, 278; B. 23, 3297). Formed also by boiling  $\text{NO.C}_2\text{H}_4\text{N} \begin{smallmatrix} \text{CH}_2\text{CH}_2 \\ \text{CH}_2\text{CH}_2 \end{smallmatrix} \text{N.C}_2\text{H}_4\text{NO}$  with alcoholic potash (Bischler, B. 24, 717). According to Majert a. Schmidt (B. 24, 241), it is not identical with spermine. Glittering tables (from water). May be sublimed. Strongly alkaline and absorbs  $\text{CO}_2$  from the air.

**Reactions.**—1. Aqueous  $\text{NaOCl}$ , saturated with  $\text{Cl}$ , forms  $\text{ClN} \begin{smallmatrix} \text{CH}_2\text{CH}_2 \\ \text{CH}_2\text{CH}_2 \end{smallmatrix} \text{NCl}$  [71°], crystallising in prisms, v. sl. sol. water, v. sol. alcohol (Schmidt a. Wichmann, B. 24, 3243). This body explodes at 80°–85°. Bromine water forms the corresponding di-bromo-piperazine, which is very unstable.—2. *Diazobenzene chloride* and  $\text{NaOHAq}$  form  $\text{Ph.N}_2\text{N.C}_2\text{H}_4\text{N.N}_2\text{Ph}$  [129°] (S. a. W.).—3. *Benzoin aldehyde* yields the compound  $(\text{N.C}_2\text{H}_4\text{N})\text{CHPh}$  [247°] (Schmidt a. Wichmann, B. 24, 3212).—4. *Quinone* forms an amorphous violet-brown body, almost insol. alcohol.—5. *Hydroquinone* in alcoholic solution forms  $\text{C}_6\text{H}_2\text{N}_2\text{C}_6\text{H}_2\text{O}_2$ , crystallising in needles [195°].—6. *Phenol* forms  $\text{C}_6\text{H}_3\text{N}_2\text{PhOH}$  [101°], crystallising from spirit in prisms, v. sol. water.—7. *Oxalic ether* at 110° reacts forming the ether  $\text{CO}_2\text{Et.CO.N:C}_2\text{H}_4\text{N.CO.CO}_2\text{Et}$  [124°] crystallising in broad needles (S. a. W.).—8. *p-Chloronitro-benzene* at 150° gives the compound  $\text{NO}_2\text{C}_6\text{H}_4\text{N:C}_2\text{H}_4\text{N.C}_6\text{H}_4\text{NO}_2$  [248°] (Schmidt a. Wichmann, B. 24, 3240).

**Salts.**— $\text{B}''\text{H}_2\text{Cl}$ , aq.: needles, v. sol. water.— $\text{B}''\text{H}_2\text{PtCl}_6$ — $\text{B}''\text{H}_2\text{AuCl}_4$ — $\text{B}''\text{H}_2\text{HgCl}_4$ : stellate groups of needles (Sieber, B. 23, 326).— $\text{B}''\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$ : yellow needles.—**Carbonate**: [162°–165°].—**Urate**:  $\text{B}''\text{C}_6\text{H}_5\text{N}_2\text{O}_2$ . The phosphate and the bismutho-iodide are crystalline.

**Di-acetyl derivative**  $\text{C}_8\text{H}_8\text{N}_2\text{Ac}_2$ . [138°–5°]. (above 310°). Formed from piperazine and  $\text{Ac}_2\text{O}$ . Needles, v. e. sol. water and alcohol.

**Nitrosamine**  $\text{NO.N:C}_2\text{H}_4\text{N.NO}$ . [158°] (Ladenburg, B. 24, 2640; Schmidt, B. 24, 3245; G. P. 12, 59222). Reduced by zinc-dust and  $\text{HOAc}$  to  $\text{NH}_2\text{N:C}_2\text{H}_4\text{N.NH}_2$ , which crystallises in needles [0. 100°] (228°), and yields  $\text{B}''\text{HCl}$ ,  $\text{B}''\text{C}_6\text{H}_5\text{N}_2\text{O}_2$ , an amorphous di-benzoyl derivative, and reacts with benzoic aldehyde, forming  $\text{CHPh.N:N:C}_2\text{H}_4\text{N.N:CHPh}$  [205°], which crystallises in pearly plates.

**PYRAZOLE**  $\text{C}_4\text{H}_4\text{N}_2$ , i.e.  $\text{CH:N} \begin{smallmatrix} \text{CH:CH} \\ \text{CH:CH} \end{smallmatrix} \text{NH}$ . [70°]. (187°). Formed by heating the tri-carboxylic acid produced by saponification of the product

of direct addition of diazoacetic ether and acetylene dicarboxylic ether (Buchner, B. 22, 2165). Formed also by heating hydrazine hydrate (10.8 g.) with epichlorhydrin (10 g.) and  $\text{ZnCl}_2$  (11 g.) (Balbiano, B. 23, 1193). Needles, v. sol. cold water, forming a neutral solution, sol. alcohol and ether. Gives a white pp. with  $\text{HgCl}_2$ , and also with ammoniacal  $\text{AgNO}_3$ .

**Salts.**— $\text{B}''\text{HCl}$ . Hygroscopic prisms.— $\text{B}''\text{H}_2\text{PtCl}_6$ , 2aq. At 210° it is split up into  $\text{HCl}$  and  $(\text{C}_2\text{H}_5\text{N}_2)_2\text{PtCl}_2$ , a light-yellow powder.— $\text{AgC}_2\text{H}_3\text{N}_2$ , sl. sol. water.— $\text{B}''\text{C}_6\text{H}_5\text{N}_2\text{O}_2$ . [160°].

**PYRAZOLE BLUE**  $\text{C}_{20}\text{H}_{16}\text{N}_4\text{O}_2$ , i.e.  $\text{N.NPh.CO.CO.NPh.N}$

$\text{CMo}=\text{C}=\text{C}=\text{CMo}$ . Formed by oxidation of di-oxy-di-phenyl-di-methyl-dipyrazyl (Knorr, A. 238, 172; B. 25, 765). Sol. chloroform, conc.  $\text{H}_2\text{SO}_4$  and  $\text{HIOAc}$ . Its spectrum resembles that of bodies of the indigo group. Decomposes about 230°. Its sulphonic acid, got by the action of  $\text{Br}$  on di-oxy-di-phenyl-di-methyl-dipyrazyl disulphonic acid, is destroyed by excess of bromine (Möllenhoff, B. 25, 1919).

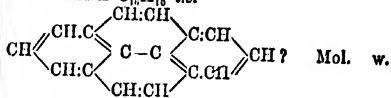

**o-PYRAZYL-BENZOIC ACID**  $\text{C}_{10}\text{H}_6\text{N}_2\text{O}_2$ , i.e.  $\text{CH:N} \begin{smallmatrix} \text{CH:CH} \\ \text{CH:CH} \end{smallmatrix} \text{N.C}_6\text{H}_4\text{CO}_2\text{H}$ . [130° cor.]. Formed by oxidising o-tolyl-pyrazole with  $\text{KMnO}_4$  (Balbiano, G. 19, 123). Yellow needles (from dilute alcohol).— $\text{BaA}''$ .

*Ethyl ether*  $\text{EtA}'$ . (309° i.v.).

*p-Pyrazyl-benzoic acid*. [265°]. Got in like manner from p-tolyl-pyrazole.— $\text{NaA}'$ .— $\text{BaA}''$ .

*Ethyl ether*  $\text{EtA}'$ . [62°]. Tables.

**PYRENE**  $\text{C}_{16}\text{H}_{10}$ , i.e.

202. [149°]. (above 360°). S. (alcohol) 1:87 at 16°; 3:08 at 78°; S. (toluene) 16:6 at 18° (Ilechi, B. 12, 1978). Occurs in coal tar (Graebe, A. 158, 285). Monoclinic tables (Fittig a. Hintz, B. 10, 2143), v. e. sol.  $\text{CS}_2$  and ether. Yields pyrene-quinone and pyrenic acid on oxidation.  $\text{SnCl}_4$  at 360° forms  $\text{C}_{14}\text{Cl}_4$ ,  $\text{C}_{14}\text{Cl}_{10}$  [above 800°],  $\text{C}_{14}\text{Cl}_{16}$  [above 300°], and other bodies (Merz a. Weith, B. 16, 2880). Bromine forms crystalline  $\text{C}_{16}\text{H}_8\text{Br}_2$  and  $\text{C}_{16}\text{H}_8\text{Br}_4$  (Graebe).

**Picric acid compound**  $\text{C}_{16}\text{H}_8\text{O}_6\text{H}_3\text{N}_3\text{O}_9$ . [222°]. Red needles (from alcohol), v. sl. sol. cold alcohol, m. sol. ether, v. sol. benzene.

**Hexahydride**  $\text{C}_{16}\text{H}_{16}$ . [127°]. Formed by heating pyrene with  $\text{HIAq}$  and  $\text{P}$  at 200°. Needles, v. e. sol. ether and boiling alcohol. Its alcoholic solution is not ppd. by picric acid.

**Chloropyrenes.** The following chloro-pyrenes are formed by passing  $\text{Cl}$  into a solution of pyrene in chloroform. They are separated by fractional crystallisation from alcohol, chloroform, and xylene (Goldschmidt a. Wegscheider, M. 4, 237).

$\text{C}_{16}\text{H}_8\text{Cl}_2$ . [119°]. Golden needles, forming in  $\text{H}_2\text{SO}_4$  a solution with violet fluorescence. Yields  $\text{C}_{16}\text{H}_8\text{Cl}_4\text{C}_6\text{H}_5\text{N}_2\text{O}_2$ . [177°].

$\text{C}_{16}\text{H}_8\text{Cl}_4$ . Two di-chloro-pyrenes [156°] and [196°].

$\text{C}_{16}\text{H}_8\text{Cl}_6$ . [257°]. White needles.

$\text{C}_{16}\text{H}_8\text{Cl}_8$ . [above 330°]. Needles.

**Nitropyrene**  $\text{C}_{16}\text{H}_8\text{NO}_2$ . [150°]. Formed by slowly adding  $\text{H}_2\text{SO}_4$  to aqueous  $\text{KNO}_3$ , under an

etheral solution of pyrene (Goldschmiedt, *M.* 2, 580). Yellow needles (from alcohol), sl. sol. cold alcohol.

**Di-nitro-pyrene**  $C_{16}H_8(NO_2)_2$ . Formed from pyrene and  $MNO_3$  (S.G. 1.45). Yellow needles (from HOAc). Reduced by tin and HCl to di-amido-pyrene (Jahoda, *M.* 8, 449).

**Tetra-nitro-pyrene**  $C_{16}H_8(NO_2)_4$ . [above 800°]. Yellow needles (from HOAc), nearly insol. alcohol.

**Amido-pyrene**  $C_{16}H_8NH_2$ . [116°]. Got by reducing nitropyrene. Needles, sl. sol. water. —  $B'H_2SO_4$  (dried at 100°). —  $B'HCl$ . Its solution dyes fir-wood red.

**PYRENE CARBOXYLIC ACID**  $C_{16}H_8CO_2H$ . [287°]. Formed by fusing its nitrile with potash (Goldschmiedt a. Wegscheider, *M.* 4, 256). Needles, sl. sol. water. Resolved by heat into pyrene and  $CO_2$ . —  $CaA'$ , aq. —  $BaA'_2$  2½aq.

**Nitrile**  $C_{16}H_7CN$ . [150°]. Formed, together with the nitrile of the dicarboxylic acid, by heating potassium pyrene disulphonate with  $K_2CO_3$  or  $K_2FeCy_4$ . Needles (from alcohol). The solutions of this body show green fluorescence. —  $(C_{16}H_7N)_3CH_3N_3O_6$ . [134°]. Red needles, decomposed by alcohol.

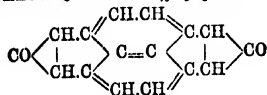

**Pyrene dicarboxylic acid**  $C_{16}H_8(CO_2H)_2$ . [above 800°].

**Nitrile** [above 300°].  $C_{16}H_7(CN)_2$ . Formed as above. Yellow powder. Its solutions show green fluorescence.

#### PYRENE-KETONE $C_{16}H_8O$ i.e.

[1:1]  $C_{16}H_8 \begin{smallmatrix} CH \\ < \\ CH \end{smallmatrix} > CO$ . [142°]. Formed by distilling pyrenic acid with slaked lime (Bamberger a. Philip, *B.* 19, 1996, 3040; 20, 371; *A.* 240, 178). Golden tables (from dilute alcohol), volatile with steam. Reduced by zinc and HCl to  $C_{16}H_8(CH_2OH)_2$ . Oxidised by  $KMnO_4$  to naphthalene (1,1')-dicarboxylic acid.

#### PYRENE-QUINONE $C_{16}H_8O_2$ i.e.

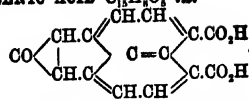

(Bamberger a. Philip, *B.* 20, 369; *A.* 240, 166). [o. 282°]. Formed by oxidation of pyrene by chromic acid mixture (Graebe, *A.* 158, 295; Goldschmiedt, *M.* 4, 309). Red needles (from HOAc), sol. aqueous  $NaHSO_3$ , v. sl. sol. alcohol and ether. Yields pyrene on distillation with zinc-dust. Bromine forms  $C_{16}H_8Br_2O_2$  and  $C_{16}H_8Br_4O_2$ . Its alcoholic solution is turned claret-colour by a little NaOH. Reduced by zinc-dust and ammonia to hydropyrene-quinone or pyrene-hydroquinone  $C_{16}H_{10}O_2$ , which forms golden crystals exhibiting a dark-blue fluorescence in alcoholic solution, and yielding  $C_{16}H_8Ae_2O_2$  [167°].

**PYRENE SULPHONIC ACID**  $C_{16}H_8SO_3H$ . Got by fusing the disulphonic acid with potash (Goldschmiedt a. Wegscheider, *M.* 4, 242). —  $KA'$  aq: minute needles (from dilute alcohol).

#### PYRENE DISULPHONIC ACID

$C_{16}H_8(SO_3H)_2$ . Formed by heating pyrene with  $H_2SO_4$ . Sticky mass, v. sol. water, sl. sol. alcohol, insol. ether. —  $KA'$  2½aq. —  $BaA'$  3½aq. —  $CaA'$  2aq: yellow powder.

#### PYRENIC ACID $C_{16}H_8O_4$ i.e.

Formed by the oxidation of pyrene or pyrene-quinone by chromic acid (Bamberger a. Philip, *B.* 19, 1427, 1995, 3036; 20, 369; *A.* 240, 168). Pale-yellow plates, blackened above 250°. V. sl. sol. alcohol.  $H_2SO_4$  forms an orange solution. Oxidised by  $KMnO_4$  to naphthalene tetra-carboxylic acid. Reacts with hydroxylamine. Phenyl-hydrazine forms  $C_{16}H_8O_4(N_2Ph)_2$  2aq, crystallising in yellow prisms. —  $BaA''$  aq. —  $Ag_2A''$ : amber-yellow pp.

**Anhydride**  $C_{16}H_8O \begin{smallmatrix} CO \\ < \\ CO \end{smallmatrix} > O$ . Yellow needles, formed by boiling the acid with HOAc.

**Imide**  $C_{16}H_8O \begin{smallmatrix} CO \\ < \\ CO \end{smallmatrix} > NH$ . Yellow plates, got by dissolving the acid in  $NH_4Aq$ .

**PYRENOLINE**  $C_{16}H_{11}N$ . [153°]. Formed by heating amido-pyrene hydrochloride with nitrobenzene, glycerin, and  $H_2SO_4$  (Jahoda, *M.* 8, 442). Golden scales (from alcohol), v. sol. water, forming solutions which exhibit green fluorescence. —  $B'HCl$ . [270°]. —  $B'H_2P'Cl$ . [above 290°]. —  $B'H_2SO_4$  aq. [246°]. —  $B'C_2H_5N_2O_2$ . Decomposes at 260°. —  $B'Mel$ . [212°].

**PYRIDANTHRILIC ACID**  $C_{16}H_8N_2O_2$  i.e.  $[2:1]CO_2H.C_6H_4.NH.CO.C_6H_4.N(CO_2H)_2$ . [265°]. Formed by the action of alkaline  $KMnO_4$  on cyclothraustic acid derived from  $\alpha$ -diquinoline (Weidel a. Strache, *M.* 7, 289; 8, 197). Micaceous plates, sl. sol. hot water. Yields isoscinchomeric and anthranilic acids on oxidation.

**PYRIDAZINE**. The ring  $CH \begin{smallmatrix} N=N \\ < \\ CH \end{smallmatrix} > CH$  (Ach, *A.* 253, 46; cf. Knorr, *A.* 236, 295).

**PYRIDINE**  $C_5H_5N$  i.e.  $N \begin{smallmatrix} CH:CH \\ < \\ CH:CH \end{smallmatrix} > CH$ .

Mol. w. 79. (116°) (Schiff, *B.* 19, 566); (114°) (Ladenburg, *A.* 247, 4); (116.5°) (Perkin, *C. J.* 55, 701). S.G.  $\frac{1}{4}$  1.0033 (*L.*);  $\frac{1}{2}$  .9855;  $\frac{3}{4}$  .9778 (*P.*). M.M. 8.761. H.F.p. — 19.370 (Thomsen); 7.117 (Ramsay, *C. J.* 35, 696). H.F.v. — 20.530 (Thomsen, *Th.*). S.H. .418 (Colson, *A. Ch.* [6] 19, 408). S.V. 89.4 (Schiff); 91.6 (Ramsay). Occurs in bone oil, in coal-tar, and in tar got by distilling bituminous shale and peat (Anderson, *Tr. E.* 16, 4; 20 [2] 247; *P. M.* [4] 2, 257; *A.* 80, 55; 96, 200; 105, 335; Greville Williams, *P. M.* [4] 8, 24; Church a. Owen, *C. N.* 2, 146; *P. M.* [4] 20, 110; Schulze, *B.* 20, 409). Occurs also in tobacco smoke, and, in small quantity, in fusel oil (Haitinger, *M.* 3, 688).

**Formation**. — 1. By heating isocamyl nitrate with  $P_2O_5$  (Chapman a. Smith, *A. Suppl.* 6, 829). 2. By distilling its carboxylic acids with lime. — 3. By distilling oxytrialdine and oxytetraldine with soda-lime (Schiff, *A. Suppl.* 6, 21). — 4. With other bases by heating glycerin with ammonium phosphate (Stöhr, *J. pr.* [2] 45, 23). — 5. By passing ethyl-allyl-amine over  $PbO$  at 450° (Koenigs, *B.* 12, 2344). — 6. By heating piperidine with  $H_2SO_4$  at 300° (K.), with nitrobenzene ( $\frac{4}{3}$  pts.) at 260° (Leilmann a. Geller, *B.* 21, 1921), or with  $AgOAc$  and 10 p.c. HOAc at 180° (Tafel, *B.* 25, 1621). — 7. Together with mono- and disubstitution products by the action of Br on

**Reactions.**—1. Dry chlorine forms di-chloropyridine [72°]. Chlorine passed into a solution of pyridine in  $\text{CHCl}_3$  forms  $\text{B'Cl}_2$ , a white powder (Bally, B. 21, 1772). Chlorine-water ppts. a white powder.  $\text{KOC}$  completely decomposes pyridine, forming  $\text{N}$ ,  $\text{CO}$ ,  $\text{CHCl}_3$ , and chloro-acetic acid (Keiser, Ann. 8, 308).—2. Bromine added to a solution of the hydrochloride ppts.  $\text{C}_5\text{H}_5\text{NBr}$ , which is split up by heat into pyridine and bromine. Bromine acting in the cold on pyridine and water gives rise to  $(\text{C}_5\text{H}_5\text{NBr})_2\text{HBr}$  [126°] (Grimaux, Bl. [2] 38, 127). Pyridine hydrochloride heated with  $\text{Br}$  at 200° forms mono- and di-bromo-pyridine.—3.  $\text{HIAq}$  at 800° yields *n*-pentane and  $\text{NH}_3$  (Hofmann, B. 16, 590).—4. Sodium at 80° yields ( $\gamma$ )-dipyrilid  $\text{C}_{10}\text{H}_8\text{N}_2$ , dipyrindine  $\text{C}_{10}\text{H}_8\text{N}_2$ , isonicotine  $\text{C}_8\text{H}_8\text{N}_2$ , and two nitrogenous oils (240°–260°) and (300°–310°) (Weidel a. Russo, M. 8, 884).—5. Its alkylo-iodides are converted by distillation with solid  $\text{KOH}$  into volatile bases.—6. Excess of  $\text{AcCl}$  forms dehydracetic acid (Dennstedt a. Zimmermann, B. 19, 75).—7. Unites with  $\text{CH}_3\text{Cl.OH}$  (the product of the union of formic aldehyde and  $\text{HCl}$ ), and the product in aqueous solution gives with  $\text{HgCl}_2$  a pp. of  $(\text{C}_5\text{H}_5\text{N})(\text{CH}_3\text{Cl.OH})\text{HgCl}$  [162°], with platinum chloride a pp. of  $(\text{C}_5\text{H}_5\text{N})(\text{CH}_3\text{Cl.OH})_2\text{PtCl}$  [216°], and with picric acid the compound  $(\text{C}_5\text{H}_5\text{N})(\text{CH}_3\text{Cl.OH})_3\text{O}$  [c. 200°]. Treatment with  $\text{AgNO}_3$  forms  $(\text{C}_5\text{H}_5\text{N})\text{CH}_2(\text{OH})\text{NO}_2$ , crystallising from alcohol-ether in prisms (Hemmelmayer, M. 12, 633).—8. Allozan and aqueous  $\text{SO}$  form triclinic crystals of  $\text{B'C}_5\text{H}_5\text{N.O.H}_2\text{SO}$  (Pellizzari, A. 248, 150).—9. *Glycolic chlorhydrin* forms the base  $\text{C}_5\text{H}_5\text{NO}$  (Coppola, G. 15, 331). *Glycerin chlorhydrin* reacts with formation of  $\text{C}_5\text{H}_5\text{NClCl}_2\text{C}_2\text{H}_4(\text{OH})$ , [107°] separating from alcohol in hexagonal crystals and yielding  $(\text{C}_5\text{H}_5\text{N.O.Cl})\text{PtCl}$ , [180°] and  $\text{C}_5\text{H}_5\text{N.O.ClAcCl}$ , [122°] (Krüger, J. p. [2] 44, 180).—10. *Chloroacetic acid* at 100° forms  $\text{C}_5\text{H}_5\text{NClCl.C.O.H}$

Acetate  $B'3HOAc$ . (140°). Miscible with

water, forming an acid solution (Gardner, *B.* 23, 1588).—Formate  $B'3CH_3O_2$ . (149°). Liquid, v. sol. water.—Propionate  $B'3C_2H_5O_2$ . (149°). Liquid.—Cupric oxalate compound  $B'_2CuC_2O_4$ ; minute prisms (Seubert a. Rauter, *B.* 25, 2825).

**Methylo-chloride**  $B'MeCl$ . White needles (Ostermayer, *B.* 18, 591). Converted by a hot aqueous solution of picric acid into  $B'MeOC_6H_3(NO_2)_3$ , which crystallises in greenish-yellow explosive needles [34°].— $B'_2Me_2PtCl_6$ . [188°] (O); [207°] (B).— $B'_2Me_2AuCl_6$ . [253°].— $B'MeCHCl_2$ . [82°] (O); [90°] (B). Yellow plates.— $B'MeCHCl_3$ . [180°]. Unstable yellow crystals (Bally, *B.* 21, 1774).

**Methylo-perbromide**  $B'MeBr_2$ . [48°].

**Methylo-iodide**  $B'MeI$ . Converted at 290° into methyl-pyridine hydriodides. On heating with alcoholic potash at 45° it yields a brown resin, forming a deep-red solution in alcohol, turned bright-red by HCl, orange-red by acetic acid, and ruby-red by ammonia (O. de Coninck, *C. R.* 102, 1479). Chlorine forms  $B'MeICl_2$  [30°] (v. supra). Oxidised by alkaline  $K_2FeCy_6$  to oxy-methyl-pyridine or  $\nu$ -methyl-pyridone  $CH<\begin{smallmatrix} CH.CO \\ CH:CH \end{smallmatrix}>NMe$  (250°), a liquid miscible with water (Decker, *J. pr.* [2] 47, 28; cf. Pechmann, *B.* 24, 3144).

**Ethyl-iodide**  $B'EtI$ . Silvery tables (Anderson, *A.* 94, 364). At 300° it yields pyridine,  $NH_3$ , (a) and ( $\gamma$ )-ethyl-pyridine, and diethyl-pyridine (Ladenburg, *B.* 16, 2059; 18, 2961). Yields  $B'Et.PtCl_6$ . Oxidised by alkaline  $K_2FeCy_6$  to  $CH<\begin{smallmatrix} CH.CO \\ CH:CH \end{smallmatrix}>NEt$  (250°).

**Ethylene-iodide**  $B'C_2H_4I_2$ . Prisms (Coppola, *G.* 15, 832).  $Ag_2O$  yields a base  $C_2H_4NO$ . By heating pyridine with ethylene bromide and some alcohol at 100° there is found  $B'_2C_2H_4Br_2$ , which yields  $B'_2C_2H_4PtCl_6$  (Davidson, *A.* 121, 254).

**Benzoylo-chloride**  $B'PhCH_2Cl$ . Reduced by sodium-amalgam to the unstable  $C_6H_5N_2$  (Hofmann, *B.* 14, 1503).—( $B'PhCH_2Cl$ ). $PtCl_6$ .

**Nitro-benzoylo-chlorides**  $B'C_6H_4(NO_2).CH_2Cl$ . o [a 76°], m [70°–100°], p [90°–100°]. These bodies are reduced by tin and HClAq to  $B'_2C_6H_4(NH_2Cl).CH_2Cl$ , which are split up by heat into pyridine hydrochloride and  $C_6H_5<\begin{smallmatrix} NH_2Cl \\ CH_2 \end{smallmatrix}$  (Lellmann a. Pekrun, *A.* 259, 54).

**Phenacylo-bromide**  $B'BzCH_2Br$ . Prisms (Bamberger, *B.* 20, 3344).— $B'_2(BzCH_2).CrO_3$ .

**References.**—BROMO-, CHLORO-, OXY-AMIDO-, and OXY-PYRIDINE.

**Dipyridine**  $C_{10}H_{10}N_2$ . v. DIPYRIDYL DIHYDRIDE.

**Dipyridine**  $C_{10}H_{10}N_2$ . (275°). S.G. 1.124. Is probably a dipyridyl dihydride. Formed by heating nicotine with KOH and  $K_2FeCy_6$ , and also by heating the product of the action of S on nicotine at 150° with finely-divided copper (Cahours a. Etard, *Bl.* [2] 34, 452). Inactive liquid.— $B'_2HHgCl_2$ .— $B'_2H.PtCl_6$ . 2aq.— $B'_2H_2FeCy_6$ . 2aq.; brownish-green tables.

(a)-PYRIDINE CARBOXYLIC ACID

$C_6H_5NO_2$ , i.e.  $CH:CH.C_6H_4.CO_2H$ . Picolinic acid.

[186°]. Formed by oxidation of ( $\alpha$ )-methyl-pyridine with  $KMnO_4$  (Weidel, *B.* 12, 1994), and by oxidation of ( $\alpha$ )-phenyl-pyridine (Skraup, *M.*

4, 477). Obtained also, together with its hexahydride, from comenamic acid by successive treatment with  $PCl_5$  and  $H_2SO_4$ , the resulting di-chloro-picolinic acid being reduced by heating for three days at 155° with HI dissolved in HOAc (Ost, *J. pr.* [2] 27, 285).

**Preparation.**—The three acids got by oxidation of crude methyl-pyridine from animal oil are converted into copper salts. Cupric pyridine ( $\alpha$ )-carboxylate is extracted by hot water. The residue is treated with  $H_2S$ , and the difficultly-soluble ( $\gamma$ )-acid separated from the ( $\beta$ )-acid (Ost, *J. pr.* [2] 27, 286).

**Properties.**—Needles, v. sol. water and alcohol, almost insol. ether, benzene,  $CHCl_3$ , and  $CS_2$ . May be sublimed.  $FeSO_4$  gives a red colouration with picolinic acid and with all the carboxylic acids of pyridine that contain  $CO_2H$  in the ( $\alpha$ )-position (Skraup, *M.* 7, 210). The absorption of the ultra-violet spectrum has been studied by Hartley (*C. J.* 41, 45).

**Reactions.**—1. Yields pyridine on distillation with lime or with alcoholic potash at 240°. The Cu salt on distillation gives pyridine and ( $\alpha$ )-dipyridyl [70°] (Blau, *M.* 10, 375; *B.* 21, 1077).

—2. Sodium-amalgam forms 8-oxy-adipic acid (Weidel, *M.* 11, 522).—3. Fuming HI at 170° forms ( $\alpha$ )-methyl-pyridine and piperidine (Seylforth, *J. pr.* [2] 34, 241).—4. Zinc-dust and HOAc reduce it to ( $\alpha$ )-methyl-pyridine.

**Constitution.**—This may be deduced from its formation from ( $\beta$ )-naphthoquinoline *via* ( $\beta$ )-phenyl-pyridine carboxylic acid (Skraup a. Co-benzl, *M.* 4, 436).

**Salts.**— $HA'HCl$ : unstable crystals.— $H_2A'_2H.PtCl_6$ . 2aq.: orange-red crystals.— $NH_4A'$ : triclinic tables.— $KA'$ .— $BaA'_2$ . 3aq.— $CaA'_2$ . aq.— $MgA'_2$ . 2aq.

**Hexahydride**  $C_6H_8N.CO_2H$ . Piperidine ( $\alpha$ )-carboxylic acid. The chief product of the action of HI at 160° on mono- or di-chloro-picolinic acid (Ost, *J. pr.* [2] 27, 287). Got also by reducing picolinic acid (Ladenburg, *B.* 24, 640). Syrup, v. sol. water. Salts.— $B'HCl$ . [264°]. Nodules.— $B'_2H.PtCl_6$ . [184°] (L).— $B'_2H_2PtCl_6$ . 2aq.— $B'MeCl$ . [191°]. Needles.

**Pyridine ( $\beta$ )-carboxylic acid**

$CH:CH.C_6H_4.CO_2H$ . Nicotinic acid. [230°].

$CH: N.CH$

**Formation.**—1. By oxidising nicotine with  $HNO_3$  (Weidel, *A.* 165, 330),  $CrO_3$  (Huber, *A.* 141, 271; *B.* 3, 849), or  $KMnO_4$  (Laiblin, *A.* 196, 129).—2. A product of oxidation of coal-tar bases (Weidel; Mohler, *B.* 21, 1009).—3. By heating quinolinic acid at 160° or with HCl at 180° (Ost, *J. pr.* [2] 27, 286; Lippmann a. Fleissner, *M.* 8, 315).—4. By oxidation of ( $\beta$ )-methyl-pyridine (Weidel, *B.* 12, 2004), ( $\beta$ )-ethyl-pyridine (Stoehr, *J. pr.* [2] 43, 155) or ( $\beta$ )-phenyl-pyridine (Skraup, *M.* 4, 453).—5. By saponification of its nitrile, which is got by distilling sodium-pyridine sulphonate with  $KCy$  (Fischer, *B.* 15, 63).—6. By heating three of the pyridine dicarboxylic acids (Hoogewerff a. Van Dorp, *R. T. C.* 1, 1, 107; *A.* 204, 117; 207, 226; Weidel a. Herzog, *M.* 1, 16).—7. By heating berberonic acid at 215° (Fürth, *M.* 2, 420).—8. By the action of Zn and HClAq on chloro-nicotinic acid (Pechmann a. Welsh, *C. J.* 47, 145).

**Properties.**—Needles, aq. sol. cold water, sol. alcohol, nearly insol. ether. May be sublimed.

**Reactions.**—1. Yields pyridine on distillation with lime.—2. Sodium-amalgam yields a mixture of 8-oxy- $\alpha$ -methyl-glutaric acid and its lactone, which, on treatment with alcohol and HCl, yields a mixture of two ethers. One of these,  $C_{10}H_{11}ClO_4$ , is converted by sodium-amalgam into  $\alpha$ -methyl-glutaric acid, and the other,  $C_8H_{11}O_4$ , is also converted by successive treatment with PI and with Zn and dilute  $H_2SO_4$  into  $\alpha$ -methyl-glutaric acid (Weidel, *M.* 11, 502).—3. Bromine and water at 120° yield  $CO_2$ , pyridine, and bromoform.—4. The K salt heated with MeI at 150° forms  $C_8H_9NMe.CO.Me$ , which on saponification yields  $C_8H_9NMe(OH).CO_2H$  [130°], converted at 100° into trigonellin  $C_8H_9NMe \begin{smallmatrix} \diagup CO \\ \diagdown \end{smallmatrix}$  [218°], which occurs in the seeds of *Trigonella farnum gracum* (Jahns, *B.* 18, 2521; Hantzsch, *B.* 19, 31). This anhydride forms the salts  $C_8H_9NO.HCl$ ,  $B'H.PtCl_6$ , aq.,  $B'HAuCl_4$  [198°], and  $B',3HAuCl_4$  [186°].

**Constitution.**—This may be deduced from its formation from (a)-naphthaquinoline *vid* (a)-phenyl-pyridine carboxylic acid.

**Salts.**— $HA'HCl$ . Colourless prisms.— $H_2A',H.PtCl_6$  2aq.— $B',H.AuCl_4$ .— $B'HNO_3$  aq.— $NH_4A'$ : needles.— $KA'$ .— $MgA'$ : needles.— $CaA'$  5aq: monoclinic crystals; *a:b:c* = 1.537:1:0.629;  $\beta$  = 62° 50'.— $Cu(OH)A'$  (De Coninck, *B.* [2] 42, 100).— $AgA'$ : needles (from hot water).

**Nitrile**  $C_8H_9N.Cy$ . [49°]. Formed by distilling sodium pyridine sulphonate with KCy (Fischer, *B.* 15, 63). Needles or prisms, sol. water.— $B'HCl$ .— $B',H.PtCl_6$ : yellow soluble needles. Tables (by sublimation). Converted by means of hydroxylamine into the amidoxim  $C_8H_9N.C(NH_2)NOH$  [128°], which yields an acetyl derivative [143°] and a benzoyl derivative [190°], and is converted by phenyl cyanate into  $C_8H_9N.C(NOH).NH.CO.NHPh$  [167°], by phenyl thiocarbimide into  $C_8H_9N.C \begin{smallmatrix} \diagup N.S \\ \diagdown \end{smallmatrix} > C.NHPh$  [241°], and by succinic anhydride at 100° into  $C_8H_9N.C \begin{smallmatrix} \diagup N.O \\ \diagdown \end{smallmatrix} > C.CH_2.CH_2.CO_2H$  [178°]. The acetyl and benzoyl derivatives are converted by heating into  $C_8H_9N.C \begin{smallmatrix} \diagup N.O \\ \diagdown \end{smallmatrix} > CMe$  [109°] and  $C_8H_9N.C \begin{smallmatrix} \diagup N.O \\ \diagdown \end{smallmatrix} > CPh$  [139°] respectively (Michaëlis, *B.* 24, 3439).

**Hexahydrate**  $C_8H_9N.CO_2H$ . *Nipicotinic acid*. [250°]. Got by reducing nicotinic acid in alcoholic solution by Na (Ladenburg, *B.* 25, 2763). Crystals, v. e. sol. water, insol. alcohol and ether.— $HA'HCl$ . [240°].— $H_2A',H.PtCl_6$ . [218° cor.].— $HA'HAuCl_4$ . [197° cor.].— $HA'HCl5HgCl_2$ . [231°].— $MeA'HCl$  [208°].— $Me_2A',H.PtCl_6$ .—Nitrosamine  $C_8H_9N_2O_2$ . [112°].

**Pyridine ( $\gamma$ )-carboxylic acid**

$N \begin{smallmatrix} \diagup CH.CH \\ \diagdown \end{smallmatrix} > C.CO_2H$ . *Isonicotinic acid*. [305°] (S.). [306°] (B. a. H.); [309.5°] (W. a. H.).

**Formation.**—1. By heating pyridine  $\alpha$ -tricarboxylic acid (Skraup, *B.* 12, 2331) and three of the pyridine di-carboxylic acids (Hoogewerff a. Van Dorp, *A.* 204, 112; Weidel a. Herzig, *M.* 1, 23; Böttinger, *B.* 38, 68).—2. By the action of  $KMnO_4$  on ( $\gamma$ )-methyl-pyridine (Behrmann a. Vol. IV.

Hofmann, *B.* 17, 2696; Ladenburg, *B.* 21, 287). 3. By heating di-chloro-pyridine carboxylic acid [210°] with HI (B. a. H.).

**Properties.**—Needles, sl. sol. cold water, insol. alcohol. Yields pyridine on distilling with lime and 8-oxy-ethyl-succinic acid on reduction with sodium-amalgam (Weidel, *M.* 11, 517).

**Salts.**— $NH_4A'$ : needles.— $CaA'$  4aq: silky needles, m. sol. water.— $HA'HCl$ : monoclinic prisms.— $H_2A',H.PtCl_6$  2aq: monoclinic crystals.

**Hexahydrate**  $C_8H_9N.CO_2H$ . Got by reducing the acid in alcoholic solution by Na (Ladenburg, *B.* 25, 2773). Branching groups of needles, v. e. sol. water, insol. alcohol. Blackens at 300°, but is not melted at 320°.— $HA'HCl$ . [228°]. Trimetric crystals; *a:b:c* = 0.923:1:0.979.— $H_2A',H.PtCl_6$ . [239°].—Aurochloride: [197°]. Nitrosamine  $C_8H_9N_2O_2$ . [101°].

**Pyridine ( $\alpha\alpha$ )-dicarboxylic acid**

$CH \begin{smallmatrix} \diagup CH.C(CO_2H) \\ \diagdown \end{smallmatrix} > N$ . *Dipicolinic acid*. [226°]

(L. a. R.; S.); [237°] (E.); [236° cor.] (Collie, *C. J.* 59, 179). Formed by oxidation of ( $\alpha\alpha$ )-dimethyl-pyridine [145°] (derived from acetoacetic ether or from coal-tar) by  $KMnO_4$  (Epstein, *A.* 231, 26; Ladenburg a. Roth, *B.* 18, 52; 19, 790; 20, 130; A. 247, 32; Lange a. Rosenberg, *B.* 20, 132; cf. Dewar, *C. N.* 23, 18). Got also by oxidation of ( $\alpha$ )-methyl-( $\alpha$ )-ethyl-pyridine by dilute (2 p.c.)  $KMnO_4$  (Schultz, *B.* 20, 2734).

**Properties.**—Hair-like needles (containing 1½ aq) or anhydrous scales; sl. sol. cold alcohol, water, and ether. On heating at 245° in a current of H it yields pyridine and pyridine ( $\alpha$ )-carboxylic acid.  $PCl_5$  forms a chloride [61°], (284°).  $FeSO_4$  gives a reddish-yellow colour.

**Salts.**— $CaA'$  2aq: minute prisms.— $CaA'$  2aq: dark-blue prisms.

**Pyridine ( $\alpha\beta$ )-dicarboxylic acid**

$C(CO_2H).C(CO_2H) \begin{smallmatrix} \diagup CH=CH \\ \diagdown \end{smallmatrix} > N$ . *Quinolinic acid*. [281°].

S. 55 at 6.5°. Formed by the oxidising action of  $KMnO_4$  on quinoline (Hoogewerff a. van Dorp, *B.* 12, 747; *R. T. C.* 1, 107; A. 204, 117), on cinchonine (II. a. D.), on o- and p-methyl-quinoline (Skraup, *M.* 2, 157), on o-oxy-quinoline, on quinoline o-sulphonic acid (O. Fischer a. Benouf, *B.* 17, 755), and on ( $\alpha$ )-oxy-quinoline carboxylic acid (La Coste a. Valeur, *B.* 20, 103).

**Properties.**—Monoclinic needles, *a:b:c* = .542:1: .607;  $\beta$  = 64° 54'; sl. sol. water and alcohol, insol. ether. Begins to decompose at 140°, and forms nicotinic acid. Yields pyridine when distilled with lime. Reduced by sodium-amalgam to the 8-lactone of butane  $\alpha\beta\gamma$ -tricarboxylic acid  $CH_2.CH_2.CH.CO_2H$  (Perlmutter, *M.* 13, 840).

**Salts.**— $KHA'$  2aq: triclinic plates (Lippmann a. Fleissner, *M.* 8, 311).— $KA'$  2aq.— $BaA'$  aq.— $AgA'$ : crystalline.— $AgHA'$  aq.

**Anhydride**  $C_8H_9N \begin{smallmatrix} \diagup CO \\ \diagdown \end{smallmatrix} > O$ . [185°]. Got

from the acid and  $Ac_2O$  (Bernthsen a. Mettengang, *B.* 20, 1208). Prisms. Converted by benzene and  $AlCl_3$  into  $C_8H_9BzN.CO_2H$  [147°], converted by heat into the ketone  $C_8H_9BaN$  (307° uncor.), which yields a crystalline phenylhydrazide [143.5°].

**Pyridine ( $\alpha\gamma$ )-dicarboxylic acid**

$CO_2H.C \begin{smallmatrix} \diagup CH.C(CO_2H) \\ \diagdown \end{smallmatrix} > N$ . *Lutidinic acid*.

[240°] (V.); [235°] (B.; L. a. R.). Formed by the oxidising action of  $\text{KMnO}_4$  on ( $\alpha$ )-dimethyl-pyridine (Ramsay, *P. M.* [5] 4, 241; 6, 19; Weidel a. Horzig, *M.* 1, 20; Ladenburg a. Roth, *B.* 18, 915; A. 247, 87), on ( $\alpha$ )-methyl-( $\gamma$ )-ethyl-pyridine (Schultz, *B.* 20, 2726), on diethyl-pyridine, on ( $\alpha\alpha$ )-di-methyl-dipyridyl (Heuser a. Stoehr, *J. pr.* [2] 44, 409), and on the methyl-pyridine carboxylic acid obtained from uvitonic acid (Böttinger, *B.* 14, 68; 17, 93; Voigt, *A.* 228, 54).

**Properties.**—Needles (containing aq), m. sol. cold water, sol. alcohol, insol. ether. Gives a blood-red colour with  $\text{FeSO}_4$ . Yields pyridine on distillation with lime. Converted by heat into  $\text{CO}_2$  and isonicotinic acid.  $\text{PCl}_5$  yields a chloride [203°].

**Salts.**— $\text{KHA}''$  1/2 aq. Crystals.— $(\text{NH}_4)_2\text{A}''$ — $(\text{NH}_4)\text{HA}''$  aq; hygroscopic needles.— $\text{CaA}''$  3 aq.— $\text{CaA}''$  aq.— $\text{CaA}''$  1/2 aq.— $\text{CaH}_2\text{A}''$  2 aq.— $\text{BaA}''$  aq.— $\text{BaA}''$  1 1/2 aq (B.).— $\text{BaA}''$  3 aq.— $\text{CdA}''$  4 aq (Waage, *M.* 4, 727).— $\text{MgA}''$  5 aq.— $\text{CuA}''$  3 aq.— $\text{CuA}''$  4 aq (B.).— $\text{AgA}''$  2 aq: white pp.

**Pyridine ( $\alpha\beta$ )-dicarboxylic acid**

**Formation.**—1. By oxidation of lutidine (150°–170°) with  $\text{KMnO}_4$  (Ramsay, *P. M.* [5] 4, 246; Weidel a. Herzog, *M.* 1, 1; Lange a. Rosenberg, *B.* 20, 185).—2. By oxidising ( $\beta'$ )-methyl-( $\alpha$ )-ethyl-pyridine (Ladenburg, *A.* 247, 44).—3. By oxidation of quinine (Ramsay a. Dobbie, *C. J.* 33, 102; *B.* 11, 324).—4. By heating the dihydride of potassium pyridine tricarboxylate (Weiss, *B.* 19, 1311).—5. By the action of alkaline  $\text{KMnO}_4$  on cyclothraustic acid and on pyridanthrilic acid (Weidel a. Strache, *M.* 7, 290).—6. By oxidising ( $\beta$ )-ethyl-( $\alpha$ )-stilbazole (Plath, *B.* 22, 1062).

**Properties.**—Small prisms (containing aq), almost insol. cold water, alcohol, and benzene, sol. hot  $\text{HCl}$  aq. On heating with  $\text{HOAc}$  at 220° it is split up into  $\text{CO}_2$  and nicotinic acid [230°]. On heating with lime it gives pyridine.  $\text{PCl}_5$  yields a chloride [61°] converted by  $\text{NH}_3$  into an amide [297°].  $\text{FeSO}_4$  gives a reddish colour.

**Salts.**— $(\text{NH}_4)\text{HA}''$  aq. [253°]. Triclinic prisms, sl. sol. cold water.— $(\text{NH}_4)_2\text{A}''$ — $\text{KHA}''$  1/2 aq: needles.— $\text{KA}''$  aq.— $\text{CaA}''$  2 aq.— $\text{Ca}(\text{HA}'')$  3 aq.— $\text{MgA}''$  5 aq.— $\text{CuA}''$  aq.— $\text{Ag}_2\text{A}''$ . *Methyl ether MeA''*. [117.5°] (R.).

**Pyridine ( $\beta\beta'$ )-dicarboxylic acid**

Formed by heating pyridine (2,3,5)-tri-carboxylic acid and pyridine (2,3,5,6)-tetra-carboxylic acid (Riedel, *B.* 16, 1613; Hantzsch a. Weiss, *B.* 19, 286; Weber, *A.* 241, 12). Formed also by heating di-chloro-pyridine di-carboxylic acid with conc.  $\text{HIAc}$  at 180° (Guthzeit, *A.* 262, 130).

**Properties.**—Small prisms (from  $\text{HOAc}$ ), split up by heat into  $\text{CO}_2$  and nicotinic acid.

**Salts.**— $\text{PbA}''$  2 aq.— $\text{Ag}_2\text{A}''$  aq.— $\text{AgA}''$  1 1/2 aq.— $\text{HA}''\text{HCl}$  2 aq: needles, decomposed by water.— $\text{HA}''\text{H}_2\text{PtCl}_6$ : orange-red needles.

**Pyridine ( $\beta\gamma$ )-dicarboxylic acid**

**Formation.**—1. By oxidation of cinchonine or cinchonidine by  $\text{HNO}_3$  of S.G. 1.4 (Weidel, *A.* 173, 76).—2. By oxidation of quinine by  $\text{HNO}_3$ , the yield being 28 p.c. (Weidel a. Schmidt, *B.* 12, 1146).—3. By heating apophyllenic acid with conc.  $\text{HCl}$  aq at 240° (Von Gerichten, *B.* 13, 1635).—4. By heating pyridine tricarboxylic acid (formed from cinchonine acid) at 190° (Hoogewerff a. van Dorp, *B.* 13, 61; Skraup, *M.* 1, 184; Weidel a. Brix, *M.* 3, 604).—5. By the action of  $\text{KMnO}_4$  on methyl-pyridine carboxylic acid and on isoquinoline (Hoogewerff a. van Dorp, *R. T. C.* 2, 23; 4, 285).—6. By heating pyridine pentacarboxylic acid (Weber, *A.* 241, 16).—7. By oxidation of methyl-nicotinic acid, derived from ( $\beta$ )-collidine (Oechsner de Coninck, *Bl.* [2] 43, 106).—8. By boiling berberonic acid with  $\text{HOAc}$  (2 pts.) and  $\text{Ac}_2\text{O}$  (1 pt.) for six hours (Mayer, *M.* 13, 844; cf. Fürth, *M.* 2, 426).

**Properties.**—Prisms (from  $\text{HCl}$  aq), v. sl. sol. water and ether, sl. sol. alcohol. Yields isonicotinic and some nicotinic acid on heating (Hoogewerff a. van Dorp, *A.* 207, 217). Gives pyridine on distillation with lime. Sodium-amalgam yields  $\text{NH}_3$  and cinchonine acid  $\text{C}_9\text{H}_9\text{O}_6$ , i.e.  $\text{CO}_2\text{H} \begin{array}{c} \text{CH}_2\text{CO} \\ \text{CH} \end{array} \text{CH}_2 \text{O}$  (Weidel a. Hoff, *M.*

13, 578). Cinchonine acid [169°] forms monoclinic crystals, v. sol. hot water and alcohol, and yields  $\text{BaC}_9\text{H}_9\text{O}_6$  3 aq,  $\text{Ba}_2(\text{C}_9\text{H}_9\text{O}_6)_2$  3 aq,  $\text{CaA}''$  2 aq,  $\text{Ca}(\text{C}_9\text{H}_9\text{O}_6)_2$  (dried at 190°), and oily  $\text{Et}_2\text{A}''$ , whence  $\text{PCl}_5$  followed by alcohol, yields  $\text{CO}_2\text{Et} \cdot \text{CH}(\text{CH}_2\text{Cl}) \cdot \text{CH}(\text{CO}_2\text{Et}) \cdot \text{CH}_2 \cdot \text{CO}_2\text{Et}$ , which is a heavy oil. Cinchonine acid is reduced by  $\text{HI}$  to butane tricarboxylic acid  $\text{C}_4\text{H}_9\text{O}_6$  [184°], whence  $\text{Ca}_2\text{A}''$  8 aq, accompanied by an isomeric butane tricarboxylic acid [138°].  $\text{FeSO}_4$  gives no colour.

**Salts.**— $\text{Na}_2\text{A}''$  2 aq: tables.— $\text{NaHA}''$ .— $\text{BaA}''$  1 1/2 aq: needles, sl. sol. water.— $\text{CaA}''$  3 aq: prisms.— $\text{CaA}''$  3 aq.— $\text{CaA}''$  3 aq: small blue crystals.— $\text{Ag}_2\text{A}''$ : white pp.— $\text{AgHA}''$ .— $\text{HA}''\text{HCl}$ : monoclinic prisms, decomposed by water.— $\text{HA}_2\text{H}_2\text{PtCl}_6$ : golden prisms.

**Anhydride** ( $\text{C}_9\text{H}_7\text{N})_2\text{O}_3$ . [77°]. Formed by boiling the acid with  $\text{Ac}_2\text{O}$  (Goldschmidt a. Strache, *M.* 10, 156). Plates. May be sublimed. Converted by  $\text{NH}_3$  gas into  $\text{C}_9\text{H}_7\text{N}(\text{CO}_2\text{NH}_2)_2$ ,  $\text{CONH}_2$  [229°], which is converted by heat into a yellow powder [130°], and which yields the amic acid  $\text{C}_9\text{H}_7\text{N}(\text{CO}_2\text{H})\text{CONH}_2$  [237°], crystallising in needles.

**Mono-ethyl ether  $\text{HEtA}''$** . [183°]. Formed from the anhydride and  $\text{EtOH}$ . Plates (from benzene).— $\text{AgEtA}''$ : long needles.

**Mono-methyl ether  $\text{HMeA}''$** . [154°].

**Anhydride of the Methylhydroxide**

$\text{C}_9\text{H}_7\text{NO}$ , i.e.  $\text{C}_9\text{H}_7\text{NMe}(\text{CO}_2\text{H}) \begin{array}{c} \text{CO} \\ \text{O} \end{array}$ . **Apophyllenic acid** [242°]. Formed by oxidation of cotarnine by  $\text{HNO}_3$  (Wöhler, *A.* 50, 24; Anderson, *Tr. E.* 23, 347; *C. J.* 5, 257; Gerichten, *B.* 13, 1635). Formed also by heating cinchomeronic acid with  $\text{MeI}$  and  $\text{MeOH}$  at 100° (Rosser, *A.* 234, 116). Needles (anhydrous) or octahedra (containing aq), sol. hot water, insol. alcohol and ether.  $\text{HCl}$  aq at 250° decomposes it, forming cinchomeronic acid and  $\text{MeCl}$ .— $\text{BaA}''$ .— $\text{AgA}''$ .— $\text{Ag}_2\text{A}''(\text{NO}_3)_2$ .— $\text{HA}_2\text{H}_2\text{PtCl}_6$  aq.

**Bromo-apophyllenic acid**  
 $\text{C}_6\text{H}_4\text{BrNO}_2$ , 2aq. [205?]. Formed by oxidation of bromo-tarconine. Yields  $\text{BaA}'$ , 3aq and  $\text{H}_2\text{A}'$ ,  $\text{H}_2\text{PtCl}_4$  (Gerichten, A. 210, 91).

**Pyridine ( $\alpha\alpha'$ )-tricarboxylic acid**

$\text{CH} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{CH} \end{smallmatrix} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \text{N}$ . Formed by oxidising di-methyl-nicotinic acid with  $\text{KMnO}_4$  (Weiss, B. 19, 1309). Crystallises from alcohol in plates (containing 2aq), v. e. sol. water. Decomposes at  $160^\circ$  into  $\text{CO}_2$  and isocinchomeronic acid.  $\text{FeSO}_4$  colours its neutral solution red. —  $\text{KHA}'$ , 5aq; needles. —  $\text{CaA}''$ , 4aq. —  $\text{Pb}_2\text{A}''$ , 5aq.

**Pyridine ( $\alpha\alpha'$ )-tricarboxylic acid**

$\text{CO}_2\text{H.C} \begin{smallmatrix} \text{CH.C}(\text{CO}_2\text{H}) \\ \text{CH.C}(\text{CO}_2\text{H}) \end{smallmatrix} \text{N}$ . *Trimesitic acid*. *Carbohutidinic acid*. [244?]. Formed by oxidation of uvitonic acid (Böttiger, B. 13, 2048; 14, 69), and by oxidation of the tri-methyl-pyridine obtained from acetoacetic ether and aldehyde-ammonia (Voigt, A. 228, 31). Tables or spheroidal groups of needles (containing 2aq), sol. hot water, sl. sol. alcohol and ether. Yields isonicotinic acid on sublimation.  $\text{FeSO}_4$  gives a violet-red colour.

Salts. —  $\text{KA}'''$ , 5aq; needles. —  $\text{CaA}'''$ , 4aq. —  $\text{BaA}'''$ , 6aq. —  $\text{BaHA}'''$ , 4aq. —  $\text{Mg}_2\text{A}'''$ , 12aq. —  $\text{Cu}_2\text{A}'''$ , 12aq. —  $\text{Ag}_2\text{A}'''$ , 14aq.

**Ethyl ether  $\text{Et}_2\text{A}'''$ . [127-5?].**

*Amide*. [above  $280^\circ$ ].

**Pyridine ( $\alpha\beta\beta'$ )-tri-carboxylic acid**

$\text{CH} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{CH} \end{smallmatrix} \text{N}$ . *Carbodinicotinic acid*. [323?]. Formed by oxidation of quino-line (Py. 2)-carboxylic acid (Riedel, B. 16, 1615), of methyl-pyridine ( $\beta\beta'$ )-dicarboxylic acid (Weber, A. 241, 11), and of the parvoline got by heating propionic aldehyde-ammonia with propionic aldehyde at  $200^\circ$  (Dürkopt, B. 21, 832, 2707; 23, 689). Spherical aggregates (containing 1½aq), v. sol. hot water. At  $155^\circ$  it is split up into  $\text{CO}_2$  and dinicotinic acid. —  $\text{BaA}''$ , 5aq. —  $\text{Ag}_2\text{HA}''$ , 1½aq; rosettes of plates.

**Pyridine ( $\alpha\beta\gamma$ )-tri-carboxylic acid**

$\text{CO}_2\text{H.C} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{CH} \end{smallmatrix} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{CH} \end{smallmatrix} \text{N}$ . [250?] (H. a. D.; S.); [257?] (D. a. R.). S. 1·2 at  $15^\circ$ .

*Formation*. — 1. By the action of  $\text{KMnO}_4$  on quinine, cinchonine, cinchonidine, quinoidine, and cinchononic acid (Dobbie a. Ramsay, C. J. 35, 189; Hoogewerff a. van Dorp, B. 12, 158; 13, 152; A. 204, 84; Skraup, A. 201, 312; Strache, M. 10, 642). — 2. By oxidation of cinchonine by  $\text{HNO}_3$  (Weidel, A. 173, 101; B. 12, 415). — 3. By oxidation of methyl-pyridine ( $\alpha\beta$ )-dicarboxylic acid (Hoogewerff a. van Dorp, R. T. C. 2, 18), of di-methyl-pyridine dicarboxylic acid (Michael, B. 18, 2027), of ( $\alpha$ )-oxy-cinchonic acid (Weidel a. Cobenzl, M. 1, 865). — 4. By oxidation of papaverine (Goldschmiedt, M. 6, 397). Trimetric plates (containing 1½aq), v. sol. hot water, m. sol. alcohol, nearly insol. ether. Blackens at  $200^\circ$ .  $\text{FeSO}_4$  gives a reddish colour.  $\text{H}_2\text{S}$  forms a red amorphous body (D. a. R.). Decomposed by long heating at  $180^\circ$ , or by boiling with  $\text{HOAc}$  into  $\text{CO}_2$  and cinchomeronic acid. Yields pyridine on distilling with lime.  $\text{MeI}$  and  $\text{MeOH}$  at  $100^\circ$  form  $\text{CO}_2$  and apophyllenic acid. Sodium-amalgam gives  $\text{NH}_3$  and cinchononic acid.  $\text{PbCl}_2$  forms a chloride ( $206^\circ$  at 40 mm.).

Salts. —  $\text{KA}'''$ , 3aq. —  $\text{BaA}'''$ , 16aq. —

$\text{Ba}_2\text{A}'''$ , 12aq. —  $\text{Ca}_2\text{A}'''$ , 14aq. —  $\text{Ca}_2\text{A}'''$ , 13aq. —  $\text{CaHA}'''$ , 2½aq. —  $\text{Cu}_2\text{A}'''$ , 9aq; light-blue pp. —  $\text{CuHA}'''$ , 3½aq; hexagonal prisms. —  $\text{CuHA}'''$ , 2aq. —  $\text{Cd}_2\text{A}'''$ , 6aq. —  $\text{Ag}_2\text{HA}'''$ , 2½aq. —  $\text{Ag}_2\text{A}'''$ , 2aq; amorphous pp. —  $\text{AgHA}'''$ , 2½aq. —  $\text{H}_2\text{A}'''$ ,  $\text{HCl}$ ; crystalline powder (Roser, A. 234, 125).

**Pyridine ( $\alpha\beta\gamma$ )-tricarboxylic acid**

$\text{CO}_2\text{H.C} \begin{smallmatrix} \text{CH.C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \text{N}$ . *Berberonic acid*.

[243?]. Formed by oxidising berberine with nitric acid (Weidel, B. 12, 410; Fäth, M. 2, 416). Triclinic prisms (containing 2aq), sol. hot water, v. sl. sol. hot alcohol, insol. ether. Yields pyridine on distillation with lime.  $\text{FeSO}_4$  gives a red colour. At  $215^\circ$  it is split up into  $\text{CO}_2$  and nicotinic acid; above  $243^\circ$  it yields isonicotinic acid.

Salts. —  $\text{KA}'''$ , 4½aq. —  $\text{K}_2\text{HA}'''$ , 8aq. —  $\text{KHA}'''$ , 1½aq. —  $\text{Ca}_2\text{A}'''$ , 8aq. —  $\text{Cu}_2\text{A}'''$ , 4aq. —  $\text{Ag}_2\text{A}'''$ ; white pp., insol. water.

**Pyridine ( $\beta\beta'$ )-tricarboxylic acid**

$\text{CO}_2\text{H.C} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \text{CH} \text{N}$ . ( $\beta$ ) - *Carbocinchomeronic acid*. [261?].

Formed by heating dipotassium pyridine pentacarboxylate at  $220^\circ$  (Weber, A. 241, 17). Plates (containing 3aq), v. sol. hot water. Yields cinchomeronic acid when heated. Gives no colour with  $\text{FeSO}_4$ . —  $\text{Cu}_2\text{HA}'''$ , 2½aq. —  $\text{Ag}_2\text{A}'''$ , 2aq; crystalline pp.

**Pyridine ( $\alpha\beta\beta'$ )-tetra-carboxylic acid**

$\text{C}_6\text{H}_3\text{NO}_4$  i.e.  $\text{CO}_2\text{H.C} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{CH} \end{smallmatrix} \text{N}$ .

Formed by oxidising ( $\alpha\gamma$ )-di-methyl-pyridine ( $\beta\beta'$ )-dicarboxylic acid (Weber, A. 241, 23). Prisms (containing 2aq or 3aq). At  $120^\circ$  it loses  $\text{CO}_2$ , forming ( $\beta$ )-carbocinchomeronic acid.  $\text{FeSO}_4$  gives a dark-red colour. —  $\text{Ba}_2\text{A}''$ , 4aq. —  $\text{Ag}_2\text{HA}''$ , 1½aq; crystalline.

**Pyridine ( $\alpha\alpha'\beta\beta'$ )-tetra-carboxylic acid**

$\text{CH} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \text{N}$ . Formed by oxidising

di-methyl-pyridine dicarboxylic acid (Hantzsch, B. 19, 286; Weber, A. 241, 4). Needles (containing 2aq), v. sol. water. Decomposes at  $150^\circ$  into  $\text{CO}_2$  and dinicotinic acid. —  $\text{CaHA}''$ , 2aq; needles, v. sol. water. —  $\text{Cu}_2\text{A}''$ , 5aq. —  $\text{Ag}_2\text{A}''$ , 2aq; bulky pp.

**Pyridine ( $\alpha\alpha'\beta\gamma$ )-tetra-carboxylic acid**

$\text{CO}_2\text{H.C} \begin{smallmatrix} \text{CH} \\ \text{C}(\text{CO}_2\text{H}) \end{smallmatrix} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H}) \\ \text{CH} \end{smallmatrix} \text{N}$ . Formed by

oxidation of tri-methyl-pyridine carboxylic acid and of di-methyl-pyridine dicarboxylic acid (Michael, A. 225, 142). Formed also by oxidation of flavenol by alkaline  $\text{KMnO}_4$  (Fischer a. Tübler, B. 17, 2927). Slender needles (containing 2aq), v. sol. water, v. sl. sol. alcohol and ether. Not decomposed at  $150^\circ$ .  $\text{FeSO}_4$  gives a brownish-red colour. —  $\text{Ba}_2\text{A}''$ , 2½aq. —  $\text{Ba}_2\text{A}''$ , 2aq. —  $\text{Cu}_2\text{A}''$ , 2½aq. —  $\text{Ag}_2\text{A}''$ , 2aq.

**Pyridine penta-carboxylic acid  $\text{NC}_6\text{H}_4(\text{CO}_2\text{H})_5$**

Formed from potassium tri-methyl-pyridine dicarboxylate and  $\text{KMnO}_4$  (Hantzsch, A. 215, 62; Weber, A. 241, 15). Crystalline mass of minute needles (containing 2aq), extremely sol. water, v. sl. sol. ether. Acid to litmus and to taste. Loses 2aq at  $120^\circ$  and decomposes, without having melted, at  $220^\circ$ . The neutral alkaline salts are very soluble, but the acid alkaline salts are sl. sol. water. The acid does not combine with  $\text{HCl}$ . Distilled with lime it gives pyridine.  $\text{FeSO}_4$  gives a dark-red colour.

water, forming an acid solution (Gardner, *B. 23*, 1588).—Formate  $B'3CH_3O_2$ . (149°). Liquid, v. sol. water.—Propionate  $B'3C_2H_5O_2$ . (149°). Liquid.—Cupric oxalate compound  $B'_2CuC_2O_4$ : minute prisms (Seubert a. Rauter, *B. 25*, 2825).

**Methylo-chloride**  $B'MeCl$ . White needles (Ostermeyer, *B. 18*, 591). Converted by a hot aqueous solution of picric acid into  $B'MeOC_6H_3(NO_2)_3$ , aq., which crystallises in greenish-yellow explosive needles [34°].— $B'_2Me_2PtCl_6$ . [188°] (O.); [207°] (B.).— $B'MeAuCl_4$ . [253°].— $B'MeClHCl$ . [82°] (O.); [90°] (B.). Yellow plates.— $B'MeClHCl_2$ . [180°]. Unstable yellow crystals (Bally, *B. 21*, 1774).

**Methylo-perbromide**  $B'MeBr_3$ . [48°].

**Methylo-iodide**  $B'MeI$ . Converted at 290° into methyl-pyridine hydriodides. On heating with alcoholic potash at 45° it yields a brown resin, forming a deep-red solution in alcohol, turned bright-red by HCl, orange-red by acetic acid, and ruby-red by ammonia (O. de Coninck, *C. R.* 102, 1479). Chlorine forms  $B'MeICl_2$  [90°] (*v. supra*). Oxidised by alkaline  $K_2FeCy_6$  to oxy-methyl-pyridine or  $\nu$ -methyl-pyridone  $CH \leftarrow CH.CO > NMe$  (250°), a liquid miscible with water (Decker, *J. pr.* [2] 47, 28; cf. Pechmann, *B. 24*, 3144).

**Ethyl-iodide**  $B'EtI$ . Silvery tables (Anderson, *A. 94*, 364). At 300° it yields pyridine,  $NH_3$ , (a) and ( $\gamma$ )-ethyl-pyridine, and diethyl-pyridine (Ladenburg, *B. 16*, 2059; 18, 2961). Yields  $B'EtPtCl_6$ . Oxidised by alkaline  $K_2FeCy_6$  to  $CH \leftarrow CH.CO > NEt$  (250°).

**Ethylene-iodide**  $B'C_2H_4I_2$ . Prisms (Coppola, *G. 15*, 332). Ag<sub>2</sub>O yields a base  $C_2H_4NO$ . By heating pyridine with ethylene bromide and some alcohol at 100° there is found  $B'_2C_2H_4Br_2$ , which yields  $B'_2C_2H_4PtCl_6$  (Davidson, *A. 121*, 254).

**Benzyl-chloride**  $B'PhCH_2Cl$ . Reduced by sodium-amalgam to the unstable  $C_{10}H_{12}N_2$  (Hofmann, *B. 14*, 1503).—( $B'PhCH_2Cl$ ),  $PtCl_4$ .

**Nitro-benzyl-chlorides**  
 $B'O_2C_6H_4(NO_2)CH_2Cl$ . o [a. 76°], m [70°–100°], p [90°–100°]. These bodies are reduced by tin and HCl aq. to  $B'O_2C_6H_4(NH_2)CH_2Cl$ , which are split up by heat into pyridine hydrochloride and  $C_6H_5 \leftarrow \begin{smallmatrix} NH_2 \\ CH_2 \end{smallmatrix} Cl$  (Lellmann a. Pekrun, *A. 259*, 54).

**Phenacylo-bromide**  $B'BzCH_2Br$ . Prisms (Bamberger, *B. 20*, 3344).— $B'(BzCH_2)CrO_3$ .

**References.**—Bromo-, Chloro-, Oxy-amido-, and Oxy-pyridine.

**Dipyridine**  $C_{10}H_{10}N_2$  v. DIPYRIDYL DIHYDRIDE.

**Dipyridine**  $C_{10}H_{10}N_2$ . (275°). S.G.  $\approx$  1.124. Is probably a dipyridyl dihydride. Formed by heating nicotine with KOH and  $K_2FeCy_6$ , and also by heating the product of the action of S on nicotine at 150° with finely-divided copper (Cahours a. Etard, *Bl.* [2] 34, 452). Inactive liquid.— $B'HHgCl_2$ .— $B'_2H_2PtCl_6$  2aq.— $B'_2H_2FeCy_6$  2aq.: brownish-green tables.

(a)-PYRIDINE CARBOXYLIC ACID

$C_6H_5NO_2$ , i.e.  $CH:CH.CO_2H$ . **Picolinic acid**. [188°]. Formed by oxidation of (a)-methyl-pyridine with  $KMnO_4$  (Weidel, *B. 12*, 1994), and by oxidation of (a)-phenyl-pyridine (Skraup, *M.*

4, 477). Obtained also, together with its hydride, from comenamic acid by successive treatment with  $PCl_5$  and  $H_2SO_4$ , the resulting di-chloro-picolinic acid being reduced by heating for three days at 155° with HI dissolved in HOAc (Ost, *J. pr.* [2] 27, 285).

**Preparation.**—The three acids got by oxidation of crude methyl-pyridine from animal oil are converted into copper salts. Cupric pyridine (a)-carboxylate is extracted by hot water. The residue is treated with  $H_2S$ , and the difficultly-soluble ( $\gamma$ )-acid separated from the ( $\beta$ )-acid (Ost, *J. pr.* [2] 27, 286).

**Properties.**—Needles, v. sol. water and alcohol, almost insol. ether, benzene,  $CHCl_3$ , and  $CS_2$ . May be sublimed.  $FeSO_4$  gives a red colouration with picolinic acid and with all the carboxylic acids of pyridine that contain  $CO_2H$  in the (a)-position (Skraup, *M. 7*, 210). The absorption of the ultra-violet spectrum has been studied by Hartley (*C. J.* 41, 45).

**Reactions.**—1. Yields pyridine on distillation with lime or with alcoholic potash at 240°. The Cu salt on distillation gives pyridine and (a)-dipyridyl [70°] (Blau, *M. 10*, 375; *B. 21*, 1077).—2. Sodium-amalgam forms  $\delta$ -oxy-adipic acid (Weidel, *M. 11*, 522).—3. Fuming HI at 170° forms (a)-methyl-pyridine and piperidine (Seyferth, *J. pr.* [2] 34, 241).—4. Zinc-dust and HOAc reduce it to (a)-methyl-pyridine.

**Constitution.**—This may be deduced from its formation from ( $\beta$ )-naphthoquinoline *vid.* ( $\beta$ )-phenyl-pyridine carboxylic acid (Skraup a. C. benzl, *M. 4*, 436).

**Salts.**— $HA'HCl$ : unstable crystals.— $H_2A'_2H_2PtCl_6$  2aq.: orange-red crystals.— $NH_4A'$ : triclinic tables.— $KA'$ .— $BaA'_2$   $\frac{1}{2}$  aq.— $CaA'_2$  aq.— $MgA'_2$  2aq.

**Hexahydride**  $C_6H_{10}N.CO_2H$ . **Piperidine** (a)-carboxylic acid. The chief product of the action of HI at 160° on mono- or di-chloro-picolinic acid (Ost, *J. pr.* [2] 27, 287). Got also by reducing picolinic acid (Ladenburg, *B. 24*, 640). Syrup, v. sol. water. Salts.— $B'HCl$ . [264°]. Nodules.— $B'_2H_2PtCl_6$ . [184°] (L.).— $B'_2H_2PtCl_6$  2aq.— $B'MeCl$ . [191°]. Needles.

**Pyridine** ( $\beta$ )-carboxylic acid

$CH:CH.CO_2H$ . **Nicotinic acid**. [230°].  $CH: N.CO_2H$

**Formation.**—1. By oxidising nicotine with  $HNO_3$  (Weidel, *A. 165*, 330),  $CrO_3$  (Huber, *A. 141*, 271; *B. 3*, 849), or  $KMnO_4$  (Laiblin, *A. 196*, 129).—2. A product of oxidation of coal-tar bases (Weidel; Mohler, *B. 21*, 1009).—3. By heating quinolinic acid at 160° or with HCl at 180° (Ost, *J. pr.* [2] 27, 286; Lippmann a. Fleissner, *M. 8*, 315).—4. By oxidation of ( $\beta$ )-methyl-pyridine (Weidel, *B. 12*, 2004), ( $\beta$ )-ethyl-pyridine (Stoehr, *J. pr.* [2] 43, 155) or ( $\beta$ )-phenyl-pyridine (Skraup, *M. 4*, 453).—5. By saponification of its nitrile, which is got by distilling sodium-pyridine sulphate with  $KCy$  (Fischer, *B. 15*, 63).—6. By heating three of the pyridine dicarboxylic acids (Hoogewerff a. Van Dorp, *R. T. C. 1*, 1, 107; *A. 204*, 117; 207, 226; Weidel a. Herzig, *M. 1*, 16).—7. By heating berberonic acid at 215° (Fürth, *M. 2*, 420).—8. By the action of Zn and HCl aq. on chloro-nicotinic acid (Pechmann a. Welsh, *C. J.* 47, 145).

**Properties.**—Needles, s. sol. cold water, sol. alcohol, nearly insol. ether. May be sublimed.

**Reactions.**—1. Yields pyridine on distillation with lime.—2. Sodium-amalgam yields a mixture of  $\delta$ -oxy- $\alpha$ -methyl-glutaric acid and its lactone, which, on treatment with alcohol and HCl, yields a mixture of two ethers. One of these,  $C_8H_{11}ClO_4$ , is converted by sodium-amalgam into  $\alpha$ -methyl-glutaric acid, and the other,  $C_8H_{11}O_4$ , is also converted by successive treatment with  $PL_2$  and with Zn and dilute  $H_2SO_4$  into  $\alpha$ -methyl-glutaric acid (Weidel, *M.* 11, 502).—3. Bromine and water at  $120^\circ$  yield  $CO_2$ , pyridine, and bromoform.—4. The K salt heated with MeI at  $150^\circ$  forms  $C_8H_9NMe.CO_2Me$ , which on saponification yields  $C_8H_9NMe(OH).CO_2H$  [ $130^\circ$ ], converted at  $100^\circ$  into trigonellin  $C_8H_9NMe \begin{smallmatrix} \diagup CO \\ \diagdown O \end{smallmatrix}$  [ $218^\circ$ ], which occurs in the seeds of *Trigonella foenum graecum* (Jahns, *B.* 18, 2521; Hantzsch, *B.* 19, 81). This anhydride forms the salts  $C_8H_9NO.HCl$ ,  $B'H.PtCl_6$  aq,  $B'HAuCl_4$  [ $198^\circ$ ], and  $B'3HAnCl_4$  [ $186^\circ$ ].

**Constitution.**—This may be deduced from its formation from (a)-naphthaquinoline *via* (a)-phenyl-pyridine carboxylic acid.

**Salts.**— $HA'HCl$ . Colourless prisms.— $H_2A'H_2PtCl_6$  2aq.— $B'H_2AuCl_4$ .— $B'HNO_3$  aq.— $NH_4A'$ : needles.— $KA'$ .— $MgA'_2$ : needles.— $CaA'_2$  6aq: monoclinic crystals;  $a:b:c = 1.537:1:0.629$ ;  $\beta = 62^\circ 50'$ .— $Cu(OH)A'$  (De Coninck, *Bl.* [2] 42, 100).— $AgA'$ : needles (from hot water).

**Nitrile**  $C_8H_9N.Cy$ . [ $49^\circ$ ]. Formed by distilling sodium pyridine sulphate with KCy (Fischer, *B.* 15, 63). Needles or prisms, sol. water.— $B'HCl$ .— $B'H_2PtCl_6$ : yellow soluble needles. Tables (by sublimation). Converted by means of hydroxylamine into the amidoxim  $C_8H_9N.C(NH_2).NOH$  [ $128^\circ$ ], which yields an acetyl derivative [ $143^\circ$ ] and a benzoyl derivative [ $190^\circ$ ], and is converted by phenyl cyanate into  $C_8H_9N.C(NOH).NH.CO.NHPh$  [ $167^\circ$ ], by phenyl thiocarbimide into  $C_8H_9N.C \begin{smallmatrix} \diagup N \\ \diagdown S \end{smallmatrix} \gg C.NHPh$  [ $241^\circ$ ], and by succinic anhydride at  $100^\circ$  into  $C_8H_9N \begin{smallmatrix} \diagup N.O \\ \diagdown N \end{smallmatrix} \gg C.CH_2.CH_2.CO_2H$  [ $178^\circ$ ]. The acetyl and benzoyl derivatives are converted by heating into  $C_8H_9N \begin{smallmatrix} \diagup N.O \\ \diagdown N \end{smallmatrix} \gg CMe$  [ $109^\circ$ ] and  $C_8H_9N \begin{smallmatrix} \diagup N.O \\ \diagdown N \end{smallmatrix} \gg CPh$  [ $139^\circ$ ] respectively (Michaëlis, *B.* 24, 3439).

**Hexahydrate**  $C_8H_9N.CO_2H$ . *Nipecotinic acid*. [ $250^\circ$ ]. Got by reducing nicotinic acid in alcoholic solution by Na (Ladenburg, *B.* 25, 2768). Crystals, v. e. sol. water, insol. alcohol and ether.— $HA'HCl$ . [ $240^\circ$ ].— $H_2A'H_2PtCl_6$ . [ $218^\circ$  cor.].— $HA'HCl$ . [ $197^\circ$  cor.].— $HA'HCl.HgCl_2$ . [ $231^\circ$ ].— $MeA'HCl$  [ $208^\circ$ ].— $MeA'H_2PtCl_6$ .—Nitrosamine  $C_8H_9N_2O$ . [ $112^\circ$ ].

**Pyridine ( $\gamma$ )-carboxylic acid**

$N \begin{smallmatrix} \diagup CH.CH \\ \diagdown CH:CH \end{smallmatrix} \gg C.CO_2H$ . *Isonicotinic acid*. [ $305^\circ$ ] (*S.*); [ $306^\circ$ ] (*B. a. H.*); [ $309.5^\circ$ ] (*W. a. H.*).

**Formation.**—1. By heating pyridine  $\delta$ -tricarboxylic acid (Skraup, *B.* 12, 2331) and three of the pyridine di-carboxylic acids (Hoogewerff a. Van Dorp, *A.* 204, 112; Weidel a. Herzig, *M.* 1, 28; Böttinger, *B.* 11, 68).—2. By the action of  $KMnO_4$  on ( $\gamma$ )-methyl-pyridine (Behrmann a. Volz, *IV.*

Hofmann, *B.* 17, 2696; Ladenburg, *B.* 21, 287).—3. By heating di-chloro-pyridine carboxylic acid [ $210^\circ$ ] with HI (*B. a. H.*).

**Properties.**—Needles, sl. sol. cold water, insol. alcohol. Yields pyridine on distilling with lime and  $\delta$ -oxy-ethyl-succinic acid on reduction with sodium-amalgam (Weidel, *M.* 11, 517).

**Salts.**— $NH_4A'$ : needles.— $CaA'_2$  4aq: silky needles, m. sol. water.— $HA'HCl$ : monoclinic prisms.— $H_2A'H_2PtCl_6$  2aq: monoclinic crystals.

**Hexahydrate**  $C_8H_9N.CO_2H$ . Got by reducing the acid in alcoholic solution by Na (Ladenburg, *B.* 25, 2773). Branching groups of needles, v. e. sol. water, insol. alcohol. Blackens at  $300^\circ$ , but is not melted at  $320^\circ$ .— $HA'HCl$ . [ $228^\circ$ ]. Trimetric crystals;  $a:b:c = .922:1:0.979$ .— $H_2A'H_2PtCl_6$ . [ $239^\circ$ ].—Aurochloride: [ $197^\circ$ ]. Nitrosamine  $C_8H_9N_2O$ . [ $101^\circ$ ].

**Pyridine (aa)-dicarboxylic acid**

$CH \begin{smallmatrix} \diagup CH.C(CO_2H) \\ \diagdown CH:C(CO_2H) \end{smallmatrix} \gg N$ . *Dipicolinic acid*. [ $220^\circ$ ]

(*L. a. R.*; *S.*); [ $237^\circ$ ] (*E.*); [ $236^\circ$  cor.] (*Collie, C. J.* 59, 179). Formed by oxidation of (aa)-dimethyl-pyridine [ $145^\circ$ ] (derived from acetoacetic ether or from coal-tar) by  $KMnO_4$  (Epstein, *A.* 231, 26; Ladenburg a. Roth, *B.* 18, 52; 19, 790; 20, 130; *A.* 247, 32; Lange a. Rosenberg, *B.* 20, 132; cf. Dewar, *C. N.* 23, 18). Got also by oxidation of (a)-methyl-(a)-ethyl-pyridine by dilute (2 p.c.)  $KMnO_4$  (Schultz, *B.* 20, 2724).

**Properties.**—Hair-like needles (containing  $1\frac{1}{2}$  aq) or anhydrous scales; sl. sol. cold alcohol, water, and ether. On heating at  $245^\circ$  in a current of H it yields pyridine and pyridine (a)-carboxylic acid.  $PCl_5$  forms a chloride [ $61^\circ$ ] ( $284^\circ$ ).  $FeSO_4$  gives a reddish-yellow colour.

**Salts.**— $CaA''$  2aq: minute prisms.— $CaA''$  2aq: dark-blue prisms.

**Pyridine (ab)-dicarboxylic acid**

$C(CO_2H).C(CO_2H) \begin{smallmatrix} \diagup CH \\ \diagdown CH=CH \end{smallmatrix} \gg N$ . *Quinolinic acid*. [ $231^\circ$ ].

*S.*  $\cdot 55$  at  $6.5^\circ$ . Formed by the oxidising action of  $KMnO_4$  on quinoline (Hoogewerff a. van Dorp, *B.* 12, 747; *R. T. C.* 1, 107; *A.* 204, 117), on cinchonine (*H. a. D.*), on o- and p-methyl-quinoline (Skraup, *M.* 2, 157), on o-oxy-quinoline, on quinoline o-sulphonic acid (O. Fischer a. Renout, *B.* 17, 755), and on (a)-oxy-quinoline carboxylic acid (La Coste a. Valeur, *B.* 20, 103).

**Properties.**—Monoclinic needles,  $a:b:c = .542:1:0.607$ ;  $\beta = 64^\circ 54'$ ; sl. sol. water and alcohol, insol. ether. Begins to decompose at  $140^\circ$ , and forms nicotinic acid. Yields pyridine when distilled with lime. Reduced by sodium-amalgam to the  $\delta$ -lactone of butane  $\alpha\beta\gamma$ -tricarboxylic acid  $CH_2.CH_2.CH.CO_2H$  (Perlmutter, *M.* 13, 840).

**Salts.**— $KHA''$  2aq: triclinic plates (Lippmann a. Fleisener, *M.* 8, 311).— $KA''$  2aq.— $BaA''$  aq.— $AgA''$ : crystalline.— $AgHA''$  aq.

**Anhydride**  $C_8H_9N \begin{smallmatrix} \diagup CO \\ \diagdown CO \end{smallmatrix} \gg O$ . [ $185^\circ$ ]. Got

from the acid and  $Ac_2O$  (Bernthsen a. Mettengang, *B.* 20, 1208). Prism. Converted by benzene and  $AlCl_3$  into  $C_8H_9BzN.CO_2H$  [ $147^\circ$ ], converted by heat into the ketone  $C_8H_9BzN$  ( $307^\circ$  uncor.), which yields a crystalline phenylhydrazide [ $143.5^\circ$ ].

**Pyridine ( $\alpha\gamma$ )-dicarboxylic acid**

$CO_2H.O \begin{smallmatrix} \diagup CH:C(CO_2H) \\ \diagdown CH=CH \end{smallmatrix} \gg N$ . *Lutidinic acid*.

[240°] (V.); [235°] (B.; L. a. R.). Formed by the oxidising action of  $\text{KMnO}_4$  on ( $\alpha\gamma$ )-dimethyl-pyridine (Ramsay, *P. M.* [5] 4, 241; 6, 19; Weidel a. Herzig, *M.* 1, 20; Ladenburg a. Roth, *B.* 18, 915; *A.* 247, 87), on ( $\alpha$ )-methyl-( $\gamma$ )-ethyl-pyridine (Schultz, *B.* 20, 2726), on diethyl-pyridine, on ( $\alpha\alpha$ )-di-methyl-dipyridyl (Heuser a. Stoehr, *J. pr.* [2] 44, 409), and on the methyl-pyridine carboxylic acid obtained from uvitonic acid (Böttlinger, *B.* 14, 68; 17, 93; Voigt, *A.* 228, 54).

**Properties.**—Needles (containing aq), m. sol. cold water, sol. alcohol, insol. ether. Gives a blood-red colour with  $\text{FeSO}_4$ . Yields pyridine on distillation with lime. Converted by heat into  $\text{CO}_2$  and isonicotinic acid.  $\text{PCl}_5$  yields a chloride [203°].

**Salts.**— $\text{KHA}''$  1/2 aq. Crystals.  $(\text{NH}_4)_2\text{A}''$ .  $(\text{NH}_4)\text{HA}''$  aq: hygroscopic needles.  $\text{CaA}''$  3 aq.  $\text{CaA}''$  aq.  $\text{CaA}''$  1/2 aq.  $\text{CaH}_2\text{A}''$  2 aq.  $\text{BaA}''$  aq.  $\text{BaA}''$  1/2 aq. (B.).  $\text{BaA}''$  3 aq.  $\text{CdA}''$  4 aq (Waage, *M.* 4, 727).  $\text{MgA}''$  5 aq.  $\text{CuA}''$  3 aq.  $\text{CuA}''$  4 aq (B.).  $\text{Ag}_2\text{A}''$  2 aq: white pp.

**Pyridine ( $\alpha\beta$ )-dicarboxylic acid**

$\text{CH} \begin{smallmatrix} \text{CH}:\text{C}(\text{CO}_2\text{H}) \\ \text{C}(\text{CO}_2\text{H})\text{CH} \end{smallmatrix} \text{N}$ . *Isocinchomeronic acid.* [236°].

**Formation.**—1. By oxidation of lutidine ( $150^\circ$ – $170^\circ$ ) with  $\text{KMnO}_4$  (Ramsay, *P. M.* [5] 4, 246; Weidel a. Herzig, *M.* 1, 1; Lange a. Rosenberg, *B.* 20, 135).—2. By oxidising ( $\beta'$ )-methyl-( $\alpha$ )-ethyl-pyridine (Ladenburg, *A.* 247, 44).—3. By oxidation of quinine (Ramsay a. Dobbie, *C. J.* 33, 102; *B.* 11, 324).—4. By heating the dihydride of potassium pyridine tricarboxylate (Weiss, *B.* 19, 1311).—5. By the action of alkaline  $\text{KMnO}_4$  on cyclothaustic acid and on pyridanthrillic acid (Weidel a. Strache, *M.* 7, 290).—6. By oxidising ( $\beta$ )-ethyl-( $\alpha$ )-stilbazole (Plath, *B.* 22, 1062).

**Properties.**—Small prisms (containing aq), almost insol. cold water, alcohol, and benzene, sol. hot  $\text{HClAq}$ . On heating with  $\text{HOAc}$  at  $220^\circ$  it is split up into  $\text{CO}_2$  and nicotinic acid [230°]. On heating with lime it gives pyridine.  $\text{PCl}_5$  yields a chloride [61°] converted by  $\text{NH}_3$  into an amide [297°].  $\text{FeSO}_4$  gives a reddish colour.

**Salts.**— $(\text{NH}_4)\text{HA}''$  aq. [253°]. Triolinio prisms, sl. sol. cold water.  $(\text{NH}_4)_2\text{A}''$ .  $\text{KHA}''$  1/2 aq: needles.  $\text{KA}''$  aq.  $\text{CaA}''$  2 aq.  $\text{Ca}(\text{HA}'')_2$  3 aq.  $\text{MgA}''$  5 aq.  $\text{CuA}''$  aq.  $\text{Ag}_2\text{A}''$ . *Methyl ether MeA''*. [117°5'] (R.).

**Pyridine ( $\beta\delta'$ )-dicarboxylic acid**

$\text{CH} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H})\text{CH} \\ \text{C}(\text{CO}_2\text{H})\text{CH} \end{smallmatrix} \text{N}$ . *Dinicotinic acid.* [322°]. Formed by heating pyridine (2,3,5)-tri-carboxylic acid and pyridine (2,3,5,6)-tetra-carboxylic acid (Riedel, *B.* 16, 1613; Hantzsch a. Weiss, *B.* 19, 286; Weber, *A.* 241, 12). Formed also by heating di-chloro-pyridine di-carboxylic acid with conc.  $\text{HIAq}$  at  $180^\circ$  (Guthzeit, *A.* 262, 130).

**Properties.**—Small prisms (from  $\text{HOAc}$ ), split up by heat into  $\text{CO}_2$  and nicotinic acid.

**Salts.**— $\text{PbA}''$  2 aq.  $\text{Ag}_2\text{A}''$  aq.  $\text{Ag}_2\text{A}''$  1 1/2 aq.  $\text{HA}''\text{HCl}$  2 aq: needles, decomposed by water.  $\text{H}_2\text{A}''\text{H}_2\text{PtCl}_6$ : orange-red needles.

**Pyridine ( $\beta\gamma$ )-dicarboxylic acid**

$\text{CO}_2\text{H.C} \begin{smallmatrix} \text{C}(\text{CO}_2\text{H})\text{CH} \\ \text{CH} \end{smallmatrix} \text{N}$ . *Cinchomeronic acid.* [259°].

**Formation.**—1. By oxidation of cinchonine or cinchonidine by  $\text{HNO}_3$  of S.G. 1.4 (Weidel, *A.* 173, 76).—2. By oxidation of quinine by  $\text{HNO}_3$ , the yield being 28 p.c. (Weidel a. Schmidt, *B.* 12, 1146).—3. By heating apophyllenic acid with conc.  $\text{HClAq}$  at  $240^\circ$  (Von Gerichten, *B.* 13, 1635).—4. By heating pyridine tricarboxylic acid (formed from cinchonic acid) at  $190^\circ$  (Hoogewerff a. van Dorp, *B.* 13, 61; Skraup, *M.* 1, 184; Weidel a. Brix, *M.* 3, 604).—5. By the action of  $\text{KMnO}_4$  on methyl-pyridine carboxylic acid and on isoquinoline (Hoogewerff a. van Dorp, *R. T. C.* 2, 23; 4, 285).—6. By heating pyridine pentacarboxylic acid (Weber, *A.* 241, 16).—7. By oxidation of methyl-nicotinic acid, derived from ( $\beta$ )-collidine (Oechsner de Coninck, *Bl.* [2] 43, 106).—8. By boiling berberonic acid with  $\text{HOAc}$  (2 pts.) and  $\text{Ac}_2\text{O}$  (1 pt.) for six hours (Mayer, *M.* 13, 344; cf. Fürth, *M.* 2, 426).

**Properties.**—Prisms (from  $\text{HClAq}$ ), v. sl. sol. water and ether, sl. sol. alcohol. Yields isonicotinic and some nicotinic acid on heating (Hoogewerff a. van Dorp, *A.* 207, 217). Gives pyridine on distillation with lime. Sodium-amalgam yields  $\text{NH}_3$  and cinchonic acid  $\text{C}_8\text{H}_9\text{O}_4$ , i.e.  $\text{CO}_2\text{H.C} \begin{smallmatrix} \text{CH}_2\text{CO} \\ \text{CH.CH}_2 \end{smallmatrix} \text{O}$  (Weidel a. Hoff, *M.*

13, 578). Cinchonic acid [169°] forms monoclinic crystals, v. sol. hot water and alcohol, and yields  $\text{BaC}_2\text{H}_3\text{O}_4$  3 aq,  $\text{Ba}_2(\text{C}_2\text{H}_3\text{O}_4)_2$  3 aq,  $\text{CaA}''$  2 aq,  $\text{Ca}(\text{C}_2\text{H}_3\text{O}_4)_2$  (dried at  $190^\circ$ ), and oily  $\text{Et}_2\text{A}''$ , whence  $\text{PCl}_5$ , followed by alcohol, yields  $\text{CO}_2\text{Et.C}(\text{CH}_2\text{Cl})\text{CH}(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{Et}$ , which is a heavy oil. Cinchonic acid is reduced by  $\text{HI}$  to butane tricarboxylic acid  $\text{C}_4\text{H}_9\text{O}_6$  [184°], whence  $\text{Ca}_2\text{A}''$  8 aq, accompanied by an isomeric butane tricarboxylic acid [133°].  $\text{FeSO}_4$  gives no colour.

**Salts.**— $\text{Na}_2\text{A}''$  2 aq: tables.  $\text{NaHA}''$ .  $\text{BaA}''$  1 1/2 aq: needles, sl. sol. water.  $\text{CaA}''$  3/4 aq: prisms.  $\text{CaA}''$  3 aq.  $\text{CuA}''$  3/4 aq: small blue crystals.  $\text{Ag}_2\text{A}''$ : white pp.  $\text{AgHA}''$ .  $\text{HA}''\text{HCl}$ : monoclinic prisms, decomposed by water.  $\text{H}_2\text{A}''\text{H}_2\text{PtCl}_6$ : golden prisms.

**Anhydride** ( $\text{C}_8\text{H}_5\text{N}_2\text{O}_3$ ) [77°]. Formed by boiling the acid with  $\text{Ac}_2\text{O}$  (Goldschmiedt a. Strache, *M.* 10, 156). Plates. May be sublimed. Converted by  $\text{NH}_3$  gas into  $\text{C}_8\text{H}_5\text{N}(\text{CO}_2\text{NH}_2)\text{CONH}_2$  [229°], which is converted by heat into a yellow powder [130°], and which yields the amic acid  $\text{C}_8\text{H}_5\text{N}(\text{CO}_2\text{H})\text{CONH}_2$  [237°], crystallising in needles.

**Mono-ethyl ether HEtA''**. [133°]. Formed from the anhydride and  $\text{EtOH}$ . Plates (from benzene).  $\text{AgEtA}''$ : long needles.

**Mono-methyl ether HMeA''**. [154°].

**Anhydride of the Methyl-hydroxide**  $\text{C}_8\text{H}_7\text{NO}$ , i.e.  $\text{C}_8\text{H}_7\text{NMe}(\text{CO}_2\text{H}) \begin{smallmatrix} \text{CO} \\ \text{O} \end{smallmatrix}$ . **Apophyllenic acid** [242°]. Formed by oxidation of cotarnine by  $\text{HNO}_3$  (Wöhler, *A.* 50, 24; Anderson, *Tr. E.* 23, 347; *C. J.* 5, 257; Gerichten, *B.* 13, 1635). Formed also by heating cinchomeronic acid with  $\text{MeI}$  and  $\text{MeOH}$  at  $100^\circ$  (Roser, *A.* 234, 116). Needles (anhydrous) or octahedra (containing aq), sol. hot water, insol. alcohol and ether.  $\text{HClAq}$  at  $250^\circ$  decomposes it, forming cinchomeronic acid and  $\text{MeCl}$ .  $\text{BaA}''$ .  $\text{AgA}''$ .  $\text{Ag}_2\text{A}''(\text{NO}_3)$ .  $\text{H}_2\text{A}''\text{H}_2\text{PtCl}_6$  aq.

**Bromo-apophyllenic acid**

$C_6H_5BrNO_2$ , 2aq. [205°]. Formed by oxidation of bromo-tarconine. Yields  $BaA''$ , 3aq and  $H_2A''$ ,  $H_2PtCl_4$  (Gerichten, A. 210, 91).

**Pyridine ( $\alpha\alpha'\beta$ )-tricarboxylic acid**

$CH \begin{smallmatrix} \diagup C(CO_2H) \\ \diagdown C(CO_2H) \end{smallmatrix} \begin{smallmatrix} \diagup C(CO_2H) \\ \diagdown C(CO_2H) \end{smallmatrix} N$ . Formed by oxidising di-methyl-nicotinic acid with  $KMnO_4$  (Weiss, B. 19, 1309). Crystallises from alcohol in plates (containing 2aq), v. e. sol. water. Decomposes at 160° into  $CO_2$  and isocinchomeronic acid.  $FeSO_4$  colours its neutral solution red. —  $KH_2A''$ , 5aq: needles. —  $Ca_2A''$ , 4aq. —  $Pb_2A''$ , 5aq.

**Pyridine ( $\alpha\alpha'\gamma$ )-tricarboxylic acid**

$CO_2H.C \begin{smallmatrix} \diagup CH.C(CO_2H) \\ \diagdown CH.C(CO_2H) \end{smallmatrix} N$ . *Trimesitic acid*. *Carbolutidinic acid*. [244°]. Formed by oxidation of uvitonic acid (Böttiger, B. 13, 2048; 14, 69), and by oxidation of the tri-methyl-pyridine obtained from acetoacetic ether and aldehyde-ammonia (Voigt, A. 228, 81). Tables or spheroidal groups of needles (containing 2aq), sol. hot water, sl. sol. alcohol and ether. Yields isonicotinic acid on sublimation.  $FeSO_4$  gives a violet-red colour.

Salts. —  $K_2A''$ , 5aq: needles. —  $Ca_2A''$ , 4aq. —  $Ba_2A''$ , 6aq. —  $BaH_2A''$ , 4aq. —  $Mg_2A''$ , 12aq. —  $Cu_2A''$ , 12aq. —  $Ag_2A''$ , 11aq.

**Ethyl ether  $Et_2A''$ . [127-5°].****Amide. [above 280°].****Pyridine ( $\alpha\beta\beta'$ )-tri-carboxylic acid**

$CH \begin{smallmatrix} \diagup C(CO_2H).C(CO_2H) \\ \diagdown C(CO_2H) \end{smallmatrix} \begin{smallmatrix} \diagup C(CO_2H) \\ \diagdown CH \end{smallmatrix} N$ . *Carbodinitic acid*. [323°]. Formed by oxidation of quino-line (Py. 2)-carboxylic acid (Riedel, B. 16, 1615), of methyl-pyridine ( $\beta\beta'$ )-dicarboxylic acid (Weber, A. 241, 11), and of the parvolino got by heating propionic aldehyde-ammonia with propionic aldehyde at 200° (Dürkop, B. 21, 832, 2707; 23, 689). Spherical aggregates (containing 1½aq), v. sol. hot water. At 155° it is split up into  $CO_2$  and dinicotinic acid. —  $Ba_2A''$ , 5aq. —  $Ag_2H_2A''$ , 1½aq: rosettes of plates.

**Pyridine ( $\alpha\beta\gamma$ )-tri-carboxylic acid**

$CO_2H.C \begin{smallmatrix} \diagup C(CO_2H).C(CO_2H) \\ \diagdown CH \end{smallmatrix} N$ . [250°] (H. a. D.; S.); [257°] (D. a. R.). S. 1-2 at 15°.

**Formation.**—1. By the action of  $KMnO_4$  on quinine, cinchonine, cinchonidine, quinoidine, and cinchonic acid (Dobbie a. Ramsay, C. J. 35, 189; Hoogewerff a. van Dorp, B. 12, 158; 13, 152; A. 204, 84; Skraup, A. 201, 312; Strache, M. 10, 642).—2. By oxidation of cinchonine by  $HNO_3$  (Weidel, A. 173, 101; B. 12, 415).—3. By oxidation of methyl-pyridine ( $\alpha\beta$ )-dicarboxylic acid (Hoogewerff a. van Dorp, R. T. C. 2, 18), of di-methyl-pyridine dicarboxylic acid (Michael, B. 18, 2027), of ( $\alpha$ )-oxy-cinchonic acid (Weidel a. Cobenzl, M. 1, 865).—4. By oxidation of papaverine (Goldschmidt, M. 6, 397). Trimetric plates (containing 1½aq), v. sol. hot water, in. sol. alcohol, nearly insol. ether. Blackens at 200°.  $FeSO_4$  gives a reddish colour.  $H_2S$  forms a red amorphous body (D. a. R.). Decomposed by long heating at 180°, or by boiling with  $HOAc$  into  $CO_2$  and cinchomeronic acid. Yields pyridine on distilling with lime.  $MeI$  and  $MeOH$  at 100° form  $CO_2$  and apophyllenic acid. Sodium-amalgam gives  $NH_3$  and cinchonic acid.  $PCl_5$  forms a chloride (206° at 40 mm.).

Salts. —  $K_2A''$ , 3aq. —  $Ba_2A''$ , 16aq. —

$Ba_2A''$ , 12aq. —  $Ca_2A''$ , 14aq. —  $Ca_2A''$ , 13aq. —  $CaH_2A''$ , 2½aq. —  $Cu_2A''$ , 9aq: light-blue pp. —  $CuH_2A''$ , 3½aq: hexagonal prisms. —  $CuH_2A''$ , 2aq. —  $Cd_2A''$ , 6aq. —  $Ag_2H_2A''$ , 2aq. —  $Ag_2A''$ , 2aq: amorphous pp. —  $Ag_2H_2A''$ , 2½aq. —  $H_2A''HCl$ : crystalline powder (Roser, A. 234, 125).

**Pyridine ( $\alpha\beta'\gamma$ )-tricarboxylic acid**

$CO_2H.C \begin{smallmatrix} \diagup CH.C(CO_2H) \\ \diagdown C(CO_2H).CH \end{smallmatrix} N$ . *Berberonic acid*. [243°]. Formed by oxidising berberine with nitric acid (Weidel, B. 12, 410; Fürth, M. 2, 416). Trichinic prisms (containing 2aq), sol. hot water, v. sl. sol. hot alcohol, insol. ether. Yields pyridine on distillation with lime.  $FeSO_4$  gives a red colour. At 215° it is split up into  $CO_2$  and nicotinic acid; above 243° it yields isonicotinic acid.

Salts. —  $K_2A''$ , 4½aq. —  $K_2H_2A''$ , 3aq. —  $KH_2A''$ , 1½aq. —  $Ca_2A''$ , 8aq. —  $Cd_2A''$ , 4aq. —  $Ag_2A''$ : white pp., insol. water.

**Pyridine ( $\beta\beta'\gamma$ )-tricarboxylic acid**

$CO_2H.C \begin{smallmatrix} \diagup C(CO_2H).CH \\ \diagdown C(CO_2H).CH \end{smallmatrix} N$ . ( $\beta$ ). *Carbocinchomeronic acid*. [261°]. Formed, by heating dipotassium pyridine pentacarboxylate at 220° (Weber, A. 241, 17). Plates (containing 3aq), v. sol. hot water. Yields cinchomeronic acid when heated. Gives no colour with  $FeSO_4$ . —  $Cu_2H_2A''$ , 2½aq. —  $Ag_2A''$ , 2aq: crystalline pp.

**Pyridine ( $\alpha\beta\beta'\gamma$ )-tetra-carboxylic acid**

$C_6H_4NO_2$ , i.e.  $CO_2H.C \begin{smallmatrix} \diagup C(CO_2H).C(CO_2H) \\ \diagdown C(CO_2H).CH \end{smallmatrix} N$ . Formed by oxidising ( $\alpha\gamma$ )-di-methyl-pyridine ( $\beta\beta'$ )-dicarboxylic acid (Weber, A. 241, 23). Prisms (containing 2aq or 3aq). At 120° it loses  $CO_2$ , forming ( $\beta$ )-carbocinchomeronic acid.  $FeSO_4$  gives a dark-red colour. —  $Ba_2A''$ , 4aq. —  $Ag_2H_2A''$ , 2aq: crystalline.

**Pyridine ( $\alpha\alpha'\beta\beta'$ )-tetracarboxylic acid**

$CH \begin{smallmatrix} \diagup C(CO_2H).C(CO_2H) \\ \diagdown C(CO_2H).C(CO_2H) \end{smallmatrix} N$ . Formed by oxidising di-methyl-pyridine dicarboxylic acid (Hantzsch, B. 19, 286; Weber, A. 241, 4). Needles (containing 2aq), v. sol. water. Decomposes at 150° into  $CO_2$  and dinicotinic acid. —  $CaH_2A''$ , 2aq: needles, v. sol. water. —  $Cu_2A''$ , 5aq. —  $Ag_2A''$ , 2aq: bulky pp.

**Pyridine ( $\alpha\alpha'\beta'\gamma$ )-tetra-carboxylic acid**

$CO_2H.C \begin{smallmatrix} \diagup CH \end{smallmatrix} \begin{smallmatrix} \diagup C(CO_2H) \\ \diagdown C(CO_2H).C(CO_2H) \end{smallmatrix} N$ . Formed by oxidation of tri-methyl-pyridine carboxylic acid and of di-methyl-pyridine di-carboxylic acid (Michael, A. 225, 142). Formed also by oxidation of flavonol by alkaline  $KMnO_4$  (Fischer a. Täuber, B. 17, 2927). Slender needles (containing 2aq), v. sol. water, v. sl. sol. alcohol and ether. Not decomposed at 150°.  $FeSO_4$  gives a brownish-red colour. —  $Ba_2A''$ , 2½aq. —  $Ba_2A''$ , 5aq. —  $Cu_2A''$ , 2½aq. —  $Ag_2A''$ , 2aq.

**Pyridine penta-carboxylic acid  $NC_5(CO_2H)_5$ .**

Formed from potassium tri-methyl-pyridine dicarboxylate and  $KMnO_4$  (Hantzsch, A. 215, 62; Weber, A. 241, 15). Crystalline mass of minute needles (containing 2aq), extremely sol. water, v. sl. sol. ether. Acid to litmus and to taste. Loses 2aq at 120° and decomposes, without having melted, at 220°. The neutral alkaline salts are very soluble, but the acid alkaline salts are sl. sol. water. The acid does not combine with  $HCl$ . Distilled with lime it gives pyridine.  $FeSO_4$  gives a dark-red colour.

**Salts.**— $\text{KH}_2\text{A}^+$  2 or 3 aq. When heated swells up like Pharaoh's serpent.— $\text{K}_2\text{H}_2\text{A}^+$  8½ aq.— $\text{K}_2\text{A}^+$ .— $\text{Ba}_2\text{A}^+$ , 11 aq.— $\text{Ca}_2\text{A}^+$ , 12 aq.— $\text{CaH}_2\text{A}^+$  ¾ aq.— $\text{Mg}_2\text{A}^+$ , 12 aq.— $\text{Ca}_2(\text{NH}_4)\text{A}^+$  5 aq.— $\text{Ag}_2\text{HA}^+$  2 aq.

Double salt with oxalic acid  
 $\text{KH}_2\text{A}^+\text{KHC}_2\text{O}_4$  5 aq.

**References.**—Bromo- and Oxy-PYRIDINE CARBOXYLIC ACID.

**PYRIDINE TETRAHYDRIDE**  $\text{C}_5\text{H}_7\text{N}$  i.e.  $\text{CH}_2\langle\text{CH}:\text{CH}\rangle\text{NH}$ . *Piperidine*. Formed by heating amido-valeric aldehyde with solid KOH (Wolfenstein, *B.* 25, 2782).— $\text{B}^+\text{HAuCl}_4$ . [141°].— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{HCl}$ . [230°].— $\text{B}^+\text{HBr}$ . [178°].

**Pyridine hexahydride** v. *PIPERIDINE*.

**PYRIDINE (β)-SULPHONIC ACID**

$\text{C}_5\text{H}_7\text{N}\cdot\text{SO}_3\text{H}$ . Formed by heating pyridine (1 pt.) with  $\text{H}_2\text{SO}_4$  (3 pts.) at 320° (O. Fischer, *B.* 15, 62; 16, 1183). Small needles or plates, sol. water, sl. sol. alcohol, insol. ether. Br added to its boiling aqueous solution forms dibromopyridine. Potash-fusion gives oxy-pyridine [123°]. On distillation with  $\text{KCy}$  it yields the nitrile of nicotinic acid. The K salt, heated with MeI at 150° forms crystalline  $\text{C}_5\text{H}_7\text{NMe}\langle\text{SO}_2$  (Hantzsch, *B.* 19, 86).— $\text{BaA}^+$  4 aq.: needles.

**Pyridine sulphonic acid?**  $\text{C}_5\text{H}_7\text{N}\cdot\text{SO}_3$ . [155°]. Formed from pyridine and  $\text{ClSO}_3\text{H}$  (Wagner, *B.* 19, 1157). Crystalline, decomposed by water into pyridine and  $\text{H}_2\text{SO}_4$ .

**Pyridine disulphonic acid**  $\text{C}_5\text{H}_7\text{N}(\text{SO}_3\text{H})_2$ . Formed by heating piperidine (1 pt.) with  $\text{H}_2\text{SO}_4$  (10 pts.) (Königs, *B.* 16, 735; 17, 592). Needles (from  $\text{HOAc}$ ), v. sol. water, nearly insol. alcohol and ether.  $\text{PCl}_5$  at 200° forms tri-chloropyridine [48°].— $\text{Na}_2\text{A}^+$  4 aq.— $\text{K}_2\text{A}^+$  3 aq.— $\text{PbA}^+$  4½ aq.

**PYRIDONE** v. *OXY-PYRIDINE*.

(αα)-**DIPYRIDYL**  $\text{C}_{10}\text{H}_8\text{N}_2$  i.e.  $\text{C}_5\text{H}_7\text{N}\cdot\text{C}_5\text{H}_7\text{N}$ . [70°]. (272-5°). V.D. 5.6. Formed by distilling cupric picolinate (Blau, *B.* 21, 1077; *M.* 10, 875). Crystals (from water), m. sol. water, v. sol. alcohol. Not hygroscopic. Strong base.  $\text{FeSO}_4$  colours its aqueous solution red. Oxidised by  $\text{KMnO}_4$  to picolinic acid.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{HFeCy}_4$ .— $\text{B}^+\text{C}_6\text{H}_5\text{N}_3\text{O}_7$ . [155-5°]. Needles.

**Hexahydride**. Formed by reducing the base with zinc and  $\text{HClAq}$ . Alkaline oil.

**Dodecahydride**  $\text{C}_{10}\text{H}_{12}\text{N}_2$ . *Dipiperidyl*. (259° cor.). Formed by reducing the base, dissolved in isoamyl alcohol, by Na. Powerful base. Very deliquescent. Not poisonous. Forms with  $\text{CS}_2$  a compound [93°], and yields a nitrosamine [159°].— $\text{B}^+\text{H}_2\text{PtCl}_6$  2½ aq.

(ββ)-**Dipyriddy**  $\text{C}_{10}\text{H}_8\text{N}_2$ . [68°]. (287°) (L. a. O.); (292° at 736 mm.) (S. a. V.). Formed by distilling its dicarboxylic acid with KOH (Skrap a. Vortmann, *M.* 4, 591), and by the dry distillation of pyridine disulphonic acid (Leone a. Oliveri, *G.* 15, 276). Extremely deliquescent needles, miscible with water and alcohol, sl. sol. ether. Yields nicotinic acid on oxidation.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{C}_6\text{H}_5\text{N}_3\text{O}_7$ . [232°].

**Hexahydride**  $\text{C}_{10}\text{H}_{12}\text{N}_2$ . *Nicotidine*. (288°). Got by warming the base with tin and conc.  $\text{HClAq}$ . Poisonous oil, v. e. sol. water and alcohol, m. sol. ether.— $\text{B}^+\text{H}_2\text{PtCl}_6$ : orange-red pp.—Picrate: [202°].

(γγ)-**Dipyriddy**  $\text{C}_{10}\text{H}_8\text{N}_2$ . [114°]. (305° cor.). V.D. 5.9 (calc. 5.5). Formed by boiling pyridine with sodium (Anderson, *A.* 154, 274; Weidel a. Russo, *M.* 8, 854). Formed also by heating its (αα)-dicarboxylic acid with  $\text{HOAc}$  at 180° (Heuser a. Stoehr, *J. pr.* [2] 44, 407). Tables, sl. sol. cold water, v. sol. alcohol. Crystallises from water in tables (containing 2 aq). [73°]. Tastes bitter. Yields isonicotinic acid on oxidation. Br forms  $\text{C}_{10}\text{H}_7\text{Br}_2\text{N}_2$  crystallising from alcohol in needles. MeI and EtI form crystalline  $\text{B}^+\text{MeI}$  and  $\text{B}^+\text{EtI}$  respectively.

**Salts.**— $\text{B}^+\text{H}_2\text{Cl}_2$ . Monoclinic crystals;  $a:b:c = 1.064:1: .595$ .  $\beta = 112^\circ 33'$ .— $\text{B}^+\text{H}_2\text{ZnCl}_4$ .— $\text{B}^+\text{H}_2\text{HgCl}_4$ . Monoclinic tables;  $a:b:c = .673:1: .341$ ;  $\beta = 91^\circ 3'$ .— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{HNO}_3$ . [256°]. Trimetric prisms;  $a:b:c = .841:1: .397$ .— $\text{B}^+\text{HNO}_3\text{AgNO}_3$ .— $\text{B}^+\text{H}_2\text{SO}_4$  2 aq.

**Dihydride**  $\text{C}_{10}\text{H}_{10}\text{N}_2$ . *Dipyridine*. (290°) at 735 mm. V.D. 5.0 (calc. 5.5). Formed by the action of Na on pyridine (Anderson, *C. J.* 22, 406; Weidel, *M.* 8, 879). Liquid, sol. water and alcohol.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{MeI}$ .— $\text{B}^+\text{Me}_2\text{PtCl}_6$  (Ramsay, *C. J.* 36, 264).

**Hexahydride**  $\text{C}_{10}\text{H}_{12}\text{N}_2$ . *Isonicotine*. [78°]. (above 260°). Formed by reducing (γγ)-dipyriddy with tin and  $\text{HClAq}$  (W. a. R.). Deliquescent needles, sol. water, alcohol, and benzene. Has hardly any smell. Strongly alkaline and caustic. Poisonous, acting somewhat like curari. Its salts are much less poisonous. Oxidised by  $\text{KMnO}_4$  to isonicotinic acid.— $\text{B}^+\text{HNO}_3$ . Deliquescent needles.— $\text{B}^+\text{H}_2\text{PtCl}_6$  aq.— $\text{B}^+\text{H}_2\text{HgCl}_4$ .— $\text{B}^+\text{MeI}$ : triclinic prisms (from  $\text{MeOH}$ ).

**Dodecahydride**  $\text{C}_{10}\text{H}_{12}\text{N}_2$ . [122°]. Formed by reducing (γγ)-dipyriddy in alcohol by Na (Ahrens, *B.* 21, 2929). Needles, insol. water, v. sol. alcohol and ether.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .— $\text{B}^+\text{HAuCl}_4$ . *Picrate*: needles, blackening when heated.

**Dipyriddy**  $\text{C}_{10}\text{H}_8\text{N}_2$ . (281°). Formed by passing pyridine vapour through a red-hot tube (Roth, *B.* 19, 360). Oil.— $\text{B}^+\text{HCl}$ : hygroscopic needles.— $\text{B}^+\text{H}_2\text{PtCl}_6$ .—*Picrate*: [208°].

(αβ)-**Dipyriddy**  $\text{C}_{10}\text{H}_8\text{N}_2$ . (296° cor.). Formed by heating its carboxylic acid with lime (Skrap a. Vortmann, *M.* 3, 599; Blau, *B.* 24, 326). Oil, sol. alcohol and ether.— $\text{B}^+\text{H}_2\text{PtCl}_6$  ¾ aq.— $\text{B}^+\text{C}_6\text{H}_5\text{N}_3\text{O}_7$ . [149-5°]. Yellow needles.

**Dodecahydride**  $\text{C}_{10}\text{H}_{12}\text{N}_2$ . [69°]. (269° cor.). Formed by reducing the base with isoamyl alcohol and Na (Blau, *M.* 13, 332). Hygroscopic crystalline mass. Not identical with nicotine hexahydride. Strongly alkaline, absorbing  $\text{CO}_2$  from the air. V. e. sol. water, but much water gives a turbidity. V. sol. alcohol, m. sol. ether.  $\text{CS}_2$  forms a compound [205°].— $\text{B}^+\text{H}_2\text{Cl}_2$ . V. e. sol. water, sl. sol. alcohol and ether.— $\text{B}^+\text{H}_2\text{PtCl}_6$  2 aq. [238°].— $\text{B}^+\text{HHAuCl}_4$ . [212°].— $\text{B}^+\text{C}_6\text{H}_5\text{N}_3\text{O}_7$ . [215°].

**Benzene sulphonyl derivative**. [157°].

**Nitrosamine**  $\text{C}_{10}\text{H}_8\text{N}_2(\text{NO})$ . [88°].

**Dipyriddy dodecahydride?**  $\text{C}_{10}\text{H}_{12}\text{N}_2$ ? (251°). S.G. 1.956. Is perhaps (αβ)-dipyriddy hexahydride (Blau). Formed by the action of Na on nicotine in alcoholic solution (Liebrecht, *B.* 18, 2970; 19, 2590). Lavoratory liquid, v. sol. water, alcohol, and ether. Alkaline in reaction. Smells like piperidine. Readily unites with  $\text{CS}_2$ . Forms an oily nitrosamine and an oily di-acetyl derivative (c. 405°).— $\text{B}^+\text{HCl}$ . Sol. alcohol.— $\text{B}^+\text{H}_2\text{PtCl}_6$ . [202°].— $\text{B}^+\text{H}_2\text{I}$ : brown needles.—

$B''H_2AuCl_4$  [152°].— $B''H_2HgCl_4$ .— $B''Me_2PtCl_4$ .— $C_6H_5Me_2PtCl_4$ . Blau (M. 18, 841) by reducing nicotine obtained a mixture of bases (235°–265°) yielding a sparingly soluble platinochloride [218°], which gave a base (244°), possibly methyl-nicotine hexahydrate  $C_6H_5N_2$ .

(a)-PYRIDYL-ACRYLIC ACID  $C_6H_5NO_2$  i.e.  $C_6H_5N.CH.CH.CO_2H$  [203°]. Formed by heating  $\alpha$ -oxy-tri- $\omega$ -chloro-propyl-pyridine with alcoholic potash (Einhorn, B. 20, 1593; 23, 220; A. 265, 215). Got also by heating  $\alpha$ -oxy-pyridyl-propionic acid. Small transparent needles, v. sl. sol. cold water, v. sol. alcohol.

Reactions.—1. Br in HOAc forms  $C_6H_5N.CHBr.CHBr.CO_2H$  [127°], which melts at 146.5° when containing HOAc of crystallisation.—2. Hydrogen bromide in HOAc forms  $(C_6H_5N.CHBr.CHBr.CO_2H)HBr$  [164°], crystallising in needles.—3. MeI yields  $HA'MeI$  [220°] converted by AgBr into  $HA'MeBr$  [242°].

Salts.— $HA'HCl$ . [220°].— $H_2A'H_2PtCl_4$ . [210°]. Red prisms.— $HA'H_2AuCl_4$ . [195°].— $HA'HBBr$ . [223°].— $CaA'_2$ .— $AgA'$ : needles.

Methyl ether  $MeA'$ .— $MeA'HCl$ . [186°].— $MeA'HBBr$ . [242°].  $MeA'HI$ . [220°].

Ethyl ether  $EtA'$ . Needles.

(a)-PYRIDYL-BUTYLENE  $C_6H_5N$  i.e.  $C_6H_5N.CH.CHEt$ . (148° at 75 mm.). By distilling oxybutyl-pyridine  $C_6H_5N.CH_2.CH(OH).C_2H_5$  with KOH in *vacuo* or by heating it with  $HClAq$  at 165° (Matzdorff, B. 23, 2711). Colourless oil, smelling like conyryn. —Platinochloride: [140°].— $B''H_2AuCl_4$ . [130°]. Small needles.

(a $\beta$ )-DIPYRIDYL ( $\beta$ )-CARBOXYLIC ACID  $C_{11}H_8N_2O_2$  i.e.  $C_6H_5N.C_6H_5N.CO_2H$ . [183°]. Formed by heating the dicarboxylic acid at 200° (Skraup, B. 15, 896; M. 3, 597). Needles (containing  $1\frac{1}{2}$  aq), sl. sol. cold water and alcohol. Gives a yellow colour with  $FeCl_3$ .— $CaA'_2$ .— $AgA'_2$ : prismatic needles.

(a $\beta$ )-Dipyridyl ( $\beta$ )-dicarboxylic acid  
 $CH \begin{array}{c} \diagup \\ \text{CH} \end{array} \begin{array}{c} \diagdown \\ \text{CH} \end{array} \begin{array}{c} \diagup \\ \text{C} \end{array} \begin{array}{c} \diagdown \\ \text{C} \end{array} \begin{array}{c} \diagup \\ \text{CH} \end{array} \begin{array}{c} \diagdown \\ \text{CH} \end{array} \begin{array}{c} \diagup \\ \text{CH} \end{array}$

[215°]. Formed by oxidation of phenanthroline by  $KMnO_4$  (Skraup a. Vortmann, B. 15, 896; M. 3, 587). Triclinic prisms (containing 2aq), sl. sol. cold water, v. sol. alcohol.  $FeSO_4$  colours its aqueous solution red. Salts.— $KHA''$ : 1aq.— $CaA''$  8aq.— $CuA''$  3aq.— $BaA''$   $1\frac{1}{2}$ aq. Crystals.— $AgHA''$  4aq.— $H_2A''$  2HCl.— $H_2A''H_2PtCl_4$  3aq.— $(H_2A'')H_2PtCl_4$  6aq: golden prisms.

( $\beta\beta$ )-Dipyridyl ( $\alpha\alpha$ )-dicarboxylic acid  $C_{12}H_8N_2O_4$  [213°]. Formed by oxidation of pseudo-phenanthroline by  $KMnO_4$  (Skraup a. Vortmann, M. 4, 583). Thick prisms (containing  $\frac{1}{2}$  aq), sl. sol. cold water, alcohol, and ether.  $FeSO_4$  gives an orange-yellow colour.— $K_2A''$  6aq.— $KHA''$  2aq.— $CaA''$  5aq.— $CuA''$   $3\frac{1}{2}$ aq.— $Ag_2A''$   $\frac{1}{2}$ aq.— $Ag_2A''AgNO_3$ .— $HA'HCl$  aq. Monoclinic prisms;  $a:b:c = 1.27:1.29:2$ ;  $\beta = 110^\circ 16'$ .— $H_2A''H_2PtCl_4$  8aq: orange crystalline pp.

( $\gamma\gamma$ )-Dipyridyl ( $\alpha\alpha$ )-dicarboxylic acid. [247.5°]. Formed by oxidising ( $\alpha\alpha$ )-di-methyl-dipyridyl by  $KMnO_4$  (Heuser a. Stoehr, J. pr. [2] 44, 405). Needles, v. sl. sol. water and alcohol.  $FeSO_4$  gives a reddish-yellow colour.  $AcOH$  at 180° gives ( $\gamma\gamma$ )-dipyridyl.

Dipyridyl tetracarboxylic acid? [96°]. Got by oxidising diquinolyl (Claus, B. 14, 1942). Needles (from hot water).— $Pb_2A''$ .— $Ag_2A''$ .

## PYRIDYLENE-PHENYLENE-KETONE

### PHENYLENE-PYRIDYL KETONE.

Pyridylene-phenylene-ketone sulphonic acid

$\left[ \begin{array}{c} 3 \\ 2 \end{array} \right] C_6H_4(SO_3H) < \begin{array}{c} CO.CN-CH \\ C-C_6H_4.CH \end{array}$  Formed by oxidising ( $\beta$ )-naphthoquinoline sulphonate with alkaline  $KMnO_4$  (Immerheiser, B. 23, 408). Yellow plates (from water), v. sl. sol. alcohol and ether. Yields an oxim crystallising in yellow flakes and a phenyl-hydrazide crystallising in minute orange needles.— $KA'$  aq.— $BaA'_2$  2aq.— $PbA'_2$  3aq.— $AgA'$  aq.

PYRIDYL-ETHYLENE  $C_6H_5N.CH.CH_2$ . (160°). Formed by the action of  $NaOHAq$  on the hydrochloride of  $\beta$ -bromo- $\beta$ -pyridyl-propionic acid (Einhorn, B. 23, 221; A. 265, 229). Liquid.— $B''H_2AuCl_4$ . [144°]. Yellow needles.

(a)-PYRIDYL ETHYL KETONE  $C_6H_5NO$  i.e.  $C_6H_5N.CO.C_2H_5$ . (205°). Formed by distilling calcium picolinate with calcium propionate (Engler a. Bauer, B. 24, 2530). Oil, sol. alcohol. Sodium-amalgam forms a pinacone [186°]. Phenyl-hydrazine sulphonic acid yields a crystalline compound [268°].— $B''HgCl_2$ : crystalline.— $B''EtL$ . [160°].

Oxim  $C_6H_5N.C(NOH).C_2H_5$ . [106°]. Needles. Yields an acetyl derivative [46°] and a benzoyl derivative [69°].

( $\beta$ )-Pyridyl ethyl ketone  $C_6H_5N.CO.C_2H_5$ . Formed by distilling calcium nicotinate with calcium propionate (Engler, B. 24, 2539). Yields a phenyl hydrazide [145°] and a phenyl-hydrazide sulphonate [235°] which forms  $B''H_2PtCl_4$ .  $B''C_6H_5N_2O_2$ , and  $B''HgCl_2$  [130°].

Oxim  $C_6H_5N.C(NOH).C_2H_5$ . [115°].

(a)-PYRIDYL METHYL KETONE  $C_6H_5N.CO.CH_3$ . (192°). Formed by distilling calcium picolinate with calcium acetate (Engler a. Rosumoff, B. 24, 2527). V. sol. alcohol and ether. Readily volatile with steam. Yields an oxim [120°], a phenyl-hydrazide [155°], and a phenyl-hydrazide sulphonate which is not melted at 300°.— $B''C_6H_5N_2O_2$ . [131°].— $B''HgCl_2$ . [150°].— $B''MeI$ . [161°].— $B''EtL$ . [205°].

( $\beta$ )-Pyridyl methyl ketone  $C_6H_5N.CO.CH_3$ . (220°). Formed by distilling calcium nicotinate with calcium acetate (Engler a. Kiby, B. 22, 597). Oil, v. sol. acids. Yields an oxim [112°], which yields  $B'HCl$  [204°]. The phenyl-hydrazide [137°] crystallises from alcohol in yellow needles.— $B''HgCl_2$ . [158°]. White needles.

DI-(a)-PYRIDYL-PROPANE  $C_{11}H_{12}N_2$  i.e.  $CH_3(CH_2)_2C_6H_5N_2$ . (323°). S.G.  $\frac{1}{4}$  1.0281. Formed by heating picoline with methylal and  $ZnCl_2$  for 10 hours at 290° (Ladenburg, B. 21, 3100). Yellow oil, v. sol. alcohol and ether.—Salts:  $B''H_2PtCl_4$ . [215°].— $B''2H_2AuCl_4$   $1\frac{1}{2}$ aq.— $B''H_2HgCl_4$ . [161°]. Large plates.

Dodecahydride  $C_{12}H_{18}N_2$ . Dipipecolyl-methane. [54°]. (195° at 26 mm.). Formed by reducing the base with Na and alcohol. Crystalline mass, sl. sol. water.— $B''2HCl$ : very hygroscopic needles.— $B''2MeCl$ . [171°].— $C_{12}H_{18}Me_2N_2$  2MeI. Crystals, v. a. sol. water.

### (a)-PYRIDYL PROPYL KETONE

$C_6H_5N.CO.Pr$ . (216°–220°). Formed by distilling calcium picolinate with sodium butyrate (Engler a. Majum, B. 24, 2536). Oil. Yields an oxim [48°] which forms a benzoyl derivative [57°]. Forms a phenyl-hydrazide [82°] and a

phenyl-hydrazide sulphonic acid [251°]. The ketone is reduced, in dilute alcoholic solution, by sodium-amalgam to a pinacone  $C_{18}H_{21}N_4O_2$  [146°]. The chloro-iodide melts at 85°.

**Salts.**— $B_2H_4PtCl_6$ .— $B'HgCl_2$ . [c. 78°].— $B'MeI$ . [79°].

( $\beta$ )-Pyridyl propyl ketone  $C_8H_9N.CO.Pr$ . (246°-252°). Formed by distilling calcium nicotinate with calcium butyrate (Engler, *B.* 24, 2541). Yellow needles, sol. alcohol. Yields a phenyl-hydrazide [182°], a phenyl-hydrazide sulphate [283°], a crystalline oxim, and an ethyl-iodide [192°].— $B'HgCl_2$ . [173°].— $B'C_6H_5N_2O_4$ .

( $\beta$ )- $\alpha$ -PYRIDYL-QUINOLINE  $C_{11}H_{10}N_2.i.e.$   
 $CH.CH.C.OH:CH$   
 $CH.N.CO.CH:C_6H_5N$  [104°]. Formed by heating the Ag salt of its carboxylic acid (O. Fischer a. H. van Loo, *B.* 19, 2475). Prisms.— $B'H_2PtCl_6$ .

Carboxylic acid  $C_{11}H_{10}N_2O_2.i.e.$

$C_6H_5N.C \begin{smallmatrix} CH:CH \\ N-CH \end{smallmatrix} > C.CO_2H$ . [273°]. Formed by oxidising ( $\beta$ )-diquinolyl with  $CrO_3$ . Needles, v. sl. sol. water.—AgA': pale yellow pp.

**PYRO.** Use of this prefix applied to inorganic compounds; for pyro-compounds v. the compounds to the names of which pyro-is prefixed. Thus pyro-phosphoric acid will be found under PHOSPHORIC ACID, and pyro-phosphates under PHOSPHATES.

**PYROCATECHIN**  $C_8H_6O_2.i.e. C_6H_4(OH)_2[1:2]$ . *Catechol*. *o*-Di-oxy-benzene. *Oxyphenic acid*. [104°] (F. a. M.); [111°] (Mortinon). (240°-245°). H.C.p. 685,200. I.L.C.v. 684,900. H.F. 85,800 (Stohmann, *J. pr.* [2] 45, 334). Occurs in urine, especially after administration of benzene or phenol (Baumann, *H.* 1, 244; 3, 157; Nencki a. Giacomini, *H.* 4, 335; Schmiedeborg, *H.* 6, 189). Occurs in the green leaves of the Virginia creeper (*Ampelopsis hederacea*) (Gorup-Besanez, *B.* 4, 905) and in the sap of the plants from which kino is prepared (Flückiger, *B.* 5, 1). Occurs sometimes in raw beet sugar (Lippmann, *B.* 20, 3298). Occurs in wood-tar (Béhal a. Desvignes, *Bl.* [3] 9, 144).

**Formation.**—1. By dry distillation of catechin, moritannic acid, and all varieties of tannin that turn green with  $FeCl_3$  (Zwenger, *A.* 37, 327; Wagner, *J. pr.* 52, 450; 55, 65; Eissfeldt a. Uloth, *A.* 92, 101; 111, 215).—2. By the dry distillation of wood (Buchner, *A.* 96, 188).—3. By heating cellulose, starch, or cane sugar with water at 200°-280° (Hoppe-Seyler, *B.* 4, 15).—4. By potash-fusion from *o*-iodo-phenol (Körner, *Bull. Acad. Belg.* [2] 24, 166; Lautemann, *A.* 120, 315).—5. By the action of HI on guaiacol (Gorup-Besanez, *J.* 1867, 688; Baeyer, *B.* 8, 155).—6. By the dry distillation of protocatechuic acid and of quinic acid (Strecker, *A.* 118, 285; Hasiwetz a. Barth, *J.* 1864, 405; Tiemann a. Haarmann, *B.* 7, 617).—7. By potash-fusion from *o*-phenol sulphonic acid (Kekulé, *Z.* 1867, 643), benzoic acid, gum guaiacum (Hasiwetz a. Barth, *A.* 130, 352; 134, 282), and together with resorcin, from *o*- and *m*-bromo-phenol (Fittig, *B.* 8, 364).—8. By soda-fusion from phenol (Barth a. Schreder, *B.* 12, 419).—9. From phenol and  $H_2O_2$  (Martinon, *Bl.* [2] 43, 157).—10. By passing a rapidly alternating electric current through a solution of phenol.—11. A

product of the action of water at 200° on benzene hexachloride (Meunier, *C. R.* 100, 1591).

**Preparation.**—1. From HIAq and guaiacol at 200° or by heating guaiacol with conc. HClAq for 4 hours at 175° (Perkin, jun., *C. J.* 57, 587). 2. By fusing *o*-phenol sulphonic acid with potash at 350° (Degener, *J. pr.* [2] 20, 308).

**Properties.**—Large plates (from benzene) or needles (from water), v. sol. water, alcohol, and ether, m. sol. benzene and chloroform, insol. ligroin. Gives an acid reaction in presence of borax (Lambert, *C. R.* 108, 1017).  $FeSO_4$  gives no colour.  $FeCl_3$  colours the aqueous solution green, turned violet-red by alkalis (Ebstein a. Müller, *Fr.* 15, 465). The alkaline solution absorbs oxygen, becoming brown. It reduces  $AgNO_3$ ,  $AsCl_3$ , and platinum chloride. Ppts. a conc. solution of egg-albumen. Does not ppt. gelatin. Lead acetate gives a white pp. Quinone in ethereal solutions forms  $C_6H_4O.C_6H_5O_2$ , crystallising in deep-green needles with violet lustre [153°] (Clermont a. Chantard, *C. R.* 102, 1072). Ppts. a solution of quinine sulphate, forming  $C_{20}H_{24}N_4O_4.H_2SO_4.C_6H_5O_2$  aq, which separates from alcohol in yellow crystals [167°], v. sl. sol. cold water.

**Reactions.**—1. Nitric acid acts violently, forming oxalic acid.—2. Phthalic anhydride and  $ZnCl_2$  at 150° form 'pyrocatechin phthalein'

$C_6H_4 \begin{smallmatrix} CO.O \\ \diagup \quad \diagdown \end{smallmatrix} C(C_6H_4(OH)_2)_2$ , a yellow mass forming a blue solution in alkalis and yielding a tetra-benzoyl derivative [202°] (Baeyer a. Kochendörfer, *B.* 22, 2196).—3. Phenyl cyanate at 100° forms  $C_6H_4(O.CO.NHPh)_2$  [165°] crystallising in needles, v. sol. alcohol (Snape, *C. J.* 47, 772).—4. The disodium compound  $C_6H_4(ONa)_2$ , treated with  $CO_2$  in the cold forms  $C_6H_4(O.CO_2Na)_2$ , which at 100° changes to the compound  $C_6H_4(O.CO_2Na)(OH).CO_2Na$  and at 210° to  $C_6H_4(OH)_2(CO_2Na)_2$  (Schmitt a. Hühle, *J. pr.* [2] 44, 2).—5. Ammonium carbonate and water at 140° react forming protocatechuic acid and  $C_6H_4(OH)(CO_2H)_2[1:2:3]$ .—6.  $K_2S_2O_8$  acting on K salt forms crystalline  $C_6H_4(O.SO_3K)_2$  and  $C_6H_4(OH)(O.SO_3K)$  (Baumann, *B.* 11, 1913).—7.  $Cl.CO.NH_2$  forms  $C_6H_4(O.CONH_2)_2$  [178°] crystallising from alcohol in needles.—8. Chlorine passed into its solution in acetic acid forms

$CCl \begin{smallmatrix} CCl.CCl_2 \\ \diagdown \quad \diagup \end{smallmatrix} CO$  crystallising (with 2aq) from ether-ligroin, and from ligroin (with aq), melting at 94° (Zincke a. Klein, *B.* 21, 2719).—9. KOH and  $ClCO_2Et$  form  $C_6H_4CO_2$  [118°] (Bender, *B.* 13, 697), (225°-230°) (M. Wallach, *A.* 226, 84).

**Estimation.**—By extracting its acidified aqueous solution with ether, evaporating the ether, dissolving the residue in water, and precipitating with lead acetate. The pp. is dried at 100° and weighed (Degener, *J. pr.* [2] 20, 303).

**Salt s.**— $C_6H_4O_2.Pb$ . White pp.— $C_6H_4O_2.Sb$  or  $C_6H_4 \begin{smallmatrix} O \\ \diagup \quad \diagdown \end{smallmatrix} SbOH$ . Formed by adding  $SbCl_3$  to a

solution of pyrocatechin saturated with NaCl (Causse, *Bl.* [3] 7, 245). Prisms, insol. water, alcohol, and ether, sol. alkalis and mineral acids.  $As_2O_3$  at 125° forms  $C_6H_4(OAc)_2$  and  $Sb(OH)(OAc)_2$ .

**Di-acetyl derivative**  $C_6H_4(OAc)_2$ . Needles (Nachbauer, *A.* 107, 248).

**Di-benzoyl derivative**  $C_6H_4(OBz)_2$  [84°]. Plates (Doeberner, A. 210, 261; Hinsberg, A. 254, 254).

**Mono-methyl ether**  $C_6H_4(OH)(OMe)$ . *Guaiacol*. Mol. w. 124. [285°]. (Tiemann a. Koppe, B. 14, 2016; Béhal a. Choay, Bl. [3] 9, 142). S.G.  $d_4^{20}$  1.125 (V.);  $d_4^{15}$  1.153;  $d_4^{15}$  1.143 (B. a. G.). A product of distillation of gum guaiacum (Sobrero, A. 48, 19; Deville a. Pelletier, A. 52, 403; Völckel, A. 89, 349). Occurs among the products of the distillation of wood (Hlasiwetz, A. 106, 362; Gorup-Besanez, A. 143, 151). Prepared by heating calcium vanillate with slaked lime (Tiemann, B. 8, 1123) and by heating pyrocatechin with MeI and  $K_2SO_4$  (Gorup-Besanez, A. 147, 248, or with NaOMe, MeOH, and MeI). Liquid, with peculiar odour, sol. alcohol and ether, sl. sol. water, sol. dry glycerin and ligroin.  $FeCl_3$  gives a green colour in its alcoholic solution. Dissolves in alkalis. Yields  $C_6H_5.OMe$  on heating with zinc-dust (Marasse, A. 152, 64).  $PCl_5$  forms  $C_6H_4.Cl.OMe$  (Fischli, B. 11, 1463). I and KOHAq give a coffee-brown pp. [125°–130°] (Messinger a. Vortmann, B. 22, 2320). The K salt is converted by aceto-chlorohydrate into  $C_6H_4(OMe)(O.C_2H_5O_2)$  [157°] (Michael, Ann. 6, 339). Phthalic anhydride and  $SnCl_4$  at 115° form 'guaiacol-phthalein,' which yields a crystalline benzoyl derivative (Baeyer, B. 22, 2199).  $H_2SO_4$  forms two sulphonie acids (Tikmann a. Koppe, B. 14, 2019).— $C_6H_4(OH)(OMe)2aq.$ — $KHA_2$  aq: prisms (from alcohol), decomposed by water.— $Pb(OH)A'$ : flocculent pp.— $C_6H_4(O.SO_3K)(OMe)$ : white needles.— $C_6H_4(OAc)(OMe)$ . [235°–240°]. V.D. 82.7 (obs.). Colourless liquid.

**Di-methyl ether**  $C_6H_4(OMe)_2$ . *Veratrole*. (205°). V.D. 68.6 (obs.;  $H=1$ ). S.G.  $d_4^{20}$  1.086. Formed by heating veratric acid with baryta (Merk, A. 108, 60; Koelle, A. 159, 243; Tiemann, B. 14, 2016). It is obtained also from  $C_6H_4(OH)(OMe)$  and MeI (Marasse). Solidified at 15°.

**Methyl ethyl ether**  $C_6H_4(OMe)(OEt)$ . (213°). V.D. ( $H=1$ ) 75.6 (obs.). Liquid.

**Methyl propyl ether**  $C_6H_4(OMe)(OPr)$ . (240°–245°). Liquid (Calours, Bl. [2] 29, 270).

**Di-ethyl ether**  $C_6H_4(OEt)_2$ . [44°]. Formed from pyrocatechin, EtI, and alcoholic potash (Herzog a. Zeisel, M. 10, 152).

**Di-benzyl derivative**  $C_6H_4(OC_6H_5)_2$ . [61°]. Yellowish needles (from alcohol). Forms a nitro-derivative crystallising in needles [98°].

The *mono-benzyl derivative* is liquid, but its nitro-derivative forms yellow needles (from alcohol) [129°] (Schiiff a. Pellizzari, A. 221, 378; G. 13, 507).

**Sulphonic acid**  $C_6H_4(OH)(SO_3H)[4:3:1]$ . Formed by fusing phenol ( $\alpha$ )-disulphonic acid with KOH at 300° (Barth a. Schmidt, B. 12, 1260). Deliquescent needles, v. sol. water and alcohol, insol. ether.— $KA'$ .— $NaA'$  aq.— $BaA'$ .

**References.**—AMIDO-, BROMO-, CHLORO-, and NITRO-PYROCATECHIN, and TRI-BROMO-GUAIACOL.

**PYROCINCHONIC ACID** v. DI-METHYLMALIC ACID.

**PYROCOLL**  $C_6H_4N_2O_2$  (Magnanini, B. 22, 2502). [269°]. A product of the distillation of gelatin when free from fat but containing albumen, casein, or gluten (Weidel a. Ciamician, M. 1, 275; 2, 29). Formed also, together with

HOAc, by heating the acetyl derivative of pyrrole ( $\alpha$ )-carboxylic acid (Ciamician a. Silber, B. 17, 103; G. 14, 162, 563). Colourless plates, insol. water and cold alcohol, sl. sol. ether. Sublimes before fusion.

**Reactions.**—1. Boiling KOHAq converts it into pyrrole carboxylic acid.—2. Alcoholic  $NH_3$  forms the amide of pyrrole carboxylic acid.—3.  $PCl_5$  forms  $C_6H_4Cl_2N_2O$  (above 320°) insol. ether and  $C_6H_4Cl_2N_2O$  [197°] sol. ether (Ciamician a. Danesi, G. 13, 28). The perchloro-pyrocoll  $C_6H_4Cl_2N_2O_2$  is converted by boiling KOHAq into tri-chloro-pyrrole carboxylic acid, and by  $PCl_5$  into  $C_6H_4Cl_3N_2O$  [147°].—4. Bromine forms  $C_6H_4Br_2N_2O$  [192°],  $C_6H_4Br_2N_2O_2$  [290°], and  $C_6H_4Br_2N_2O_2$ , which is converted by KOHAq into di-bromo-pyrrole carboxylic acid (Ciamician, G. 11, 330; 12, 29; B. 16, 2388).

**Reference.**—CHLORO-, BROMO-, and NITRO-PYROCROLL.

**PYROCRESCOL**  $C_{13}H_{10}O$ ? An inappropriate name given by Schwarz (B. 15, 2201; 16, 2141; M. 3, 726; cf. Armstrong, C. J. Proc. 3, 114) to some neutral substances found in coal-tar.

( $\alpha$ )-Pyrocresol [195°]. Thin silvery plates, yielding crystalline  $C_{13}H_{10}Br_2O_2$ ? and oxidised by  $CrO_3$  in HOAc to  $C_{13}H_{10}O_2$  [168°] which yields  $C_{13}H_{10}(NO_2)_2O_2$  [235°],  $C_{13}H_{10}(NO_2)_2O_2$  and  $C_{13}H_{10}(NH_2)_2O_2$  [300°]? (Bott a. Miller, G. J. 55, 52). Chlorine acting on a solution of ( $\alpha$ )-pyrocresol in chloroform gives  $C_{13}H_{11}Cl_3O$  [225°]? HI reduces ( $\alpha$ )-pyrocresol to a hydrocarbon  $C_{13}H_{10}$ ? (Bott, C. J. Proc. 3, 114).

( $\beta$ )-Pyrocresol [c. 124°]. Yields, on oxidation, ( $\beta$ )-Pyrocresol oxide  $C_{13}H_{12}O_2$  [95°].

( $\gamma$ )-Pyrocresol [165°]. Yields ( $\gamma$ )-pyrocresol oxide [77°] on oxidation. Bromine forms  $C_{13}H_{10}Br_2O_2$ ? crystallising in trimetric plates.

**PYROGALLIC ACID** v. PYROGALLOL.

**PYROGALLOL**  $C_6H_3O_3$ , i.e.  $C_6H_4(OH)[1:2:3]$ . *c-Tri-oxy-benzene*. *Pyrogallol acid*. Mol. w. 126. [131°] (Etti, B. 11, 1889; cf. Stenhouse, A. 179, 236); [134°] (Stohmann). (210°). S. 40 at 12°. H.C.p. 633,300 (Berthelot a. Louguinine, A. Ch. [6] 13, 339; C. R. 104, 1577). H.F. (from diamond) 137,700 (B. a. L.); 132,000 (Stohmann, J. pr. [2] 45, 336). Occurs in wood-tar as dimethyl ether.

**Formation.**—1. By heating gallic acid (alone or mixed) with pumice stone (2 pts.) (Braconnot, A. 1, 26; Pelouze, A. 10, 159; Liebig, A. 101, 47).—2. By heating di-iodo-o-oxy-benzoic acid with KOHAq (Lautemann, A. 120, 299).—3. By heating ( $\alpha$ )- or ( $\beta$ )-chloro-phenol sulphonic acid with KOH at 190° (Petersen a. Baehr, A. 157, 136).—4. By heating gallic acid (10 g.) with glycerin (30 c.c.) at 200° as long as  $CO_2$  comes off (Thorpe, Ph. [3] 11, 990).—5. By heating gallic acid (1 pt.) with aniline (2 pts.) at 120° (Cazeneuve, Bl. [3] 7, 549). The product is aniline pyrogallate  $C_6H_3O_3.2NPhH$  [56°], which gives off aniline when exposed to air, or when shaken with benzene.

**Properties.**—Prisms, v. s.l. water, m. sol. alcohol and ether. Tastes bitter. Poisonous (Personne, Z. [2] 5, 728). Its alkaline solution rapidly absorbs oxygen, turning brown, and giving off a little CO in bulk about  $\frac{1}{30}$ th of the oxygen absorbed (Calvert a. Cloez, A. 130, 248). Reduces  $KMnO_4$  (Monier, C. R. 46, 577) and salts of mercury, Ag, Au, and Pt.  $FeSO_4$  gives

a white milkiness, but if a ferric salt is present, or the pyrogallol solution has become slightly oxidised by keeping,  $\text{FeSO}_4$  gives an indigo-blue colour, changing to brownish-red on standing and on adding  $\text{HCl}$  (Jacquemin, *C. R.* 77, 593; Cazeneuve, *Bl.* [2] 44, 114; *C. R.* 101, 56).  $\text{FeCl}_3$ , in absence of air, gives a transient blue colour, restored by cautious addition of alkali. A solution of pyrogallol renders borax slightly acid (Lambert, *C. R.* 108, 1017). Nitrous acid colours the aqueous solution brown (Schönbein, *Fr.* 1, 319).  $\text{K}_2\text{CrO}_4$  and  $\text{H}_2\text{SO}_4$  give a dark colour. Reduces  $\text{CuSO}_4$  and, on addition of alkalis, gives a black colour changed by  $\text{NH}_3$  to red.  $\text{Cu}(\text{OAc})_2$  gives at once a black colour. Pyrogallol fused with ammonium oxalate yields ammonium rufogallate, which dissolves in water with red colour and gives with  $\text{K}_2\text{FeCy}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  a dark-brown pp. insol. alcohol (Kliebahn, *Fr.* 26, 641). A solution of iodine in presence of  $\text{Na}_2\text{SO}_4$  gives a purple colour (Nasse, *B.* 17, 1186). A solution of  $\text{HgCl}_2$  and pyrogallol in alcohol gives a black pp. with alkaloids but not with glucosides (Schlagdenhaufen, *Ph.* [3] 4, 772). An alkaline solution of pyrogallol absorbs about 50 vols. of  $\text{NO}$  in 12 hours, but no  $\text{N}_2\text{O}$  (Russell a. Lapraik, *C. J.* 32, 85). Pyrogallol does not react with hydroxylamine (Baeyer, *B.* 19, 163). A solution of potassium pyrogallate which is absorbing oxygen in contact with alumina gives out a feeble light, especially in presence of  $\text{Na}_2\text{S}$  (Lenard a. Wolf, *P.* [2] 34, 918).

**Reactions.**—1. Fuming  $\text{HNO}_3$  forms oxalic acid.—2. Bromine forms tri-bromo-pyrogallol.—3. Chlorine in presence of  $\text{HOAc}$  forms mairougallol (vol. iii. p. 165) and crystalline leucogallol  $\text{C}_6\text{H}_4\text{Cl}_2\text{O}_2$ , 2aq, which yields tri-chloro-pyrogallol when boiled with water and zinc-dust (Stenhouse a. Groves, *C. J.* 28, 706; Webster, *C. J.* 45, 208; Hantzsch a. Schnitzer, *B.* 20, 2033).—4. Ozone passed through a solution of pyrogallol (1 mol.) and  $\text{KOH}$  (3 mols.) in water forms a syrupy acid  $\text{C}_6\text{H}_4\text{O}_5$ , which yields  $\text{BaC}_6\text{H}_4\text{O}_5$  (Boeke, *B.* 6, 486).—5. Purpurogallin or pyrogalloquinone is formed by oxidation by alcoholic  $\text{AgNO}_3$ , by  $\text{KMnO}_4$  and  $\text{H}_2\text{SO}_4$ , or by excess of  $\text{FeCl}_3$  (Girard, *C. R.* 69, 865). It is also got from pyrogallol and quinone (Wichelhaus, *B.* 5, 847; Nietzki, *B.* 20, 1278). It forms garnet-red needles (by sublimation), sl. sol. water, m. sol. alcohol and ether, forming yellow solutions. Alkalis impart a transient blue colour. Purpurogallin dyes cotton mordanted with alumina violet-blue. When an aqueous solution of pyrogallol is mixed with gum arabic and exposed to the air, purpurogallin  $\text{C}_{20}\text{H}_{14}\text{O}_8$  separates, the yield in the course of two months being 67 p.c. of the pyrogallol used (Struve, *A.* 163, 160; De Clermont a. Chataud, *C. R.* 94, 1189, 1254). A solution of pyrogallol and  $\text{Na}_2\text{HPO}_4$  also yields pyrogalloquinone on exposure to air (Loew, *J. pr.* [2] 15, 322). Purpurogallin forms  $\text{C}_{20}\text{H}_{14}\text{Ac}_2\text{O}_8$  and  $\text{C}_{20}\text{H}_{14}\text{Br}_2\text{O}_8$ .—6. An ammoniacal solution exposed to the air forms brown pyrogallein  $\text{C}_{18}\text{H}_{12}\text{O}_{10}$  (Rösing, *J.* 1858, 259).—7. Ammonium carbonate at  $130^\circ$  forms pyrogallol carboxylic acid  $\text{C}_6\text{H}_4\text{O}_5$  (v. Traut-Ox-Benzoin acid) and pyrogallol dicarboxylic acid  $\text{C}_6\text{H}_2\text{O}_7$  (270°) (Senhofer a. Brünner, *M.* 1, 488).—8. Distillation over zinc-dust yields benz-

ene.—9.  $\text{ClCO}_2\text{Et}$  acting on the K salt forms  $\text{C}_6\text{H}_4\text{O}_5$  [105°] converted by aniline into diphenyl-urea and the mono-ethyl ether of pyrogallol (Bender, *B.* 13, 698).—10. A few drops of  $\text{POCl}_3$  added to a mixture of pyrogallol (3 pts.) and acetone (1 pt.) react violently, forming gallacetone  $\text{C}_{10}\text{H}_{10}\text{O}_3$ , which crystallises from 15 p.c. alcohol in whetstone-shaped crystals, insol. water, decomposing about  $250^\circ$ , and yielding  $\text{C}_6\text{H}_4\text{AcO}_2$  (Wittenberg, *J. pr.* [2] 26, 76). Its solutions are turned purple by  $\text{FeCl}_3$  and reduce  $\text{AgNO}_3$ .—11. A few drops of  $\text{H}_2\text{SO}_4$  added to a mixture of pyrogallol (12 g.) and acetoacetic ether (8 g.) form di-oxy-methyl-coumarin  $\text{C}_{10}\text{H}_8\text{O}_3$ , which crystallises from water in needles [235°] and yields  $\text{C}_{10}\text{H}_8\text{AcO}_3$  [176°] (Wittenberg, *J. pr.* [2] 26, 68; Pechmann, *B.* 16, 2127; 17, 2188).—12. *Phthalic anhydride* forms, on heating,  $\text{C}_{20}\text{H}_{10}\text{O}$  (Baeyer, *B.* 4, 457, 663; *A.* 209, 261).—13. *Phenyl cyanate* at  $100^\circ$  forms  $\text{C}_6\text{H}_4(\text{O.CO.NHPH})_2$  [173°] crystallising in minute needles (Snape, *C. J.* 47, 774).—14. *Cyanogen* passed into an aqueous solution forms  $\text{C}_6\text{H}_4\text{O}_5\text{Cy}$ , or a polymeride thereof, as an unstable crystalline pp. (Loew, *J. pr.* [2] 15, 326).—15. *Chloroacetic acid* (2½ pts.) followed by  $\text{NaOHAq}$  forms  $\text{C}_6\text{H}_4(\text{O.CH}_2\text{CO}_2\text{H})_2$  crystallising in needles [198°], S. 1:3 at  $145^\circ$  and yielding  $\text{K}_2\text{A}''$  and  $\text{KH}_2\text{A}''$  aq (Giaccosa, *J. pr.* [2] 19, 398).—16. *Benzotrichloride* at  $160^\circ$  yields 'pyrogallol-benzenein'  $\text{C}_{20}\text{H}_{12}\text{O}_3$ , crystallising in minute red plates with green lustre forming a blue solution in alkalis and a bluish-violet solution in alcohol. Zinc and  $\text{HOAc}$  reduce it to the anhydride of hexa-oxy-diphenyl-methane. Pyrogallol-benzenein yields  $\text{C}_{20}\text{H}_{12}\text{AcO}_3$  [208°],  $\text{C}_{20}\text{H}_{12}\text{BzO}_3$  [251°],  $\text{C}_{20}\text{H}_{12}\text{O}_3(\text{C}_6\text{H}_5)_2$  [228°] (Döbner a. Förster, *A.* 257, 60).—17. *Benzoic acid* and  $\text{ZnCl}_2$  at  $145^\circ$  form tri-oxy-benzophenone (*Alizarin yellow A*)  $\text{C}_6\text{H}_3(\text{OH})_3\text{CO.C}_6\text{H}_5$  [141°], which crystallises with aq. The same body is got by heating pyrogallol with benzotrichloride (*G. P.* 50,451 [1889] and 54,661 [1890]; Graebe a. Eichengrün, *A.* 269, 297).—18. On heating pyrogallol with *salicylic acid* and zinc chloride tetra-oxy-benzophenone  $\text{C}_6\text{H}_2(\text{OH})_4\text{CO.C}_6\text{H}_3(\text{OH})_3$  [149°] is formed (G. a. E.).—19.  $\text{Ac}_2\text{O}$  forms  $\text{C}_{10}\text{H}_{10}\text{O}$  [280°] crystallising in white prisms (Causse, *Bl.* [3] 3, 867). Fuming  $\text{HClAq}$  at  $170^\circ$  forms  $\text{C}_6\text{H}_4\text{O}_5$  as a black powder, sol.  $\text{NaOHAq}$  (Böttlinger, *A.* 202, 280).—20. *Benzene sulphonic chloride* added to a solution of pyrogallol kept slightly alkaline forms  $\text{C}_6\text{H}_3(\text{O.SO}_2\text{Ph})_2$  [142°], sol. alcohol, sl. sol. ether (Georgesen, *B.* 24, 418).—21. *Formic aldehyde* and dilute  $\text{HClAq}$  form  $\text{CH}_2(\text{C}_6\text{H}_4(\text{OH})_3)_2$ , a microcrystalline powder, insol. water, sol. alcohol (Caro, *B.* 25, 947).—22. *Aldehyde* and dilute  $\text{H}_2\text{SO}_4$  mixed with  $\text{Na}_2\text{SO}_4$  added slowly at  $60^\circ$  gives colourless crystals of  $\text{C}_6\text{H}_4\text{O}_5$  2aq, which when dried at  $30^\circ$  over  $\text{H}_2\text{SO}_4$  leaves violet  $\text{C}_6\text{H}_4\text{O}_5$  aq (Causse, *Bl.* [3] 3, 865; cf. Michael a. Ryder, *Am.* 9, 133).—23. *Benzoic aldehyde* and a large quantity of  $\text{HClAq}$  form amorphous  $\text{C}_{20}\text{H}_{12}\text{O}$  (Baeyer, *B.* 5, 280). Benzoic aldehyde, alcohol, and a little conc.  $\text{HClAq}$  form a pp. of  $\text{C}_{20}\text{H}_{12}\text{O}_3$ , which yields  $\text{C}_{20}\text{H}_{12}\text{AcO}_3$  (Michael a. Ryder, *Am.* 9, 130). On heating with benzoic acid alone pyrogallol forms resinous  $\text{C}_{20}\text{H}_{12}\text{O}$ , and red  $\text{C}_{20}\text{H}_{12}\text{O}_3$ , which may be reduced to colourless  $\text{C}_6\text{H}_4\text{O}_5$  (Baeyer, *B.* 5, 26).—24.  $\text{KOH}$  (83 pts.) and  $\text{K}_2\text{S}_2\text{O}_8$  (70 pts.) heated

with water (33 pts.) and pyrogallol (25 pts.) at 70° form  $C_6H_2(OH)_2(O_2SO_2K)$ , crystallising in needles, v. s. sol. water (Baumann, *B.* 11, 1913).—25.  $ClCONH_2$  forms  $C_6H_2(O_2CO.NH_2)_2$ , [178°], crystallising from alcohol in plates.

**Salts.**— $C_6H_2(OH)_2(ONH_4)$ . Crystals, got by passing  $NH_3$  into an ethereal solution of pyrogallol (De Luynes, *A. Suppl.* 6, 252).— $C_6H_2(OH)_2(O_2Pb)aq$ . Crystalline pp. got by adding lead nitrate to ammonium pyrogallol. Converted by conc.  $NH_3aq$  into  $C_6H_2O_3PbO$ .— $(C_6H_2O_3)Pb.OAc$ . Ppd. by adding lead acetate to a solution of pyrogallol (Deering, *C. J.* 26, 702).— $C_6H_2(SbO)_2$ . Plates, got by ppg. pyrogallol solution with tartar-emetic (Rösing).  $SbCl_3$  (100 g.) dissolved in a saturated solution (250 c.c.) of  $NaCl$ , filtered, and slowly added to pyrogallol (50 g.) dissolved in saturated  $NaClaq$  (250 g.), forms a white pp. which changes to crystals of  $C_6H_2(OH)_2\left<\begin{smallmatrix} O \\ O \end{smallmatrix}\right>SbOH2aq$ , insol. water

and alcohol, sol. mineral acids (Causse a. Bayard, *B.* [3] 7, 794). At 100° the above liquids on mixing yield  $C_6H_2O_3Sb$ , which is also crystalline, whence  $Ac_2O$  at 100° forms  $C_6H_2O_3Ac$ ,  $AcCl$  in  $Ac_2O$  converts both antimonites into  $C_6H_2(OAc)_2$ .— $C_6H_2O_32PbII_2$ . [56°] (Mylus, *B.* 19, 1003).

**Acetyl derivative**  $C_6H_2(OAc)_2$ . Got from pyrogallol and  $AcCl$  (Nachbauer, *A.* 107, 244).

**Benzoyl derivative**  $C_6H_2(OBz)_2$ . [90°]. Got, together with a mono- or di-benzoyl derivative [131-5°], from pyrogallol and  $BzCl$  (Skraup, *M.* 10, 391).

**Di-methyl ether**  $C_6H_2(OH)(OMe)_2$ . [52°]. (253°). Occurs in beech-wood creosote (Hofmann, *B.* 11, 333; 12, 1373). Formed from pyrogallol (1 mol.),  $KOH$ , and  $MeI$  (2 mols.) at 160°. Prisms (from water). Its alkaline solution does not turn brown in air. Oxidised by means of  $K_2Cr_2O_7$  and  $HOAc$  to œserulignone  $C_{12}H_8O_4(OMe)_2$ . Yields  $C_6H_2(OAc)(OMe)_2$  as a sticky mass, and  $C_6H_2(OBz)(OMe)_2$ . [118°].

**Tri-methyl ether**  $C_6H_2(OMe)_3$ . [47°]. (235°). Formed by the action of  $MeI$  and  $KOH$  on pyrogallol dissolved in  $MeOH$  (Will, *B.* 21, 607). Needles, insol. water and alkalis, v. sol. alcohol and ether. Yields  $C_6Br_2(OMe)_2$ , [81°]. Conc.  $HNO_3$  forms  $C_6H_2(NO_2)_2(OMe)_2$ , [100°] and the di-methyl derivative of dioxiquinone.

**Mono-ethyl ether**  $C_6H_2(OH)(OEt)_2$ . [95°]. Formed, together with the di- and tri-ethyl ethers, by heating pyrogallol with  $KOH$  and  $KEtSO_4$  at 100° (Benedikt, *B.* 9, 125; *M.* 2, 212; Hofmann, *B.* 11, 797). Needles, m. sol. water, v. s. sol. alcohol and ether.  $FeSO_4$  gives a bluish-violet colour. Volatile with steam.

**Di-ethyl ether**  $C_6H_2(OH)(OEt)_2$ . [79°]. (262°). Crystals (from dilute alcohol). Oxidised by  $K_2Cr_2O_7$  and  $HOAc$  to ethyl-œserulignone. Nitrous acid passed into an ethereal solution forms  $C_{10}H_{12}O_4HNO_2$ , which forms a brown solution in water.

**Tri-ethyl ether**  $C_6H_2(OEt)_3$ . [89°]. Got from pyrogallol, alcoholic potash, and  $EtI$  (Herzig a. Zeisel, *M.* 10, 151). Needles, insol.  $KOHaq$ .

**Ethylene ether**  $C_6H_2(OH)_2O_2C_2H_4$ . (267°). Formed from pyrogallol, alcoholic potash, and ethylene bromide (Magatti, *B.* 12, 1860). Yields  $O_2H_2(OBz)_2O_2C_2H_4$ , [109°].

**References.**—AMIDO-, BROMO-, CHLORO-, and NITRO-PYROGALLOL.

**PYROGALLOL CARBOXYLIC ACID v. GALLIC ACID.**

**Pyrogallol dicarboxylic acid**  $C_6H_2(OH)_2(CO_2H)_2$  [1:2:3:4:5]. *Gallocarboxylic acid*. [270°]. S. °5 at 0°. H.C. 633,700. H.F. 231,300 (Stohmann, *J. pr.* [2] 40, 128). Formed by heating pyrogallol or gallic acid with ammonium carbonate at 130° (Senhofer a. Brunner, *M.* 1, 468). Needles (containing 3aq), sl. sol. cold water. • Gives a violet colour with  $FeCl_3$ .— $K_2A''2aq$ : needles.— $BaA''aq$ .— $CaA''6aq$ .— $Ag_2A''$ .

**PYROGALLOL SULPHONIC ACID**  $C_6H_2SO_3$ , i.e.  $C_6H_2(OH)_2SO_3H$  3aq. Formed by dissolving pyrogallol in  $H_2SO_4$  (Personne, *B.* [2] 12, 169; 20, 531; Schiff, *A.* 178, 179). Hygroscopic crystals.— $KA''2aq$ : prisms, v. sol. water. Converted by heating with  $POCl_3$  into  $C_6H_2S_2O_5$ , a flocculent mass, v. sol. alcohol, which is converted by warming with  $HOAc$  and  $Ac_2O$  into crystalline  $C_6H_2Ac_2S_2O_{11}$  and  $C_6H_2Ac_4S_2O_{11}$ .

**PYROGALLOQUINONE v. PYROGALLOL, Reaction 5, and PURPURATION.**

**PYROGENTISIC ACID** is HYDROQUINONE.

**PYROGLUTAMIC ACID** is OXY-TETRAMETHENYL DIHYDRIDE CARBOXYLIC ACID.

**PYROGLYCERIN v. DIGLYCERIN.**

**PYROGUAIACIN**  $C_{15}H_{10}O_4$ , i.e.  $C_{15}H_8O_4(OH)_2$ , [180-5°]. (258°) at 80 mm. V.D. 9-53 (calc. 9-76). A product of the distillation of gum guaiacum (Pelletier a. Deville, *C. R.* 17, 1143; Ebermaier, *J. pr.* 62, 291; Nachbauer, *A.* 106, 332; Hlasiwetz, *A.* 106, 381; 119, 277; Wieser, *M.* 1, 594). Plates, v. sl. sol. hot water, sl. sol. alcohol and ether. Forms a blue solution in  $H_2SO_4$ . On distillation with zinc-dust it yields guaiene  $C_{15}H_{12}$ , [100°], which is converted by oxidation into a lemon-yellow quinone  $C_{15}H_8O_4$ , [121°]. Potash-fusion forms  $C_{15}H_{10}O_2$ , [202°], which is reduced by zinc-dust to guaiene. Pyroguaiacin yields  $C_{15}H_{14}AcO_2$ , [122°],  $C_{15}H_{16}Br_2O_2$ , [179°],  $C_{15}H_{18}Br_2O_2$ , [172°], and the salt  $C_{15}H_{16}K_2O_4$ .

**PYROLIC ACID v. SEBACIC ACID.**

**PYRO-MECAZONIC ACID**  $C_6H_4NO_2$ . Formed by heating oxycomenic acid, with  $NH_3aq$  and also, in small quantity, along with the isomeric amido-pyro-mecanic acid, by the reduction of nitro-pyromecanic acid. Prepared from oxy-pyro-mecazonic acid by reducing with  $HI$  (Ost, *J. pr.* [2] 19, 203; 23, 441; 27, 258).

**Properties.**—Streaked trimetric tablets. Combines with mineral acids, but not with acetic acid. Gives rise to a di-acetyl derivative [155°] and a bromo-derivative  $C_6H_4BrNO_2$ . Is stable in acid solutions, but soon turns brown in alkaline solution. Gives a blue colour with  $FeCl_3$ .  $BaCl_2$  and  $NH_3$  give a pp. which turns bright blue in air.

**Reactions.**—1. Suspended in ether and mixed with  $HNO_3$  forms 'pyromecazone'  $C_6H_4NO_2$ . Pyromecazone is a brick-red powder, insol. ether, v. sol. water, gives no colour with  $FeCl_3$ , and turns the skin violet. With  $BaCl_2$  and  $NH_3$  it gives, on exposure to air, a crimson pp. Crystallises from alcohol as  $C_6H_4NO_2.EtOH$ . Aqueous  $SO_2$  converts pyromecazone back into pyromecazonic acid. These properties resemble those of a quinone.—2. Suspended in  $HOAc$  and

treated with  $\text{HNO}_3$  it forms yellowish prisms of nitro-pyromecazone  $\text{C}_6\text{H}_4(\text{NO}_2)\text{NO}_2$  aq. This body is decomposed by water at  $30^\circ$  into nitro-pyromecazonic acid  $\text{C}_6\text{H}_4(\text{NO}_2)\text{NO}_2$ ,  $\text{CO}_2$  coming off through oxidation of some of the substance.  $\text{SO}_2$  rapidly changes nitro-pyromecazone into nitro-pyromecazonic acid, so that the former resembles quinone in its ready reducibility. Nitro-pyromecazonic acid gives a blood-red colour with  $\text{FeCl}_3$ , nitro-pyromecazone gives no colour with  $\text{FeCl}_3$ . It yields the salt  $\text{C}_6\text{H}_3\text{NaNa}_2\text{O}_7$ .

Salt.— $\text{HA}'\text{HCl}$  aq: needles.

**Oxyppymecazonic acid**  $\text{C}_6\text{H}_3\text{NO}_4$ . Formed by passing  $\text{SO}_2$  into an ethereal solution of nitrosopyromecazonic acid, and boiling the product (v. Nitroso-pyromecazonic acid) with  $\text{CHCl}_3$  (Ost, *J. pr.* [2] 19, 177). Needles (containing aq or 2aq). Coloured dirty-violet by  $\text{FeCl}_3$ .— $\text{NaHA}'_2$ .— $\text{KHA}'_2$ .— $\text{TiHA}'_2$ .— $\text{CaA}'_2$ .— $\text{HA}'\text{HCl}$ .

**PYROMECONIC ACID**  $\text{C}_6\text{H}_4\text{O}_3$ . [117°]. (225° uncor.).

**Preparation.**—By distillation of meconic acid in a current of  $\text{CO}_2$ , some comenic acid being also formed (Ost, *J. pr.* [2] 19, 182; 23, 441; cf. Robiquet, *A.* 5, 90; *A. Ch.* [2] 5, 282; 51, 236; Stenhouse, *P. M.* [3] 24, 128; *A.* 49, 18; F. D. Brown, *P. M.* [4] 4, 161; 8, 201; *A.* 84, 32; 92, 321; Ihlé, *A.* 188, 31). The yield is 14 p.c.

**Properties.**—Glittering prisms from water or alcohol. V. sol. chloroform, much less sol. ether. Gives a blood-red colour with  $\text{FeCl}_3$ . Feeble acid. Does not react with hydroxylamine (Oderheimer, *B.* 17, 2081). Bromine forms  $\text{C}_6\text{H}_3\text{BrO}_3$ , crystallising in prisms and yielding  $\text{PbA}'_2$  aq. Excess of Br yields  $\text{C}_6\text{H}_3\text{BrO}_3$  aq [109°].  $\text{ICl}$  forms  $\text{C}_6\text{H}_3\text{IO}_3$ , yielding  $\text{BaA}'_2$  aq and  $\text{PbA}'_2$ .

**Salts.**—Forms two series of unstable salts, alkaline to litmus:  $\text{KA}'$ .— $\text{HNaA}'_2$ .— $\text{BaA}'_2$  3aq. — $\text{BaHA}'_2$ .— $\text{CaA}'_2$  aq.— $\text{CaHA}'_2$ .— $\text{MgA}'_2$ .— $\text{SrA}'_2$  aq.— $\text{PbA}'_2$ .— $\text{FeA}'_2$ .— $\text{CuA}'_2$ .— $\text{C}_6\text{H}_3\text{O}_3\text{HCl}$ . Formed by passing  $\text{HCl}$  into ethereal solution of the acid. Decomposed into its constituents by water or alcohol. Sulphates  $\text{C}_6\text{H}_3\text{O}_3\text{H}_2\text{SO}_4$  and  $(\text{C}_6\text{H}_3\text{O}_3)_2\text{H}_2\text{SO}_4$ . Got by adding  $\text{H}_2\text{SO}_4$  to an ethereal solution (Ost, *J. pr.* [2] 19, 189).

**Acetyl derivative**  $\text{C}_6\text{H}_3\text{AcO}_3$ . [91°]. Obtained by warming with  $\text{AcCl}$ .

**Nitroso-pyromecazonic acid**  $\text{C}_6\text{H}_3(\text{NO})\text{O}_3$ . An unstable compound of this body with an equivalent of pyromecazonic acid is formed by passing  $\text{N}_2\text{O}$  into an ethereal solution of that acid (Ost, *J. pr.* [2] 19, 195). An aqueous solution of  $\text{SO}_2$  converts this compound by addition of  $\text{H}_2$  into  $\text{C}_6\text{H}_3(\text{NO})\text{O}_3\text{C}_6\text{H}_3\text{O}_3$ , a compound which is split up by boiling chloroform, leaving so-called oxy-mecazonic acid,  $\text{C}_6\text{H}_3\text{NO}_4$ . This acid gives a violet colour with  $\text{FeCl}_3$ , and a blue pp. with  $\text{BaCl}_2$  and  $\text{NH}_3$ . By Sn and  $\text{HCl}$  it is reduced to pyromecazonic acid  $\text{C}_6\text{H}_3\text{NO}_3$ .

**References.**—AMIDO- and NITRO-PYROMECANIC ACID.

**PYROMELLITIC ACID**  $\text{C}_6\text{H}_2\text{O}_4$ . [238°]. Obtained in the electrolysis of aqueous  $\text{KOH}$  with carbon electrodes, and got also by oxidation of mellogen by  $\text{KOC}$  (Bartoli a. Papasogli, *G.* 12, 113; 13, 51). Crystalline (containing 2aq), sol. water and alcohol. Yields the crystalline salt  $\text{C}_6\text{H}_2\text{Na}_2\text{O}_4$  and an ethyl ether crystallising in colourless needles (below  $100^\circ$ ), insol. water.

**PYROMELLITIC ACID**  $\text{C}_6\text{H}_2\text{O}_4$ , i.e.  $\text{C}_6\text{H}_2(\text{CO}_2\text{H})_4$  [1:2:4:5]. Mol. w. 254. [264°]. S. 14.2 at  $16^\circ$ . H.C.p. 777,400 (Stohmann, *J. pr.* [2] 40, 140; 43, 540). H.C.v. 778,900. H.F. 869,600. Formed by gently distilling mellitic acid (Erdmann, *A.* 80, 281) and by oxidising *s*-durene (Jacobsen, *B.* 17, 2517). Crystallises from water in triclinic tables (containing 2aq), v. sol. hot water. Forms various compounds on heating with (a)-naphthol (Grabowski, *B.* 4, 726; 6, 1065).— $\text{CaA}'_2$  6aq.— $\text{PbA}'_2$  aq.— $\text{AgA}'_2$ : pp.

**Methyl ether**  $\text{MeA}'_2$ . [138°]. Plates, sl. sol. hot alcohol (Baeyer, *A.* 166, 359).

**Ethyl ether**  $\text{EtA}'_2$ . [53°]. Formed from the Ag salt and  $\text{EtI}$  (Baeyer, *A. Suppl.* 7, 36). Needles (from alcohol).

**Chloride**  $\text{C}_6\text{H}_2(\text{COCl})_4$ . Got by heating the acid with  $\text{PCl}_5$ . Crystalline mass, v. sol. ether.

**Anhydride**  $\text{C}_6\text{H}_2(\text{C}_2\text{O}_3)_2$ . [268°]. Got by distilling the acid. Needles (by sublimation), v. sol. hot water, being re-converted into the acid.

**Tetrahydride**  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_4$ . Formed by the action of sodium-amalgam on the ammonium salt of pyromellitic acid (Baeyer). Amorphous hygroscopic mass, v. sol. water. When heated with  $\text{H}_2\text{SO}_4$  it yields pyromellitic, trimellitic, and isophthalic acids.

**Iso-tetrahydride**  $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_4$ . [above  $200^\circ$ ]. Accompanies the preceding acid. Needles (containing 2aq). Behaves like the preceding hydride when heated with  $\text{H}_2\text{SO}_4$ . Yields a methyl ether [156°] which may be distilled.

**References.**—AMIDO- and NITRO-PYROMELLITIC ACID.

**PYROMUCIC ACID**  $\text{C}_6\text{H}_3\text{O}_4$ , i.e.

$\text{CH}_3\text{CH} \begin{matrix} \nearrow \text{C.CO}_2\text{H} \\ \searrow \text{CH.O} \end{matrix}$  *Furfuran* (a)-carboxylic acid. Mol. w. 112. [132°]. S. 3.6 at  $15^\circ$ ; 25 at  $100^\circ$ . R<sub>100</sub> 40.18 (in a 2.19 p.c. aqueous solution).

**Formation.**—1. By the distillation of mucic acid (Houton-Labillardière, *A. Ch.* [2] 9, 365; Pelouze, *A.* 9, 273; Boussingault, *A.* 15, 184; Liès-Bodart, *A.* 100, 327).—2. By distilling dehydromucic acid (Heinzelmann, *A.* 193, 184).—3. By oxidation of furfuraldehyde by  $\text{Ag}_2\text{O}$  (Schwanert, *A.* 114, 63; 116, 257).—4. Together with furfuryl-carbinol by boiling furfuraldehyde with alcoholic potash (Ulrich, *Z.* 1861, 186; Schmelz a. Beilstein, *A. Suppl.* 3, 275; Limprieh, *A.* 165, 279).—5. By distilling isosaccharic acid in a current of  $\text{CO}_2$  (Tiemann a. Haarmann, *B.* 19, 1271).—6. Occurs, together with pyromucic acid  $\text{C}_6\text{H}_3\text{NO}_4$  [165°] which yields  $\text{BaA}'_2$  1aq, in the urine of dogs dosed with furfuraldehyde (Jaffé a. Cohn, *B.* 20, 2311).

**Preparation.**—By oxidising furfuraldehyde with alkaline  $\text{KMnO}_4$  below  $20^\circ$  (Volhard, *A.* 261, 879).

**Properties.**—Long white needles (by sublimation), v. sol. alcohol and ether.  $\text{FeCl}_3$  gives no colour.

**Reactions.**—1. Bromine in excess forms mucobromic acid. Dry Br gives  $\text{C}_6\text{H}_3\text{BrO}_4$  [160°], oxidised by dilute  $\text{CrO}_3$  to di-bromopyromucic acid (Tönnies, *B.* 11, 1086).—2. Distillation with soda-lime yields furfuran. —3. On heating with lime and ammonia-zinc-chloride it yields pyrrole.

**Salts.**— $\text{KA}'$ : needles.— $\text{NaA}'$ .— $\text{BaA}'_2$ : crys-

ials, sol. water and alcohol.— $\text{CaA}'_2$ : crystalline powder.— $\text{CuA}'_2$  3aq.— $\text{PbA}'_2$  2aq.— $\text{AgA}'$ : scales.

*Ethyl ether EtA'*. [34°]. (209°). Laminae, v. sol. alcohol and ether, insol. water (Malaguti, A. 25, 276). Combines with dry chlorine, forming  $\text{C}_2\text{H}_3\text{Cl}_3\text{O}_2$ . S.G.  $\frac{100}{1}$  1.496. Dry Br forms  $\text{C}_2\text{H}_3\text{Br}_3\text{O}_2$  [48°] (Tönnies) and also the ethers of ( $\beta$ )-di-bromo-pyromucic acid [167°], of ( $\beta$ )-di-bromo-pyromucic acid [192°] and of ( $\delta$ )-bromopyromucic acid [183°] (Hill a. Sanger, A. 232, 65).

*Chloride*  $\text{C}_2\text{H}_3\text{O}_2\text{Cl}$ . (170°).

*Amide*  $\text{C}_2\text{H}_3\text{O}_2\text{CONH}_2$ . [143°]. Formed from the ether or chloride and  $\text{NH}_3\text{Aq}$  (Wallach, B. 14, 751; 214, 227; Ciamician a. Dennstedt, B. 14, 1058; G. 11, 291). Large plates, sol. alcohol, sl. sol. ether. Converted by  $\text{PCl}_5$  or  $\text{P}_2\text{O}_5$  into the nitrile.

*Ethylamide*  $\text{C}_2\text{H}_3\text{O}_2\text{CONHEt}$ . [258° cor.]. Formed from pyromucic ether and ethylamine solution at 100°. Converted by  $\text{PCl}_5$  into crystalline  $\text{C}_2\text{H}_3\text{O}_2\text{CCl}_2\text{NHEt}$ .  $\text{PCl}_5$  in smaller quantity ( $\frac{1}{3}$  pt.) forms the amidine  $\text{C}_2\text{H}_3\text{O}_2\text{C(NEt)}_2\text{NHEt}$ , a liquid (240°) which gives  $\text{B}^+\text{H}_2\text{P}_4\text{Cl}_2$ .

*Anilide*  $\text{C}_2\text{H}_3\text{O}_2\text{CONiPh}$ . [123°5']. Long needles (Schiff, B. 19, 849).

*Nitrile*  $\text{C}_2\text{H}_3\text{O}_2\text{CN}$ . *Furfuryl cyanide*. (148°). Liquid with sweet taste, sl. sol. water, smelling like benzoic aldehyde. On reduction it gives  $\text{C}_2\text{H}_3\text{O}_2\text{CH}_2\text{NH}_2$ .

( $\beta$ )-Pyromucic acid, got by oxidation of fucosol, is a mixture of pyromucic acid with methyl-pyromucic acid [108°] (Bieler a. Tollens, A. 258, 126).

*Isopyromucic acid*. [82°]. Formed, together with pyromucic acid, in the distillation of mucic acid. It decomposes  $\text{BaCO}_3$  very slowly, and can be separated by shaking the product with  $\text{BaCO}_3$  and extracting with ether (Limpricht, A. 165, 256). Plates (by sublimation), v. e. sol. water, alcohol, and ether.  $\text{FeCl}_3$  gives a green colour. Br yields mucobromic acid.

*References.*—Bromo-, Bromo-sulpho-, Chloro-, Nitro-, and Sulpho-pyromucic acids.

**PYROMUCIC ALDEHYDE** v. FURFURALDEHYDE.

**PYROMYKURIC ACID**  $\text{C}_2\text{H}_3\text{NO}_3$ . [165°]. Occurs in the urine of rabbits dosed with furfuraldehyde (Jaffé a. Cohn, B. 20, 2311). Prisms (from water). Split up by boiling baryta-water into glycooll and pyromucic acid.— $\text{BaA}'_2$  1 $\frac{1}{2}$ aq: plates.—A urea compound  $(\text{C}_2\text{H}_3\text{NO}_3)\text{CO(NH}_2)_2$  [120°] occurs in the urine of dogs fed with meat. It crystallises from benzene in needles, v. sol. water and alcohol, sl. sol. ether, and is decomposed by heating with  $\text{BaCO}_3$  into urea and pyromykuric acid.

**PYRONE.** A name given to the ring  $\text{CO} \begin{array}{c} \diagup \text{CN:CH} \\ \diagdown \text{CH:CH} \end{array} \text{O}$ .

**PYROPHORUS.** Any finely-divided substance which takes fire very easily when exposed to air is called a *pyrophorus*.

**PYROBACEMIC ACID** is PYRUVIC ACID.

**PYROTARTARIC ACID**  $\text{C}_2\text{H}_2\text{O}_4$  i.e.

$\text{CO}_2\text{H.CHMe.CH}_2\text{CO}_2\text{H}$ .

*Methyl-succinic acid*. Mol. w. 132. [115°]. S.G. 66 at 20°. S.H. 3098 (from 0° to 50°) (Hess, A. Ch. [2] 85, 410). H.C.v. and p. 515,200

(Stohmann, J. pr. [2] 40, 209); 511,672 (Louguine, C. R. 107, 597). H.F. 230,800 (S.).

*Formation.*—1. By dry distillation of tartar (Valentin Rose, *Gehlen's Journ.* 3, 598) and of tartaric and racemic acids (Graver, N. J. T. 24, 2, 55; Pelouze, A. Ch. [2] 56, 297; Wemisselos, A. 15, 148; Fourcroy a. Vauquelin, A. Ch. 35, 161; Gt. 42; Arppe, A. 66, 73).—2. By the reduction of ita-, citra-, and mesa-conic acids and of dibromopyrotartaric acid with sodium-amalgam (Kekulé, A. Suppl. 1, 342; 2, 95).—3. By saponifying its nitrile with  $\text{HClAq}$  (Maxwell Simpson, A. 121, 161).—4. By heating powdered tartaric acid with  $\text{HClAq}$  at 180° (Geuther a. Riemann, Z. [2] 5, 318).—5. By potash-fusion from gamboge (Hlasiwetz a. Barth, A. 138, 73).—6. By heating pyruvic acid alone at 170° or with  $\text{HClAq}$  at 100°, or by boiling it with baryta. 7. By boiling  $\beta$ -acetyl- $\alpha$ - or  $\beta$ -methyl-succinic ether with potash (Conrad, A. 188, 217; Kressner, A. 192, 135).—8. By heating allyl iodide (1 mol.) with  $\text{KCy}$  (2 mols.) and a little alcohol, and boiling the resulting nitrile with  $\text{KOH}$  (Claus, B. 5, 612; 8, 100; A. 91, 38).—9. By heating propane tricarboxylic acid (Bischoff a. Guthzeit, B. 20, 614).—10. By oxidation of  $\beta$ -acetyl- $n$ - and *iso*-butyric acid (Bischoff, A. 206, 337).

*Properties.*—Triclinic prisms grouped like frog's feet (from ether), v. sol. water, alcohol, and ether. Begins to boil at 200°, yielding an anhydride together with some butyric acid (Claus, A. 191, 48). Its solution is not ppd. by lime-water or lead acetate, but gives a pp. with lead subacetate.

*Reactions.*—1. Bromine acts very slowly in the cold, but when the acid (10 pts.) is heated with Br (21 pts.) and water (10 pts.) at 120° for 6 hours bromocitraconic anhydride is formed (Lagermark, Z. 6, 299). When the acid (1 mol.) is heated with Br (4 mols.) at 132° acetylene tetrabromide is formed (Bourgoin, A. Ch. [5] 12, 419).—2. The K salt yields, on electrolysis, O, CO, and  $\text{CO}_2$  at the positive pole (Reboul a. Bourgoin, C. R. 84, 1231).—3. Distillation with  $\text{P}_2\text{S}_5$  yields methyl-thiophene.—4. On heating the acid (5 pts.) with resorcin (9 pts.) and  $\text{H}_2\text{SO}_4$  (18 pts.) at 150° there is formed pyrotartaryl-fluorescein  $\text{C}_{17}\text{H}_{13}\text{O}_6$ , a brownish-red powder, sl. sol. water, v. sol. dilute acids and alkalis. Its dilute alkaline solutions fluoresce yellowish-green. It yields  $\text{C}_{17}\text{H}_{13}\text{Br}_3\text{O}_6$  (Hjelt, B. 17, 1280).

*Salts.*— $\text{KA}'$  aq: deliquescent.— $\text{KHA}'$ : monoclinic prisms.— $\text{NaA}'$  6aq: efflorescent laminae.— $\text{NaHA}'$ : small prisms.— $(\text{NH}_4)_2\text{A}'$ : deliquescent; gives off  $\text{NH}_3$  on evaporation, leaving  $(\text{NH}_4)\text{HA}'$ , which crystallises from water in prisms, permanent in the air.— $\text{BeA}'$ .— $\text{BeHA}'$ .— $\text{CaA}'$  2aq: powder. S. l. at 100°.— $\text{CaH}_2\text{A}'$  2aq.— $\text{SrA}'$  aq.— $\text{SrA}'$  2aq.— $\text{SrH}_2\text{A}'$  2aq.— $\text{BaA}'$  2aq.— $\text{BaH}_2\text{A}'$  aq.— $\text{BaH}_2\text{A}'$  2aq.— $\text{BaH}_2\text{A}'$  3aq.— $\text{BaH}_2\text{A}'$  4aq.— $\text{MgA}'$  3aq.— $\text{MgA}'$  6aq.— $\text{Al(OH)A}'$ .— $\text{BiA}'$ .— $(\text{HO})_2\text{O}$ .— $\text{CdA}'$  3aq.— $\text{CdA}'$  2aq.— $\text{MnA}'$  3aq.— $\text{CuA}'$  2aq.— $\text{Cu}_2(\text{OH})_2\text{A}'$ .— $\text{Fe(OH)A}'$  2aq.— $\text{PbA}'$  2aq.— $\text{Pb}_2\text{A}'\text{O}_2$ .— $\text{NiA}'$  2aq.— $\text{NiH}_2\text{A}'$  2aq.— $\text{ZnA}'$  3aq.— $\text{Ag}_2\text{A}'$ : white curdy pp., blackened by light.

*Ethyl ether EtA'*. (218° cor.). S.G.  $\frac{15}{15}$  1.0189;  $\frac{25}{25}$  1.0113. M.M. 9347 at 174° (Perkin, C. J. 45, 516; cf. Malaguti, A. 25, 274).

**Chloride**  $C_4H_2O_4Cl_2$  (190°–193°) (Hjelt, B. 16, 2624). Reduced in ethereal solution by sodium-amalgam and HOAc to liquid  $C_4H_2O_4$  (204°). S. 20, which is the anhydride of an acid  $C_4H_2O_5$ .

**Anhydride**  $C_4H_2O_5$  (245° cor.) (Lebedeff, A. 182, 327). Got by heating the acid at 200° alone or with  $P_2O_5$ . Heavy oil, slowly converted by water into the acid.

**Amide**  $CH_3CH(CO.NH_2).CH_2.CONH_2$ . [175°]. S. 7 at 10°. Large plates (Henry, C. R. 100, 943).

**Imide**  $CH_3CH<\begin{smallmatrix} CO.NH \\ CH_2.CO \end{smallmatrix}$  [66°]. Formed by heating acid ammonium pyrotartrate (Arppe, A. 87, 228). Six-sided trimetric plates, sol. water, alcohol, and ether.

**Di-methylamide**  $C_2H_4(CO.NHMe)_2$ . [115°] (Henry, Bl. [2] 43, 619).

**Mono-anilide**  $CO_2H.CH_2.CHMe.CONHPh$ . [147°]. Formed from aniline and pyrotartaric anhydride in chloroform (Arppe, A. 90, 141; Anschütz, A. 246, 122). Got also by reducing the anilide of mesaconic acid with sodium-amalgam. Is identical with Reissert's 'pyranil-pyric lactone dihydride.' Bulky needles, m. sol. water.—PbA<sub>2</sub>: white pp.—AgA'.

**Phenyl-imide**  $CH_3CH<\begin{smallmatrix} CO.NPh \\ CH_2.CO \end{smallmatrix}$  [98°] (Arppe, A. 90, 139); [104°] (Biffi, A. 91, 105). Formed by heating the acid with aniline at 100° for ten minutes. Minute needles.

**p-Nitro-anilide**  $C_6H_4(CO_2H)(CO.NH.C_6H_4.NO_2)$ . [above 150°]. Formed by boiling the p-nitro-phenyl-imide with  $Na_2CO_3$  aq. Minute tables, v. sl. sol. hot water.—AgA': white pp.

**p-Nitro-phenyl-imide**  $C_6H_4.C_6H_4.NO_2.NC_6H_4.NO_2$ . [155°]. Formed by nitrating the phenyl-imide. Needles (from alcohol), almost insol. water.

**p-Bromo-anilide**  $C_6H_4(CO_2H).CO.NHC_6H_4.Br$ . [158°]. Formed from the anhydride and p-bromo-aniline (Anschütz a. Hensel, A. 248, 269).

**Di-bromo-anilide**  $C_6H_4(CO_2H).CO.NHC_6H_4.Br$ . [1:2:4]. [139°].

**Nitrile**  $CH_3CH(CN).CH_2.CN$ . [c. 12°]. (254°). Formed, amongst other products, by the action of KCN on allyl chloride (Pinner, B. 12, 2053). Prisms. Prepared from propylene bromide and alcoholic KCy at 100° (Maxwell Simpson, A. 121, 160). Liquid, sol. water, alcohol, and ether.

**Ethyl ether of the seminitrile**  $CO_2Et.CH_2.CHMe.CN$ . (198). S.G. 1.0275. V.D. 4.6. Formed from α-bromo-propionic ether and alcoholic KCy (Zelinsky, B. 21, 3162). Oil.—NaA': very hygroscopic.

**References.**—Bromo-, Chloro-, Iodo-, Oxy-amido-, and Oxy- PYROTARTARIC ACID.

**n-Pyrotartaric acid v. GLUTARIC ACID.**  
**Isopyrotartaric acid v. DI-METHYL-MALONIC ACID.**

**PYROTEREBIC ACID v. HEXENOIC ACID.**  
**PYROTRITARIC ACID**  $C_4H_2O_4$ , i.e.

$O<\begin{smallmatrix} CMe:CH \\ CMe:CO.OH \end{smallmatrix}$  Uvic acid. **Di-methyl-furfurene carboxylic acid.** Mol. w. 140. [135°]. S. 28 at 100°. A product of the distillation of tartaric acid (Wislicenus a. Stadnicki, A. 146,

806). Prepared by heating pyruvic acid with NaOAc and Ac<sub>2</sub>O at 140°, the yield being 20 p.c. (Böttger, B. 13, 1969; A. 172, 241; 208, 122; 247, 255), by heating pyruvic acid (30 g.) with dry sodium succinate (55 g.) at 110° (Fittig a. Parker, A. 267, 212), and by heating pyruvic acid (17.5 g.) with dry potassium propionate (20 g.) at 140° (Bischoff, B. 24, 2021). Formed also by heating methronic acid as long as CO<sub>2</sub> is given off (Fittig, A. 250, 190; cf. Harrow, C. J. 33, 425). Needles (from hot water), nearly insol. cold water, v. sol. alcohol and ether. Not affected by potash-fusion. PCl<sub>5</sub> gives a chloride, reconverted by water into the acid. Does not react with hydroxylamine or phenyl-hydrazine. Water at 160° forms acetonyl-acetone. By bromine it is converted into a tetra-bromo-derivative and its tetra-bromide, which are both reduced back to pyrotartaric acid by sodium-amalgam. An excess of bromine at 100° forms penta-bromo-pyrotartaric acid. By dry distillation it gives di-methyl-furfurane, a substance which is also obtained by distilling acetonyl-acetone with ZnCl<sub>2</sub> (Paal, B. 20, 1074; Dietrich a. Paal, B. 20, 1077).

**Salts.**—NaA' 2aq.—CaA' 2aq: prisms.—CaA' 4aq.—CaA' 6aq.—BaA' 4aq: plates.—BaA' 2aq.—BaA' 6aq.—ZnA' 8aq.—AgA'.

**Methyl ether** MeA'. (192°). Got by distilling the Ag salt of carbopyrotartaric monomethyl ether (Knorr a. Cavallo, B. 22, 156).

**Ethyl ether** EtA'. (208°).

**Pyrotartaric carboxylic acid v. METHRONIC ACID.**

**Carbopyrotartaric acid v. DI-METHYL-FURFURANE CARBOXYLIC ACID.**

**PYROXANTHIN**  $C_{15}H_{12}O_4$ . [162°]. Extracted by NaOH aq from the product of the dry distillation of wood (Scanlan, J. pr. 7, 94; Gregory, A. 21, 143; Hill, Am. 3, 332; B. 11, 456). Orange needles (from alcohol), sol. benzene and HOAc. Forms a purple solution in H<sub>2</sub>SO<sub>4</sub>. Reduced by zinc-dust and HOAc to a colourless body. Bromine forms  $C_{15}H_{10}Br_2O_4$  crystallising in small colourless triclinic needles, converted by alcohol and powdered Sb into  $C_{15}H_{10}Br_2O_4$  crystallising in yellow monoclinic needles, v. sol. hot alcohol.

**PYROXYLIN v. CELLULOSE.**

**PYRRODIAZOLE**  $C_4H_3N$ , i.e.  $N<\begin{smallmatrix} CH:N \\ CH:NH \end{smallmatrix}$  [121°]. Formed by heating its carboxylic acid at 120° (Andreocci, B. 25, 229). Needles, v. e. sol. water and alcohol.

**Pyrrrodiazole carboxylic acid**

$CO_2H.C<\begin{smallmatrix} N.NH \\ N.CO \end{smallmatrix}$  Formed by oxidising methyl-pyrrrodiazole with alkaline KMnO<sub>4</sub>. White crystalline powder, v. sl. sol. water, alcohol, and ether.

**PYRROLE**  $C_4H_3N$  i.e.  $\begin{smallmatrix} CH:CH \\ CH:CH \end{smallmatrix}>NH$ . **Pyrrhol.**  
**Pyrroline.** Mol. w. 67. (180° i.V.). S.G. 0.9752. S.V. 92.1 (Ramsay). H.F.p. 4,056 (Ramsay). Occurs among the products of distillation of coal (Runge, P. 31, 67) and of bones (Anderson, Tr. E. 20 [2] 247; 21 [4] 571; A. 80, 63; 105, 349).

**Formation.**—1. By distilling ammonium mucate alone or with glycerin at 190° (Schwanert, A. 116, 279; Goldschmidt, Z. [2] 3, 280).—2. By heating its carboxylic acid.—3. By distilling

succinimide with zinc-dust (Chichester Bell, *B.* 18, 877).—4. By distilling ammonium saccharate (Bell a. Lapper, *B.* 10, 1962).—5. By heating di-chloro-maleic imide with  $\text{PCl}_5$  at  $200^\circ$ , and reducing the resulting perchloride  $\text{O}_2\text{Cl}_2\text{N}$  with zinc-dust and  $\text{HOAc}$  (Ciamician a. Silber, *B.* 17, 554; 19, 3027). The dichloro-maleic imide may be got from succinimide and  $\text{PCl}_5$ .—6. By reducing tetra-iodo-pyrrole with zinc-dust and  $\text{KOH}$  (C. a. S.).—7. By heating albumen with  $\text{Ba}(\text{OH})_2$  at  $150^\circ$  (Schützenberger, *Bl.* [2] 25, 289).—8. By distilling pyromucic acid with ammonia-zinc chloride and  $\text{CaO}$  (Canzoneri a. Oliveri, *G.* 10, 487).—9. By passing di-ethyl-amine through a red-hot tube (Bell, *B.* 10, 1863). 10. By passing ethyl-allyl-amine over  $\text{PbO}$  at  $450^\circ$  (Koenigs, *B.* 12, 2344).—11. By distilling glutamic acid (Haitinger, *M.* 3, 238).

**Preparation.**—Bone oil is shaken with acids and distilled. The fraction  $98^\circ$ – $150^\circ$  is heated with  $\text{KOH}$  and distilled, and the portion  $125^\circ$ – $140^\circ$  heated with solid  $\text{KOH}$  with inverted condenser. The solid  $\text{C}_4\text{H}_7\text{NK}$  thus obtained is washed with ether and decomposed by water, and the pyrrole distilled with steam (Ciamician, *B.* 13, 70; 19, 173; *G.* 16, 336).

**Properties.**—Oil with fragrant odour, resembling chloroform. Tastes hot and pungent. *V. sol.* alcohol and ether, insol. dilute alkalis. Turns brown in air. Turns pine-wood soaked in  $\text{HCl}$  red. Dissolves in cold dilute acids, but on warming the solution pyrrole-red is formed as a bulky amorphous pp.  $\text{FeCl}_3$  added to its solution in  $\text{HCl}$  gives a green colour changing to black. Alcoholic  $\text{HgCl}_2$  gives a white pp. Isatin and  $\text{HOAc}$  or dilute  $\text{H}_2\text{SO}_4$  give a deep-blue pp. which forms a deep-blue solution in  $\text{HOAc}$  and  $\text{H}_2\text{SO}_4$  (V. Meyer, *B.* 16, 2974; Ciamician, *B.* 17, 142).

**Reactions.**—1.  $\text{HNO}_3$  forms oxalic acid.—2. **Potassium** acts very strongly, forming a colourless liquid, which solidifies on cooling to  $\text{C}_4\text{H}_7\text{NK}$ . Boiling with solid  $\text{KOH}$  gives the same body (Anderson, *A.* 105, 352). **Sodium** acts but slightly, forming  $\text{C}_4\text{H}_7\text{NNa}$  only at a very high temperature.  $\text{NaOHAq}$  has no action on pyrrole.—3.  $\text{HCl}$  passed into an ethereal solution ppts. crystalline  $(\text{C}_4\text{H}_7\text{N})\text{HCl}$ , whence ammonia liberates an unstable base (Dennstedt a. Zimmermann, *B.* 21, 1478).—4. **Hydroxylamine** forms  $\text{NH}_2$  and crystalline  $\text{C}_4\text{H}_7\text{N}_2\text{O}$  [ $175^\circ$ ]. Converted by adding  $\text{Na}$  to its boiling alcoholic solution into tetramethylene-diamine (Ciamician, *G.* 14, 156; *B.* 22, 1963). The compound  $\text{C}_4\text{H}_7\text{N}_2\text{O}$ , when heated with phenyl-hydrazine, yields  $\text{C}_8\text{H}_9\text{N}_3$ , which crystallises from alcohol in plates [ $125^\circ$ ].—5. By a dilute solution of sodium hypochlorite (15 pts. of active chlorine in 1,000 pts. of water to 10 pts. of pyrrol) it is converted into di-chloro-maleic acid and chlorinated pyrroles. On the other hand, a concentrated solution of sodium hypochlorite (45 pts. of active chlorine in 500 pts. of water to 10 pts. of pyrrole) yields dichloro-acetic acid. An alkaline solution of bromine yields dibromomaleimide. Iodine in presence of alkalis yields tetra-iodo-pyrrol (Ciamician a. Silber, *B.* 17, 1743; 18, 1763).—6. Potassium pyrrole heated with ethyl iodide yields *v*-ethyl-pyrrole, di-ethyl-pyrrole  $\text{C}_4\text{H}_5\text{Et}_2\text{NEt}$ , and probably also  $\text{C}_4\text{H}_5\text{Et}_3\text{NEt}$ . Potassium pyrrole and benzyl-chloride yield

*v*-benzyl-pyrrole ( $247^\circ$ ) (Ciamician, *B.* 22, 659; *G.* 17, 185).—7. Pyrrole (50 g.), boiled with *paraldehyde* (50 g.) and  $\text{ZnCl}_2$  (12 g.), forms oily ethyl-pyrrole  $\text{C}_5\text{H}_7\text{N}$  ( $164^\circ$ ) (Dennstedt a. Zimmermann, *B.* 19, 2139).—8. Pyrrole (1 pt.), *acetone* (10 pts.) and a drop of  $\text{HCl}$  give  $\text{C}_{11}\text{H}_{13}\text{N}_2$  [ $291^\circ$ ], whence alcoholic  $\text{AgNO}_3$  forms  $(\text{C}_{11}\text{H}_{13}\text{N}_2)\text{AgNO}_3$ , crystallising in needles (Baeyer, *B.* 19, 2184). The compound  $\text{C}_{11}\text{H}_{13}\text{N}_2$  yields, on distillation,  $\text{C}_{10}\text{H}_{11}\text{N}$  ( $275^\circ$ – $285^\circ$ ), which is probably mesityl-pyrrole, and whence  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  form *v*-acetyl-pyrrole. The compound  $\text{C}_{11}\text{H}_{13}\text{N}_2$ , examined by Raoult's method, appears to have the formula  $\text{C}_{10}\text{H}_{11}\text{N}_2$ . On heating pyrrole with *acetone* and  $\text{ZnCl}_2$ , isopropyl-pyrrole ( $174^\circ$ ) is formed. Among the products of the action of *acetone* on pyrrole there is also a yellow oil  $\text{C}_{12}\text{H}_{13}\text{N}$  (?) ( $300^\circ$ – $305^\circ$ ), which soon blackens in air. This oil forms an acetyl derivative [above  $360^\circ$ ], and is reduced by tin and alcoholic  $\text{HCl}$  to  $\text{C}_{11}\text{H}_{13}\text{N}$  ( $274^\circ$ ), which yields  $\text{B}^+\text{HCl}$  [ $228^\circ$ ] and  $\text{B}^+\text{HSnCl}_2$  [ $170^\circ$ ] (Dennstedt a. Zimmermann, *B.* 20, 850, 2449; 23, 1870).—9. **Di-ethyl ketone**,  $\text{MeOH}$ , and  $\text{HCl}$  give  $\text{C}_{18}\text{H}_{22}\text{N}_2$  [ $210^\circ$ ], which yields  $\text{B}^+\text{AgNO}_3$ , crystallising in needles (Dennstedt a. Zimmermann, *B.* 20, 2455).—10. **Chloroform** converts potassium pyrrole into ( $\beta$ )-chloro-pyridine. **Bromoform** acts in like manner, giving bromo-pyridine.  $\text{CH}_2\text{Cl}_2$  has no action, but  $\text{CCl}_4$  forms chloro-pyridine, while benzylidene chloride yields ( $\beta$ )-phenyl-pyridine (Ciamician, *B.* 14, 1160; 15, 1172; 20, 191; *G.* 16, 140).—11. Readily combines with diazo-compounds, forming azo- and disazo-bodies, but no compounds analogous to the diazoamides. Their constitution is probably  $\text{NH} \begin{smallmatrix} \text{C}(\text{N},\text{X})\text{:CH} \\ \text{CH}=\text{CH} \end{smallmatrix}$  and  $\text{NH} \begin{smallmatrix} \text{C}(\text{N},\text{X})\text{:CH} \\ \text{C}(\text{N},\text{X})\text{:CH} \end{smallmatrix}$  (O. Fischer a. Hepp, *B.* 19, 2251).—12. Pyrrole (5 g.) added to a lukewarm solution of *alloxan* (11 g.) in water (300 c.c.) forms colourless crystals of  $\text{C}_6\text{H}_7\text{N}_3\text{O}_4$  or  $\text{NH}_2\text{CO.NH.CO.CO.CO.C}_4\text{H}_7\text{NH}$ , sl. sol. hot alcohol, nearly insol. water and ether, and yielding  $\text{Ag}_2\text{A}'$ . Pyrrole-alloxan is converted by caustic potash solution into  $\text{C}_6\text{H}_7\text{N}_3\text{O}_4$  or  $\text{NH}_2\text{CO.CO.CO.CO.C}_4\text{H}_7\text{NH}$ , which crystallises in white plates, *v. sol.* warm alcohol, and yields  $\text{AgA}'$  and crystalline  $\text{MeA}'$  (Ciamician, *B.* 17, 106, 1711; 19, 1708; *G.* 16, 198, 857).—13. Pyrrole and  $\text{MeOH}$  distilled over zinc-dust yield ( $\alpha$ )- and ( $\beta$ )-methyl-pyrrole, di-methyl-pyrrole, and di-methyl-dipyrrole (Dennstedt, *B.* 24, 2559).—14. **Acetyl chloride**, acting on potassium-pyrrole, forms *v*-acetyl-pyrrole and pyrrol methyl ketone (pseudo-acetyl-pyrrole), which may be separated by steam-distillation.  $\text{Ac}_2\text{O}$  at  $800^\circ$  forms pyrrole di-methyl diketone (Ciamician a. Silber, *G.* 15, 193).—15. **Propionic anhydride** and **sodium propionate** form, on boiling, *v*-propionyl-pyrrole, pyrrol ethyl ketone, and pyrrole di-ethyl diketone (Dennstedt a. Zimmermann, *B.* 20, 1760).—16.  $\text{Bz}_2\text{O}$  and  $\text{NaOBz}$  at  $220^\circ$  form pyrrol phenyl ketone (pseudo-benzoyl-pyrrole). 17.  $\text{COCl}_2$  in benzene, added to  $\text{C}_4\text{H}_7\text{NK}$  in ether, forms  $\text{CO}(\text{C}_4\text{H}_7)_2$ , separating from ligroin in monoclinic crystals [ $63^\circ$ ] ( $238^\circ$ ) (Ciamician a. Magnaghi, *B.* 18, 415).—18. **Phthalic anhydride** and  $\text{HOAc}$  at  $185^\circ$  form  $\text{C}_{12}\text{H}_9\text{NO}_2$  [ $241^\circ$ ], converted by  $\text{Br}$  into  $\text{C}_{12}\text{H}_7\text{BrNO}_2$  [ $199^\circ$ ], and by boiling  $\text{KOH}$  into  $\text{C}_{12}\text{H}_7\text{NO}_2$  [ $174^\circ$ – $184^\circ$ ], which yields  $\text{MeA}'$  [ $105^\circ$ ] (Ciamician, *B.* 17, 2957;

Anderlini, *B.* 21, 2869). The compound  $C_4H_5NO_2$  is reduced by water and Na to  $C_4H_5N \cdot C \begin{smallmatrix} O \\ \diagup \end{smallmatrix} \begin{smallmatrix} H \\ \diagdown \end{smallmatrix} CH.OH$  [118°] (Ciamician, *B.* 19, 2206; 21, 1554).

Salts.— $C_4H_5NK$ . Solid, absorbing  $CO_2$  at 200°, forming pyrrole ( $\beta$ )-carboxylic acid.— $B'2HgCl_2$ : crystalline powder, insol. water, sl. sol. cold alcohol.— $B'3CdCl_2$ .— $B'ICl$ : black pp. (Dittmar, *B.* 18, 1612).—Picrate: [c. 71°]; unstable (Hooker, *B.* 21, 3299).

**Acetyl derivative**  $C_4H_5NAC$ . (182° i.v.). Formed by the action of  $AcCl$  on potassium-pyrrole suspended in ether, and also as a by-product in the preparation of pyrrol methyl ketone by heating pyrrole with  $Ac_2N$  and  $NaOAc$  (Ciamician, *B.* 16, 2348; 18, 881). Oil, volatile with steam, saponified by hot  $KOH$  aq. Reddons acidified pine-wood. Gives a pp. with aqueous  $HgCl_2$ .

**Propionyl derivative**  $C_4H_5N.COEt$ . (193°) (Dennstedt a. Zimmermann, *B.* 20, 1760).

**Dihydride**  $C_4H_5N$ . **Pyrroline**. (90° i.v.). Formed by reducing pyrrole with zinc-dust and  $HOAc$  (Ciamician a. Dennstedt, *B.* 16, 1536; 22, 2512; *G.* 15, 481). Hygroscopic liquid, v. sol. water. Yields a nitrosamine  $C_4H_5N(NO)$  [38°]. Absorbs  $CO_2$  from the air.— $B'HCl$  [174°]. Plat prisms, v. sol. hot alcohol.— $B'H_2PtCl_4$ : triclinic crystals.— $B'IAuCl_4$  [152°].— $B'C_4H_5N_2O_2$ . [156°]. Yellow crystals (from water). **Benzoyl derivative**  $C_4H_5N.Bz$ . (160° at 2 mm.). Syrup, formed from the hydrochloride and  $BzCl$  at 110°. V. sol. alcohol.

**Tetrahydride**  $C_4H_8N$ . **Pyrrolidine**. (88.5°). S.G. 25° 8520. Formed by reducing the dihydride by  $HIAq$  at P at 250° (Ciamician a. Magnaghi, *G.* 15, 483; *B.* 18, 2079). Formed also, together with tetra-methylene-diamine, by the action of Na on ethylene cyanide or succinimide in alcohol, and by distilling tetramethylene-diamine hydrochloride (Ladenburg, *B.* 19, 782; 20, 442, 2215; Petersen, *B.* 21, 290). Formed from chlorobutylamine hydrochloride and  $KOH$  aq (Gabriel, *B.* 24, 3234). Liquid, with pungent ammoniacal odour. Yields a liquid nitrosamine (214°), v. sol. water.— $B'H_2PtCl_6$ . [200°]. Prisms.— $B'HAuCl_4$ . [206°].— $B'C_4H_5N_2O_2$ . [112°].— $B'H_2BiI_6$ .— $B'H_2CdI_2$ . [219°]. Needles.

**Pyrrole red**  $C_{12}H_{11}N_2O$ ? Formed by boiling pyrrole or its carboxylic acid with dilute  $H_2SO_4$  or  $HCl$  (Anderson, *A.* 105, 357; Schwanert, *A.* 116, 280). Reddish-brown flakes, insol. water, ether, acids, and alkalis, sl. sol. alcohol. Yields pyrrole on distillation.

**Homopyrrole v. METHYL-PYRROLE.**

**References.**—BROMO-, CHLORO-, IODO, NITRO-, and OXY-AMIDO-PYRROLE.

**PYRROLE - AZO- v. AZO-COMPOUNDS and DISAZO-COMPOUNDS.**

**PYRROL-CARBO-KETONIC ACID v. PYRROL-GLYOXYLIC ACID.**

**PYRROLE (a)-CARBOXYLIC ACID**  $C_4H_5NO_2$ , i.e.  $C_4H_5(CO_2H)NH$ . **Carboxypyrrolic acid**. [191°].

**Formation.**—1. By the action of boiling baryta on its amide, which is got by distilling ammonium mucate (Malaguti, *A.* 15, 179; Schwanert, *A.* 116, 270; Ciamician, *B.* 17, 111).—2. By boiling pyrocoll with  $KOH$  aq (Weidel a. Ciamician, *M.* 1, 285).—3. By fusing potassium (a)-methyl-pyrrole with potash (Ciamician, *B.*

14, 1054; *G.* 11, 228).—4. By heating pyrrole with ammonium carbonate and water at 140° (Ciamician a. Silber, *B.* 17, 1150; *G.* 14, 162).—5. By heating pyrrole with alcoholic potash and  $CCl_4$  (Ciamician a. Silber, *B.* 17, 1437).—6. By the action of  $CO_2$  on potassium pyrrole at a high temperature (C. a. S.).

**Properties.**—Prisms (from water), sol. water and alcohol. Decomposed by heat into  $CO_2$  and pyrrole.  $HCl$  aq forms, on warming,  $CO_2$ , pyrrole red, and  $NH_4Aq$ .

Salts.— $NH_4A'$ : m. sol. water.— $CaA'$ : scales.— $BaA'$  (dried at 100°): plates, sol. water and alcohol.— $PbA'$ : nacreous scales, v. sol. water.— $AgA'$ : small needles, sl. sol. water.

**Methyl ether**  $MeA'$ . [173°]. Prisms.

**Ethyl ether**  $EtA'$ . [39°] [231°].

**Amide**  $C_4H_5(CONH_2)N$ . [173°]. Laminæ, v. sol. alcohol and ether, m. sol. water.

**Acetyl derivative**  $C_4H_5N.CO.OAc$ . [75°]. Formed from the  $Ag$  salt and  $AcCl$ . Scales, readily decomposed by water into acetic acid and pyrrole carboxylic acid. At 75° it decomposes into  $HOAc$  and pyrocoll.

**Pyrrole ( $\beta$ )-carboxylic acid**  $C_4H_5(CO_2H)NH$ . [162°]. Formed by fusing potassium ( $\beta$ )-methyl-pyrrole with potash (Ciamician, *B.* 14, 1054). Needles, partially decomposed by boiling water into  $CO_2$  and pyrrole. The lead salt is sl. sol. water.— $BaA'$ : needles. A pyrrole carboxylic acid [166°], got by potash-fusion from isopropyl-pyrrole, and yielding a methyl ether [129°] (Dennstedt a. Zimmermann, *B.* 20, 855), is probably identical with the ( $\beta$ )-acid.

**Pyrrole  $\nu$ -carboxylic acid**

**Ethyl ether**  $C_4H_5N.CO_2Et$ . **Tetrol-urethane**. (180°). Formed from potassium-pyrrole and  $ClCO_2Et$  in ether (Ciamician a. Dennstedt, *G.* 12, 84). Oil.

**Amide**  $C_4H_5N.CONH_2$ . [167°]. Formed from the ether and  $NH_3$ .

**Nitrile**  $C_4H_5N.CN$ . **Tetrol cyanuramide**. [210°]. Got by passing  $CyCl$  into potassium-pyrrole in ether (Ciamician a. Dennstedt, *G.* 13, 102). Needles, insol. water, sol. hot alcohol. Boiling alcoholic potash forms pyrrole,  $CO_2$ , and  $NH_3$ .

**Pyrrole dicarboxylic acid**  $C_4H_5NO_4$ , i.e.  $C_4H_5(CO_2H)_2NH$ . Formed by oxidising pyrrole dimethyl diketone, and fusing the product with potash (Ciamician a. Silber, *G.* 16, 377; *B.* 19, 1958; 20, 2601). Needles (from dilute alcohol), sol. ether and hot water. Blackens at 260°, giving pyrrole and  $CO_2$ .  $FeCl_3$  gives a brown pp. The  $Ba$  salt crystallises in needles. The  $Ag$  salt is a curdy pp.

**Mono-methyl ether**  $MeHA'$ . [243°].

**Di-methyl ether**  $Me_2A'$ . [132°].

**Di-ethyl ether**  $Et_2A'$ . [82°].

**References.**—BROMO-, CHLORO-, and NITRO-PYRROLE CARBOXYLIC ACIDS.

**PYRROLINE.** A name used both for PYRROLE and PYRROLE DIHYDRIDE.

**PYRROLYLENE v. BUTINENE.**

**PYRROLYLENE TETRABROMIDE v. TETRABROMO-BUTANE.**

**PYRRONE v. DI-PYRROL-KETONE.**

**PYRROYL-FORMIC ACID v. PYRROL-GLYOXYLIC ACID.**

**PYRROYL - PYRROL**  $C_4H_5N.CO.C_4H_5NH$  [63°]. Formed, together with di-pyrrol-ketone

**CO(C<sub>6</sub>H<sub>5</sub>NH)**, by intramolecular transformation of carbonyl-pyrrole by heating it to 250° for a few hours (Ciamician a. Magnaghi, *B.* 18, 1829). White silky plates. Not volatile with steam. By heating with aqueous KOH it is split up into pyrrole and pyrrole-(a)-carboxylic acid.

**PYRROYL-PYRUVIC ACID.** *Ethyl ether* C<sub>6</sub>H<sub>5</sub>NH.CO.CH<sub>2</sub>.CO.CO<sub>2</sub>Et. [123°]. Formed by the action of NaOEt and oxalic ether on pyrrol methyl ketone (Angeli, *B.* 23, 1794, 2155). Yellowish plates, v. sol. alcohol, sl. sol. water. Decomposed by alkalis, even in the cold, into oxalic acid and pyrrol methyl ketone. Hydroxylamine forms C<sub>10</sub>H<sub>10</sub>N<sub>2</sub>O<sub>2</sub> [124°], which on saponification yields the acid CH<sub>2</sub>.C.CO.CH<sub>2</sub>.C<sub>6</sub>H<sub>5</sub>NH.N : C.CO<sub>2</sub>H [179°], crystallising in white needles. Aniline (2 pts.) in HOAc forms C<sub>6</sub>H<sub>5</sub>NH.CO.CH<sub>2</sub>.C(NPh).CO<sub>2</sub>Et [115°]. Phenyl-hydrazine forms C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>2</sub> [168°] which is the ether of an acid [215°].

*Anhydride* CH<sub>2</sub>.C.CO.CH<sub>2</sub>.C<sub>6</sub>H<sub>5</sub>NH.N : C.CO<sub>2</sub>H. [250°]. Formed by adding HCl to the mother-liquor from which the ether has separated (Angeli, *B.* 23, 1795). Yellow needles (from benzene), v. sol. alcohol. *o*-Phenylene-diamine forms C<sub>12</sub>H<sub>8</sub>N<sub>2</sub>O, a reddish-yellow crystalline powder forming a bluish-green solution in H<sub>2</sub>SO<sub>4</sub> and yielding a benzoyl derivative [c. 166°]. Aniline forms C<sub>6</sub>H<sub>5</sub>NH.CO.CH<sub>2</sub>.C.CO<sub>2</sub>NPh [218°], whence cold KOH aq forms an acid C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>2</sub> [179°].

**PYRRYLENE DIETHYL DIKETONE** C<sub>6</sub>H<sub>5</sub>NH(COEt)<sub>2</sub>. [117°]. Formed by heating pyrrole with propionic anhydride at 260° (Dennstedt a. Zimmermann, *B.* 20, 1761). Plates.

**PYRRYLENE DI-METHYL DIKETONE** C<sub>6</sub>H<sub>5</sub>NO<sub>2</sub> i.e. NH<Cac:CH  
Cac:CH' [162°]. Formed by heating pyrrole, pyrrol methyl ketone, or acetyl-pyrrole with Ac<sub>2</sub>O at 250° (Ciamician, *B.* 17, 432, 2953; 18, 881, 1466; 19, 1957; 20, 2595). Needles, sol. hot water and hot KOH aq. May be sublimed. Yields a nitro-derivative [149°] and a di-bromo-derivative [172°].—AgA'.

**PYRRYLENE DISTYRYL DIKETONE** (C<sub>6</sub>H<sub>5</sub>.CH:CH.CO).C<sub>6</sub>H<sub>5</sub>NH. [240°]. Formed by heating pyrrole dimethyl diketone with benzoic aldehyde and KOH aq (Ciamician a. Dennstedt, *B.* 17, 2953). Crystals (from HOAc), sl. sol. alcohol. Forms a violet solution in H<sub>2</sub>SO<sub>4</sub>.

**PYRRYL ETHYL KETONE** C<sub>6</sub>H<sub>5</sub>NO i.e. C<sub>6</sub>H<sub>5</sub>.CO.C<sub>6</sub>H<sub>5</sub>NH. [52°]. (224°). Formed by boiling pyrrole with propionic anhydride and sodium propionate (Dennstedt a. Zimmermann, *B.* 20, 1761). Colourless needles.—AgA': pp.

**PYRRYL-GLYOXYLIC ACID** C<sub>6</sub>H<sub>5</sub>NO<sub>2</sub> aq i.e. C<sub>6</sub>H<sub>5</sub>NH.CO.CO<sub>2</sub>H aq or C<sub>6</sub>H<sub>5</sub>NH.C(OH)<sub>2</sub>.CO<sub>2</sub>H. Formed by oxidation of pyrrol methyl ketone by KMnO<sub>4</sub> (Ciamician a. Dennstedt, *B.* 16, 2350; 17, 2949). Crystallises from benzene in yellow needles (of C<sub>6</sub>H<sub>5</sub>NO<sub>2</sub>) melting at 76°, v. sol. hot water. After drying over sulphuric acid the acid (C<sub>6</sub>H<sub>5</sub>NO<sub>2</sub>) decomposes at 114°. The aqueous solution gives a red colour with FeCl<sub>3</sub>. On heating with HCl aq it gives a crimson colour turned yellowish-green by alkalis.—AgA': colourless needles, sol. hot water.

*Methyl ether* MeA'. [72°]. (285°). Monoclinic crystals, sl. sol. water.

**Carboxy-pyrrol-glyoxylic acid** CO<sub>2</sub>H.C<sub>6</sub>H<sub>5</sub>NH.CO.CO<sub>2</sub>H. Formed by oxidation of pyrrole dimethyl diketone (Ciamician a. Silber, *B.* 19, 1412, 1961). Crystalline, v. sol. hot water.—AgA': canary-yellow pp.

*Methyl ether* MeA'. [145°].  
**DI-PYRRYL KETONE** CO(C<sub>6</sub>H<sub>5</sub>NH)<sub>2</sub>. [180°]. Formed, together with (C<sub>6</sub>H<sub>5</sub>N)<sub>2</sub>CO, by the action of COCl<sub>2</sub> on C<sub>6</sub>H<sub>5</sub>NK. Formed also, together with pyrrol-pyrrole, by heating (C<sub>6</sub>H<sub>5</sub>N)<sub>2</sub>CO at 250° for a few hours (Ciamician a. Magnaghi, *B.* 18, 414, 1829). Trimetric crystals; a:b:c = 2.531:1:2.901. V. sol. alcohol, ether, and benzene, nearly insol. water.—AgA': yellow pp.

**PYRRYL METHYL KETONE** C<sub>6</sub>H<sub>5</sub>NO i.e. CH<sub>2</sub>.CO.C<sub>6</sub>H<sub>5</sub>NH or NH<Cac:CH  
Cac:CH' *Pseudo-acetyl-pyrrole*. [90°]. (220° uncer.). V.D. 3.8 (calc. 3.8). Formed by boiling pyrrole with Ac<sub>2</sub>O and NaOAc (R. Schiff, *B.* 10, 1501; Ciamician a. Dennstedt, *B.* 16, 2348; 17, 432, 2944; 18, 1456; 20, 2605; G. 15, 175). Formed also by heating pyrrole with Ac<sub>2</sub>O and ZnCl<sub>2</sub> (Dennstedt a. Zimmermann, *B.* 19, 2204), and by heating CH<sub>2</sub>.CO.C<sub>6</sub>H<sub>5</sub>N.CO<sub>2</sub>K with K<sub>2</sub>CO<sub>3</sub> at 290° (Ciamician a. Silber, *B.* 19, 1963). Long monoclinic needles, sol. hot water, v. sol. aqueous alkalis, sparingly volatile with steam. Not converted into pyrrole and KOAc by potash.

*Reactions*.—1. Yields pyrrol-glyoxylic acid when oxidised by KMnO<sub>4</sub>.—2. *Benzoic aldehyde* and dilute KOH form pyrrol styryl ketone.—3. Water and sodium-amalgam reduce it to crystalline pyrrol methyl pinacone C<sub>6</sub>H<sub>5</sub>N<sub>2</sub>O<sub>2</sub> [120°] and pyrrol-methyl-carbinol CH<sub>2</sub>.CH(OH).C<sub>6</sub>H<sub>5</sub>NH an oil (290°–300°). Pyrrol-methyl-pinacone C<sub>6</sub>H<sub>5</sub>N.CMe(OH).CMe(OH).C<sub>6</sub>H<sub>5</sub>N crystallises in prisms (containing 2aq) melting at 98° when hydrated.—4. *Oxalic ether* and NaOEt form pyrrol-pyruvic ether (Angeli, *B.* 23, 1357, 1794). 5. Cold fuming H<sub>2</sub>SO<sub>4</sub> yields an unstable sulphonic acid, which forms a crystalline K salt.

*Salt*.—C<sub>6</sub>H<sub>5</sub>AcNag. Crystalline pp.  
*Oxim* CH<sub>2</sub>.C(OH).C<sub>6</sub>H<sub>5</sub>NH. [146°]. Needles.

*Phenyl-hydrazide* C<sub>6</sub>H<sub>5</sub>.C(NPh).C<sub>6</sub>H<sub>5</sub>NH. [147°]. White powder.

*References*.—AMIDO-, BROMO-, BROMO-NITRO-, and NITRO- PYRRYL METHYL KETONE.

**PYRRYL METHYL KETONE CARBOXYLIC ACID** C<sub>6</sub>H<sub>5</sub>NO<sub>2</sub> i.e. CH<sub>2</sub>.CO.C<sub>6</sub>H<sub>5</sub>N.CO<sub>2</sub>H. [186°]. Formed by saponification of its methyl ether, obtained by heating methyl pyrrole (a)-carboxylate with Ac<sub>2</sub>O at 260° (Ciamician a. Silber, *G.* 14, 169; *B.* 17, 1155). Leaflets, sol. water, alcohol, and ether. FeCl<sub>3</sub> gives a brown pp.—CaA', 7aq: triclinic prisms.—\*PbA'<sub>2</sub>: needles.—AgA': powder, sl. sol. water.

*Methyl ether* MeA'. [113°]. Gives with ammoniacal AgNO<sub>3</sub> a pp. C<sub>6</sub>H<sub>5</sub>AgNO<sub>2</sub>.

**PYRRYL PHENYL KETONE** C<sub>6</sub>H<sub>5</sub>NO i.e. C<sub>6</sub>H<sub>5</sub>.CO.C<sub>6</sub>H<sub>5</sub>NH. [78°]. Formed by heating pyrrole with benzoic anhydride and dry NaOBz at 200°–240° (Ciamician a. Dennstedt, *B.* 17, 432, 2955). Needles, v. sol. alcohol, sl. sol. hot water.—C<sub>6</sub>H<sub>5</sub>AgNO.

**PYRRYL STYRYL KETONE** C<sub>6</sub>H<sub>5</sub>NO i.e. C<sub>6</sub>H<sub>5</sub>.CH.CH.CO.C<sub>6</sub>H<sub>5</sub>NH. [142°]. Formed by boiling pyrrol methyl ketone with C<sub>6</sub>H<sub>5</sub>CHO and KOH aq (Ciamician a. Dennstedt, *B.* 17, 2947). Yellow needles, sl. sol. alcohol, insol. water.—C<sub>6</sub>H<sub>5</sub>ONAg: yellow needles, insol. NH<sub>4</sub>Aq.

**PYRUVIC ACID**  $\text{C}_2\text{H}_3\text{O}_2$ , i.e.  $\text{CH}_3\text{CO}_2\text{CO}_2\text{H}$ .  
*Pyruvic acid. Di-oxy-propionic acid.* Mol. w. 88. [9°]. (c. 165°). S.G.  $\frac{4}{5}$  1.2752;  $\frac{16}{17}$  1.2700. M.M. 8.557 (Perkin, C. J. 61, 836).

**Formation.**—1. By distilling racemic or tartaric acid (Berzelius, A. 18, 61; Völckel, A. 89, 65; Wislicenus, A. 126, 225).—2. By gradually heating tartaric acid with  $\text{HClAq}$  in sealed tubes to 180° (Geuther a. Riemann, Z. [2] 5, 818).—3. By heating tartaric acid with conc.  $\text{H}_2\text{SO}_4$  at 40°–50° (Bouchardat, C. R. 89, 99).—4. By heating silver di- $\alpha$ -chloro-propionate with water (Beckurts a. Otto, B. 10, 265; 18, 227).—5. By distilling glyceric acid (Moldenhauer, A. 131, 338; Böttinger, A. 196, 92).—6. By boiling acetyl cyanide with dilute  $\text{HCl}$  (Claisen a. Shadwell, B. 11, 1563).—7. By oxidation of a cold aqueous solution of calcium lactate by  $\text{KMnO}_4$  (Beilstein a. Wiegand, B. 17, 840).

**Preparation.**—1. Tartaric acid (3 lbs.) is distilled from a glass retort (30 lbs. capacity). The distillation takes three hours. A fresh quantity of tartaric acid is then added and the operation repeated. The distillate is fractionally distilled (Clewing, J. pr. [2] 17, 243).—2. Dried, and finely powdered, tartaric acid is mixed with an equal weight of sand and distilled (Seissl, A. 249, 297). 8. Tartaric acid is distilled with  $\text{KHSO}_4$ , the yield being 50 to 60 p.c. (Erlenmeyer, B. 14, 321).

**Properties.**—Liquid, smelling like acetic acid, v. e. sol. water, alcohol, and ether. Colourless crystals below 9° (Simon, Bl. [3] 9, 111). Partially decomposed on distillation. Reduces ammoniacal  $\text{AgNO}_3$ , forming a mirror, and yielding  $\text{CO}_2$  and acetic acid. Coloured cherry-red by alkaline sodium-nitrosobisulphite, the colour being discharged by  $\text{HOAc}$  (Von Bitto, A. 267, 377). Readily ppd. by phenyl-hydrazine. Forms an oxim.

**Reactions.**—1. Dilute  $\text{H}_2\text{SO}_4$  at 150° splits it up into aldehyde and  $\text{CO}_2$  (B. a. W.).—2. By long heating at 170° it is converted into  $\text{CO}_2$  and acetic, pyrotartaric, uvic, and citraconic acids (Böttinger, B. 9, 670, 837, 1823).—3.  $\text{HClAq}$  at 100° forms  $\text{CO}_2$  and pyrotartaric acids (De Clermont, B. 6, 72).—4. Boiling with  $\text{Ag}_2\text{O}$  yields  $\text{CO}_2$  and acetic acid.—5. Reduced to lactic acid by sodium-amalgam, and by  $\text{Zn}$  and  $\text{H}_2\text{SO}_4$ .—6.  $\text{HI}$  reduces it to propionic acid.—7.  $\text{Zinc}$  when added to its alcoholic solution forms  $\text{CO}_2$ ,  $\text{H.CMe(OH).CMe(OH).CO}_2\text{H}$  (Böttinger, B. 9, 1064).—8.  $\text{PCl}_5$  forms di- $\alpha$ -chloro-propionic acid (Klimenko, B. 3, 465; Beckurts a. Otto, B. 11, 386).—9. Dry bromine at 0° forms crystalline di-bromo-lactic acid (?). Br and water give di-bromo-pyruvic acid (Wislicenus, A. 148, 208; Wichelhaus, A. 152, 265).—10. Oxidised by chromic acid mixture to  $\text{CO}_2$  and acetic acid.—11.  $\text{HNO}_3$  forms oxalic acid and  $\text{CO}_2$ .—12. Boiling baryta-water forms uvitic, uvic, pyrotartaric, oxalic, and acetic acids and  $\text{CO}_2$  (Finckh, A. 122, 182; Böttinger, B. 8, 957; A. 172, 241, 253; 188, 813; 208, 129). Baryta-water added to a cold solution of pyruvic acid ppts. barium hydrurate  $\text{BaC}_2\text{H}_3\text{O}_6$ , or the basic salt  $\text{Ba}_2\text{H}_2(\text{C}_2\text{H}_3\text{O}_6)_3$ . Hydruric acid is a syrup.—13. On heating with excess of *quicklime* it yields a little aldehyde (Hanriot, C. R. 101, 1156; Bl. [2] 45, 81).—14.  $\text{HCN}$  followed by  $\text{HCl}$  forms lactic acid.  $\text{KCN}$  followed by  $\text{HCl}$  yields

$\text{CH}_2\text{C(OH)(CN).CO}_2\text{H}$  v. **CYANO-OXY-PROPIONIC ACID**. On warming pyruvic acid with  $\text{HCN}$  under pressure the product is  $\text{CMe(NH}_2\text{)(CO}_2\text{H)}$ , crystallising in unstable prisms (Körner a. Menozzi, G. 17, 104).—15. Alcoholic ammonia forms methyl-pyridine dicarboxylic acid.—16. Aniline added to an ethereal solution forms  $\text{C}_6\text{H}_5\text{NO}_2$ , i.e.  $\text{CH}_2\text{C(NPh).CO}_2\text{H}$  [122°] (Böttinger, B. 10, 818). Aniline alone forms, on heating,  $\text{C}_6\text{H}_5\text{N}_2\text{O}$ , crystallising from dilute alcohol in needles [195°], while *p*-toluidine gives  $\text{C}_6\text{H}_4\text{N}_2\text{O}$  [238°] (Lazarus, B. 17, 998). Aniline and fur-

furaldehyde form  $\text{C}_6\text{H}_4\text{C(OH):CHC}_2\text{H}_3\text{O}_2$ , crystallising in greenish-yellow needles [210°–215°] (Doebner, A. 242, 285). Tetra-amido-anisole forms the quinoxaline  $\text{C}_6\text{H(OMe)(N}_2\text{C}_2\text{H}_3\text{O}_2)_4$  as orange-yellow flakes, v. sol. alkalis (Nietzki a. Kutenacker, B. 25, 284).—17.  $\text{H}_2\text{S}$  passed into water containing the Ag salt forms thiolaetic acid (Böttinger, B. 9, 404; Lovén, J. pr. [2] 29, 376).—18.  $\text{PH}_3$  and  $\text{HCl}$  passed into an ethereal solution form 'phosphorotrihydripyruvic' acid  $\text{C}_2\text{H}_5\text{PO}_3$ , crystallising in needles, insol. alcohol and ether, and forming with phenyl-hydrazine the compounds  $\text{C}_6\text{H}_5\text{PO}_3\text{PhN}_2\text{H}_2$  [132°] and  $\text{C}_6\text{H}_5\text{N}_2\text{O}_2$  (?) [162°]. The acid  $\text{C}_2\text{H}_5\text{PO}_3$  is converted by aniline into  $\text{C}_6\text{H}_5\text{N}_2\text{PO}_3$  [158°], whence phenyl-hydrazine forms  $\text{C}_6\text{H}_5\text{N}_2\text{O}_2$  [169°]. Toluene-diamine converts  $\text{C}_2\text{H}_5\text{PO}_3$  into  $\text{C}_6\text{H}_5\text{PO}_3\text{C}_6\text{H}_4\text{N}_2$  [178°] (Messinger a. Engels, B. 21, 334, 2919).—19. Pyruvic acid (50 g.) heated with dry sodium succinate (92 g.) and  $\text{Ac}_2\text{O}$  (58 g.) at 110° forms di-methyl-maleic anhydride (pyrocinchonic anhydride) (Fittig a. Parker, A. 267, 204). Pyruvic acid (30 g.) heated with dry sodium succinate (55 g.) at 110° forms uvic (pyrotartaric) acid.—20. Pyruvic acid (30 g.) heated with sodium pyrotartrate (60 g.) and  $\text{Ac}_2\text{O}$  (36 g.) at 140° forms methyl-ethyl-maleic anhydride (F. a. P.).—21. Benzoinitrile and cold  $\text{H}_2\text{SO}_4$  form an acid  $\text{C}_6\text{H}_5\text{N}_2\text{O}_2$ , crystallising in tables [172°], insol. water, v. sol. acetone (Böttinger, B. 14, 1599).—22. Phenyl-acetonitrile and  $\text{H}_2\text{SO}_4$  form, in like manner,  $\text{C}_6\text{H}_5\text{N}_2\text{O}_2$  [145°] (B.).—23. By heating with aldehydes  $\text{RCHO}$  and baryta-water it is converted into *s*-alkyl-isophthalic acids of the form  $\text{C}_6\text{H}_4\text{R(CO}_2\text{H)}_2$  (Doebner, B. 23, 2378).—24. Benzoin aldehyde and aniline in ether form, in the cold,  $\text{C}_6\text{H}_5\text{N}_2\text{O}$  or  $\text{CHPh:CHC(NPh).CONHPh}$  [225°], insol. water, acids, and alkalis, sl. sol. alcohol and ether. Cumiric aldehyde and aniline give  $\text{C}_6\text{H}_5\text{N}_2\text{O}$  [216°] (Doebner a. Giescke, A. 242, 290; 249, 102). Benzoin aldehyde and *p*-toluidine form, in like manner,  $\text{C}_6\text{H}_4\text{N}_2\text{O}$  [205°].—25. Isobutyric aldehyde and aniline in alcoholic solution react forming  $\text{CHPr.CHC(NPh).CONHPh}$  (?) [222°] crystallising from  $\text{HOAc}$  in needles, while isovaleric aldehyde and aniline in ether give  $\text{C}_6\text{H}_5\text{N}_2\text{O}$  [160°] (Doebner, A. 242, 275). Isovaleric aldehyde in warm alcoholic solution forms the acid  $\text{C}_6\text{H}_5\text{NO}_2$ .—26. Thioglycolic acid gives rise to  $\text{CO}_2$ ,  $\text{H.CMe(OH).S.CH}_2\text{CO}_2\text{H}$  [110°] with evolution of heat; while  $\text{HCl}$  passed through a mixture of pyruvic and thioglycolic acids produces  $\text{CO}_2$ ,  $\text{H.CMe(S.CH}_2\text{CO}_2\text{H)}_2$  [162°] crystallising from ether (Bongartz, B. 19, 1933; 21, 484).—27. Phenyl mercaptan forms the compound  $\text{CH}_2\text{C(SPh)(OH).CO}_2\text{H}$ , while *p*-bromo-phenyl mercaptan forms  $\text{CH}_2\text{C(SC}_6\text{H}_4\text{Br)(OH).CO}_2\text{H}$

[114.5°] (Baumann, *B.* 18, 263).—28. *Ethylene mercaptan* forms a substance [96°] which crystallises from benzene as a fine powder, and may be condensed to  $\text{CH}_2\text{S} \cdot \text{CH}_2\text{S} > \text{CMe} \cdot \text{CO}_2\text{H}$  [102°], which

on oxidation gives ethylene ethyldiene disulphone [198°] (Fasbender, *B.* 21, 1473).—29. *Benzene* and  $\text{H}_2\text{SO}_4$  form  $\text{CH}_3\text{CPh} \cdot \text{CO}_2\text{H}$ , while phenol and  $\text{H}_2\text{SO}_4$  yield  $\text{C}_6\text{H}_5\text{O} \cdot \text{CMe} \cdot \text{CO}_2\text{H}$  (Böttger, *B.* 14, 1595; 16, 2071).—30. Distillation of the K salt with KOAc forms acetone and pyrotartaric acid (Wieland, *Z.* [2] 5, 254).—31. Pyruvic acid (1 pt.) heated with urea (2 pts.) at 100° forms pyruvil or 'pyruvic diureide'  $\text{C}_4\text{H}_5\text{N}_3\text{O}_3$ , which crystallises in tables, S. 10 at 100°, insol. alcohol and ether (Grimaux, *C. R.* 79, 526, 1304, 1478; 80, 53; *A. Ch.* [5] 11, 373). Pyruvil is decomposed by long heating at 160°, forming amorphous 'tetra-pyruvic tetraureide'  $\text{C}_{16}\text{H}_{18}\text{N}_8\text{O}_{16}$ , insol. water. Boiling dilute HClAq converts pyruvil into urea and 'dipyrvic triureide'  $\text{C}_6\text{H}_{12}\text{N}_6\text{O}_6$ , which crystallises from hot water in needles, S. 4 at 100°, decomposed by boiling alkalis into urea, pyruvic acid, and pyruvil. Boiling conc. HClAq converts pyruvil into urea and 'pyruvic ureide'

$\text{C}_4\text{H}_5\text{N}_3\text{O}_2$  or  $\text{CO} < \text{N} = \text{CMe} \cdot \text{NH} \cdot \text{CO}$ , a crystalline

powder, m. sol. hot water, insol. alcohol. Nitric acid converts pyruvil into nitro-pyruvic ureide  $\text{C}_4\text{H}_4(\text{NO}_2)_2\text{N}_2\text{O}_2$  [above 200°], which is decomposed by boiling bromine-water into parabanic acid and  $\text{CBr}_3 \cdot \text{NO}_2$ . Pyruvic acid heated with an equal weight of urea at 100° forms amorphous insoluble 'tripyrvic tetraureide'  $\text{C}_6\text{H}_6\text{N}_6\text{O}_6$  and dipyrvic triureide.—32. *Sodium hippurate* and  $\text{Ac}_2\text{O}$  at 100° form the dibasic acid  $\text{C}_{12}\text{H}_8\text{N}_4\text{O}_{10}$  [157°] (A. Hoffmann, *B.* 19, 2555).—33. A solution of *indoxyl* forms on adding conc. HCl the indogenide  $\text{C}_8\text{H}_7 < \text{CO} \cdot \text{NH} > \text{C} \cdot \text{CMe} \cdot \text{CO}_2\text{H}$  [197°],

crystallising in red needles forming a blue solution in  $\text{H}_2\text{SO}_4$  (Baeyer, *B.* 16, 2199).—34. *Glycerin* and  $\text{KH}_2\text{SO}_4$  form 'glycuvic acid,' or 'pyruvin,' which is also got by heating glycerin with glyceric acid at 120°, and by distilling glycerin with citric acid. Glycuvic acid is probably  $\text{CH}_3 \cdot \text{CO} \cdot \text{CO} \cdot \text{O} \cdot \text{CH}_2 \cdot \text{CH} < \text{O} \cdot \text{CH}_3$ . It is crystalline [82°] (241°), and yields pyruvic acid when boiled with baryta (Böttger, *B.* 10, 286; 14, 316; *A.* 263, 246; Jowanovitch, *M.* 6, 467; Erhardt, *M.* 6, 511; Schlagdenhauffen, *C. R.* 74, 672; De Clermont, *C. R.* 105, 520).

**Salts.**—The salts crystallise well, provided heat is avoided in their preparation; otherwise they become amorphous. The acid also is changed by evaporation of its aqueous solution into a non-volatile syrupy mass.—NaA': large prisms.—BaA': aq. scales.—BaA': 2aq. amorphous.—PbA': aq. crystalline pp.—ZnA': 3aq. white microcrystalline powder, sl. sol. water (Beckurts a. Otto, *B.* 18, 227).—CuA': aq.—AgA': scales, sl. sol. water.

**Combinations with bisulphites** (Clowing, *J. pr.* [2] 17, 241).—HA'NaHSO<sub>3</sub> aq. crystals.—NaA'NaHSO<sub>3</sub> aq.—NaA'NaHSO<sub>3</sub> 1½ aq.—HA'KHSO<sub>3</sub>: octahedra.—KA'KHSO<sub>3</sub> aq.—CaA'<sub>2</sub>Ca(HSO<sub>3</sub>)<sub>2</sub> 3aq.—(CaA')<sub>2</sub>(Ca(HSO<sub>3</sub>)<sub>2</sub>)<sub>2</sub> 24aq.—(CaA')<sub>2</sub>(Ca(HSO<sub>3</sub>)<sub>2</sub>)<sub>3</sub> 3aq.—SrA'Sr(HSO<sub>3</sub>)<sub>2</sub> 5aq.—BaA'Ba(HSO<sub>3</sub>)<sub>2</sub>

VOL. IV.

*Methyl ether* MeA'. (c. 136°). S.G. 9 1.154. Got from AgA' and MeI.

*Ethyl ether* EtA'. Oil. Converted by aniline into two crystalline bodies [144°] and [c. 250°]. The compound O(CMe(OH).CO<sub>2</sub>Et)<sub>2</sub>, formed by the action of nitrous acid on amido-propionic ether, is an oil (80°–86° at 120 mm.) (Curtius, *J. pr.* [2] 38, 472).

*Isoamyl ether* C<sub>4</sub>H<sub>9</sub>A'. Got by distilling the acid with isoamyl alcohol (Simon, *Bl.* [3] 9, 136).

*Amide* CH<sub>3</sub>·CO·CO·NH<sub>2</sub>. [125°]. Got from acetyl cyanide and HCl (Claisen a. Shadwell, *B.* 11, 1566). Prisms or tables (from alcohol).

*Nitrile* v. ACETYL CYANIDE.

*Phenyl hydrazide* CH<sub>3</sub>·C(N·HPh)·CO<sub>2</sub>H. [192°] (F.); [185°] (Japp a. Klingemann, *B.* 20, 3234; *A.* 247, 208; *C. J.* 53, 519). Ppd. when a solution of phenyl-hydrazine hydrochloride is added to a dilute (even 1 in 1000) solution of pyruvic acid (Fischer, *B.* 16, 2241; 17, 578). Prisms, sol. hot water and hot alcohol. Reduced by sodium-amalgam to phenyl-hydrazido-propionic acid [172°]. At 190° it gives off CO<sub>2</sub> and H<sub>2</sub>, and forms the phenyl-hydrazide of di-methyl diketone [242°] and the oily phenyl-hydrazide of aldehyde. The ether CH<sub>3</sub>·C(N·HPh)·CO<sub>2</sub>Et [117°], crystallises in yellow needles (from ligroin).

*o-Chloro-phenyl-hydrazide*

C<sub>6</sub>H<sub>4</sub>Cl.NH.N:CMe·CO<sub>2</sub>H. [178°]. Lemon-yellow needles, forming a crystalline ethyl ether [168°] (Hewett, *C. J.* 53, 211).

*p-Nitro-phenyl-hydrazide*

C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>).NH.N:CMe·CO<sub>2</sub>H. Yellow plates (Fischer a. Ach, *A.* 253, 64). V. sol. hot alcohol.

*p-Sulpho-phenyl-hydrazide*

SO<sub>3</sub>H.C<sub>6</sub>H<sub>4</sub>.NH.N:CMe·CO<sub>2</sub>H. Solid, insol. ether, v. sol. water and alcohol (Pfülf, *A.* 239, 217).—NaA' aq. nodules.

*Phenyl-methyl-hydrazide* C<sub>6</sub>H<sub>5</sub>·N<sub>2</sub>·CMe·CO<sub>2</sub>H. [78°]. Yellowish

needles (Fischer, *B.* 16, 2245; 17, 559). Converted by heating with HClAq into methyl-indole carboxylic acid and NH<sub>3</sub>. The phenyl-ethyl-hydrazide is converted in like manner into ethyl-indole carboxylic acid.

*Di-phenyl-hydrazide*

NPh<sub>2</sub>·N:CMe·CO<sub>2</sub>H. [145°]. White needles (Fischer a. Hess, *B.* 17, 567). Sol. hot benzene and CHCl<sub>3</sub>, forming deep-yellow solutions. Converted into phenyl-indole carboxylic acid by heating with HClAq.

*o-Tolyl-hydrazide*

C<sub>6</sub>H<sub>4</sub>Me.N<sub>2</sub>·H:CMe·CO<sub>2</sub>H. [156°] (J.); [159°] (B.). Formed by saponifying the product of the action of o-diazotoluene chloride on sodium methyl-acetoacetic ether (Japp, *A.* 247, 213), and from o-tolyl-hydrazine hydrochloride and pyruvic acid (Raschen, *A.* 239, 228). Small yellow plates (from benzene). Yields o-tolyl-hydrazido-propionic acid [143°] on reduction. At about 160° it forms the di-o-tolyl-di-hydrazine of di-methyl-di-ketone, a yellow crystalline powder [198°].

*p-Tolyl-hydrazide* C<sub>6</sub>H<sub>4</sub>·N<sub>2</sub>·H:CMe·CO<sub>2</sub>H. [162°]. Formed in the same way as the o-isomeride. Yellow plates (from benzene). At 185° it is converted into the di-p-tolyl-hydrazide of di-methyl-di-ketone [230°]. Gives an ethyl ether C<sub>6</sub>H<sub>4</sub>·N<sub>2</sub>·O<sub>2</sub>·Et [106°], crystallising from ligroin in yellowish plates,

**Methyl-p-tolyl-hydrazide**  $C_9H_{11}N_2O_2$  [83°]. Yellow prisms (Hegel, A. 232, 215).

**Ethyl-p-tolyl-hydrazide**  $C_{12}H_{15}N_2O_2$ . Needles, v. sol. alcohol and ether (H.).

**ψ-Cumyl-hydrazide**

$C_9H_9Me.NH.N:CMc.CO_2H$ . [148°]. Yellow needles (Ruhemann, C. J. 57, 55).

**p-Benzoylphenyl-hydrazide**

$C_9H_7Bz.NH.H:CMc.CO_2H$ . [200°]. Lemon-coloured crystals (Ruhemann a. Blackman, C. J. 55, 616).

(a) **Naphthyl-hydrazide**

$C_{10}H_7.NH.H:CMc.CO_2H$ . [159°] (Fischer, A. 232, 236). Yields  $EtA'$  [100°] (Schlieper, A. 239, 229).

(β) **Naphthyl-hydrazide** [166°]. Yields  $EtA'$  [131°] (Schlieper, A. 236, 176).

(B. 4) **Quinoli-hydrazide**

$C_9H_7.NH.N:CMc.CO_2H$ . [174°]. Formed from pyruvic acid and (B. 4)-hydrazido-quinoline acetate (Dufton, C. J. 59, 758). Light-yellow pp., insol. water, sol. acids and alkalis.

**Oxim**  $CH_3.C(NOH).CO_2H$ . **α-Nitroso-propionic acid**. Formed by the action of cold KOHAq on its ether, which is got by adding a dilute solution of  $KNO_3$  (10 pts.) to methyl-acetoacetic ether dissolved in water (3 pts.), KOH (2 pts.), and some alcohol, the yield being 16 p.c. of the methyl-acetoacetic ether used (V. Meyer a. Züblin, B. 11, 692; Gutknecht, B. 13, 1116). Got also from pyruvic acid and hydroxylamine (V. Meyer a. Janny, B. 15, 1527; Schäfer, A. 264, 153; Hantzsch, B. 24, 50). Crystalline powder, sl. sol. ether, v. sol. water and alcohol. Decomposes suddenly at about 177°. Oxidised by potassium permanganate to ethyl-nitrolic acid  $CH_3.CH(NO)(NO_2)$ . Yields acetonitrile on heating with hydroxylamine hydrochloride. Reduced by tin and HClAq to alanine. Salts.— $KA'$  aq: pearly plates, sol. water.— $BaA'_2$ : soluble prisms.— $Cu_2OA'_2$  aq.— $AgA'$ : white insoluble powder. **Ethyl ether**  $EtA'$ . [94°]. (233° cor.). Formed as above, and also by the action of  $HNO_2$  on methyl-malonie ether and on propionyl-propionic ether (Bergreen, B. 20, 533). Needles or prisms, with weak acid properties.

**References**.—BROMO-, CHLORO-, and OXY-PYRUVIC ACID.

**PYRUVIC ALDEHYDE**  $CH_3.CO.CHO$ . **Methyl-glyoxal**. Got by the action of dilute acids upon  $CH_3.C(OH)(SO_3Na).CH(SO_3Na).NH_2SO_3Na$ , which is got from nitroso-acetone and  $NaHSO_3$  (Pechmann, B. 20, 2543).

**Mono-oxim** v. NITROSO-ACETONE.

**Di-oxim**  $CH_3.C(NOH).CH.NOH$ . **Methyl-glyoxim**. [158°]. Formed by the action of hydroxylamine on  $CH_3.CO.CH.NOH$  or upon  $CH_3.CO.CHCl$  (V. Meyer a. Janny, B. 15, 1165; Treadwell, B. 15, 2787). Small prisms (from alcohol) or needles (by sublimation). Salt.— $AgC_2H_3N_2O_2$  pp.—Diacyetyl derivative

$C_4H_7(NOAc)_2$ . [51°]. Prisms (from ligroin) (Schrömm, B. 16, 2187).

**Phenyl-hydrazide of the oxim**

$CH_3.C(N_2HPh).CH:N.OH$ . [184°]. Formed from nitroso-acetone and phenyl-hydrazine (Pechmann a. Wehsarg, B. 21, 2994; A. 262, 278). Prisms or needles (from alcohol).  $H_2SO_4$  forms a reddish-yellow solution, coloured deep blue by  $FeCl_3$ .  $Ac_2O$  yields  $CH_3.C(N_2HPh).CH:NOAc$  [163°], crystallising in colourless needles.

**Phenyl-methyl-hydrazide of the oxim**  $CH_3.C(N_2PhMe).CH:N.OH$ . [118°]. Orange yellow prisms (from alcohol).

**Phenyl-hydrazide**  $CH_3.CO.CH:N.NHPh$ . [150°]. Formed from sodium acetoacetic ether and diazobenzene chloride (Japp, A. 247, 193, 218; C. J. 53, 519). Plates (from benzene or MeOH). Yields  $CH_3.CO.CH:N.NAcPh$  [93°], crystallising from ligroin in needles.  $NaOEt$  and chloro-acetic ether yield, on saponification of the product,  $CH_3.CO.CH:N.NPh.CO_2H$  [162°], which crystallises from hot water in needles, and is reduced by tin and HClAq to phenyl-amido-acetic acid [127°].

**Di-phenyl-di-hydrazide**

$CH_3.C(N_2HPh).CH:N_2HPh$ . [145°]. Formed by heating the phenyl-hydrazide of acetyl-carbinol with phenyl-hydrazine hydrochloride and  $NaOAc$  in alcohol at 100° (Laubmann, A. 243, 248). Formed also by warming pyruvic aldehyde or its mono-oxim, phenyl-hydrazide, or phenyl-hydrazide of the oxim with phenyl-hydrazine acetate (Pechmann, B. 20, 2543; 21, 2755; Japp, A. 247, 207). Yellow plates or needles (from dilute alcohol), sl. sol. alcohol. Conc.  $H_2SO_4$  forms an olive-green solution, changing through slaty-blue to violet. Yields a crystalline hydrochloride [197°]. Oxidised by  $K_2Cr_2O_7$  and HOAc to  $CH:N.NPh$  crystallising in needles [107°],  $CMc:N.NPh$

whence boiling HClAq produces  $CH:N.NPh$  a colourless oil (150° at 60 mm.), oxidised by alkaline  $KMnO_4$  to the acid  $C_2H_3N_2O_4$  [192°].

**Acetyl derivative of the di-phenyl-di-hydrazide**  $CH_3.C(N_2HPh).CH:N.NPhAc$ . [229°]. Formed from the acetyl derivative of the phenyl-hydrazide and phenyl-hydrazine (Japp, C. J. 53, 519). Yellowish needles.

**Phenyl-methyl-hydrazide**

$CH_3.CO.CH:N.NPhMe$ . [64°]. Formed from the phenyl-hydrazide,  $NaOMe$ ,  $MeOH$ , and  $MeI$  (Japp). Flat needles (from  $MeOH$ ), v. e. sol. alcohol. Converted by phenyl-hydrazine into  $CH_3.C(N_2HPh).CH:N.NPhMe$  [152°], crystallising in pale-yellow needles.

**Phenyl-ethyl-hydrazide**

$CH_3.CO.CH:N.NPhEt$ . [55°]. Prepared in like manner. Prisms (from ligroin).

**PYRUVYL ALCOHOL** v. ACETYL CARBINOL.

## Q

**QUARTENYLIC ACID** v. ISOCROTONIC ACID.

**QUASSIN**  $C_{22}H_{34}O_{10}$  or  $C_{22}H_{36}O_{10}$  or  $C_{22}H_{38}O_{10}$  (Oliveri) or  $C_{22}H_{38}O_{10}$  (Christensen). **Quassin**. [211°]. S. 253 at 22° (O. A. D.); 07 at 15° (C.). S. (chloroform) 48 at 15° (C.).  $[α]_D^{25} = 37.5$  in

$CHCl_3$ . Occurs in quassia-wood (Winckler, *Rep. Pharm.* 54, 85; Wiggers, A. 21, 40; Christensen, *Ar. Ph.* [3] 20, 481; Goldschmidt a. Weidel, *Sitz. W.* 74, 889; Adrian a. Moreaux, *Ph.* [3] 14, 507). Prepared by extracting quassia wood

(10 pts.) with boiling water (45 pts.), evaporating (to 10 pts.) at a gentle heat, ppg. by tannin, mixing the pp. with lead carbonate, and extracting with boiling alcohol. The product is recrystallised from water and alcohol (yield .01 pt.) (Oliveri a. Denaro, *G.* 15, 6).

**Properties.**—Slender monoclinic needles, v. sol. alcohol and chloroform, sl. sol. ether. Sol. conc. HClAq and KOHAq, insol. Na<sub>2</sub>CO<sub>3</sub>Aq. Reduces Fehling's solution (Oliveri), or, according to Allen (*An.* 12, 107), has no reducing power. Not coloured by FeCl<sub>3</sub>. Ppd. by tannin. Quassin appears to be the dimethyl ether of quassic acid, and probably contains two hydroxyls, two CO<sub>2</sub>Me, and two CO groups, and is perhaps a derivative of anthraquinone (Oliveri). Phenyl-hydrazine forms C<sub>27</sub>H<sub>16</sub>O<sub>6</sub>(N<sub>2</sub>HPh), (?), a yellow amorphous powder, decomposing at about 230° without fusion (Oliveri, *G.* 18, 169).

**Reactions.**—1. Boiling dilute (4 p.c.) H<sub>2</sub>SO<sub>4</sub> forms 'quasside' C<sub>27</sub>H<sub>22</sub>O<sub>6</sub>, a white amorphous very bitter substance [194], which reduces Fehling's solution, and is reconverted by boiling dilute alcohol into quassin. —2. Ac<sub>2</sub>O and NaOAc form, on boiling, the amorphous anhydride C<sub>27</sub>H<sub>16</sub>O<sub>6</sub> [150°–158°], sol. alcohol and ether. —3. Bromine forms C<sub>27</sub>H<sub>11</sub>Br<sub>2</sub>O<sub>6</sub>, a very bitter yellow powder [155°]. —4. Fuming HClAq in a sealed tube at 100° forms MeCl and quassic acid. —5. PCl<sub>5</sub> gives C<sub>27</sub>H<sub>10</sub>Cl<sub>2</sub>O<sub>6</sub>, a yellow powder [120°] decomposed on fusion. —6. HIAq and P at 150°–280° form durenene (188°–195°) C<sub>14</sub>H<sub>14</sub> (220°–240°) and anthracene (Oliveri, *G.* 17, 575).

**Quassic acid** C<sub>27</sub>H<sub>22</sub>O<sub>6</sub> or C<sub>26</sub>H<sub>20</sub>O<sub>6</sub>. [245°]. S. 0.043 at 23°. Formed, together with MeCl (2 mols.), by heating quassin with HClAq. Monoclinic prisms (containing aq), sol. hot alcohol, sl. sol. ether. Alkalis give a reddish-yellow colour. FeCl<sub>3</sub> gives a greenish-yellow colour. Reduces Fehling's solution and ammoniacal AgNO<sub>3</sub>. Hydroxylamine forms C<sub>27</sub>H<sub>26</sub>(NOH)<sub>2</sub>O<sub>6</sub> (?), crystallising in rectangular prisms [230°]. —BaA'' 7aq: reddish-yellow crystals. —PbA'' 6aq: white amorphous pp. —FeA''<sub>3</sub>: brownish-green pp.

**QUEBRACHAMINE.** [142°]. Occurs in white quebracho bark (Hesse, *A.* 211, 269). Plates, v. sol. alcohol, benzene, CHCl<sub>3</sub>, and ether. Its alcoholic solution is alkaline and tastes bitter. H<sub>2</sub>SO<sub>4</sub> and K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> give a dark-violet colour.

**QUEBRACHINE** C<sub>27</sub>H<sub>22</sub>N<sub>2</sub>O<sub>6</sub>. [216°]. [α]<sub>D</sub><sup>20</sup> = 62.5 in a 2 p.c. alcoholic solution at 15°; = 18.6 in chloroform. Occurs in white quebracho bark (Hesse, *B.* 18, 2308; *A.* 211, 254). Colourless needles, sol. alcohol, ether, benzene, and CHCl<sub>3</sub>, v. sl. cold water, NaOHAq, and NH<sub>4</sub>Aq. Dextrorotatory. Its solutions are alkaline, bitter, and poisonous. Its solution in H<sub>2</sub>SO<sub>4</sub> is turned blue by PbO<sub>2</sub> or K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, and finally brown. FeCl<sub>3</sub> gives no colour.

**Salts.**—B'HCl.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub> 5aq: crystals.—B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub> 8aq: cubes or short prisms, v. sol. hot water.—B'<sub>2</sub>H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.—Tartrate B'<sub>2</sub>H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> 6aq.—Citrate B'<sub>2</sub>C<sub>2</sub>H<sub>2</sub>O<sub>7</sub>: nodular groups of needles.

**Hypoquembrachine** C<sub>12</sub>H<sub>12</sub>N<sub>2</sub>O<sub>2</sub>. [80°]. Strong base with bitter taste, v. sol. alcohol and ether, forming yellow amorphous salts. Platinochloride.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub> 4aq (Hesse, *A.* 211, 264).

**QUEBRACHITE** C<sub>27</sub>H<sub>16</sub>MeO<sub>6</sub>. [187°]. S.G. 1.54. (c. 210° in vacuo). [α]<sub>D</sub><sup>20</sup> = -80°. Occurs in the seeds of *Aspidosperma quebracho*, from which it can be extracted with alcohol (Tanret,

*C. R.* 109, 908). Trimetric prisms with sweet taste, v. sol. water and alcohol, insol. ether. Does not ferment with yeast or reduce Fehling's solution. Reduces ammoniacal AgNO<sub>3</sub>. Not affected by dilute acids or alkalis at 100°. Ppd. by ammoniacal lead acetate, but not by lead subacetate. Heated with HI it gives off MeI and a little benzene. Ac<sub>2</sub>O and ZnCl<sub>2</sub> form an acetyl derivative [89°]. Gives on heating with HNO<sub>3</sub> the same reactions as inositol.

**QUEBRACHO BARK.** Quebracho blanco, or white quebracho bark, used as a febrifuge, contains about .8 p.c. of alkaloids, consisting of ASPIDOSPERMINE, ASPIDOSPERMATINE, ASPIDOSAMINE, QUEBRACHINE, HYPOQUEBRACHINE, QUEBRACHAMINE, and QUEBRACHOL (Hesse, *A.* 211, 251).

**QUEBRACHO GUM.** Occurs in quebracho Colorado, the bark of *Loxopterygium Lorentii* (Jean, *Bl.* 28, 6; Arata, *Anales de la Sociedad Científica Argentina*, July 1878; Feb. 1879; *C. J.* 34, 986). Brittle concretions, with astringent taste, sol. boiling water and alcohol, insol. ether. Quebracho gum contains quebrachitanic acid, a pale-red amorphous mass, m. sol. hot water, giving a green colour with FeCl<sub>3</sub>, turned dark red by NaOAc. Quebrachitanic acid ppts. Pb(OAc)<sub>2</sub>, gelatin, albumen, and alkaloids. It yields pyrocatechin and a liquid (100°–120°) on distillation. Potash-fusion gives pyrocatechuic acid and phloroglucin; nitric acid yields oxalic and picric acids.

**QUEBRACHOL** C<sub>26</sub>H<sub>20</sub>O. [125°]. [α]<sub>D</sub><sup>20</sup> = -29.3°. Occurs in white quebracho bark (Hesse, *A.* 211, 272; 228, 289). Plates, v. e. sol. alcohol and ether, insol. water and alkalis. When the solution in chloroform is shaken with H<sub>2</sub>SO<sub>4</sub>, the chloroform is coloured red (cf. CHOLESTERYN).

*Acetyl derivative* C<sub>26</sub>H<sub>20</sub>OAc. [115°].

**QUERCETAGETIN** C<sub>27</sub>H<sub>22</sub>O<sub>11</sub> 4aq. Yellow crystals, extracted by alcohol from the blossoms of the common marigold, *Tagetes patula* (Latour a. Magnier, *Bl.* [2] 28, 337).

**QUERCETIN** C<sub>15</sub>H<sub>10</sub>O<sub>11</sub> 8aq (Liebermann a. Hamburger, *B.* 12, 1178) or C<sub>15</sub>H<sub>10</sub>O<sub>10</sub> (Herzig, *M.* 12, 172). (β)-Rhamnetin (Herzig, *M.* 10, 561). [above 250°]. S. (alcohol) 5.5 at 78°; 4 in the cold (Stein, *J.* 1862, 499). Mol. w. (by Raoult's method) 258 (calc. 302). Formed, together with isodulcitol, by the action of dilute H<sub>2</sub>SO<sub>4</sub> on quercitron, a yellow dye-stuff consisting of the shavings of the bark of *Quercus tinctoria*, growing in the United States (Rigaud, *A.* 90, 289). Rutin and robinin also yield quercetin when treated with dilute H<sub>2</sub>SO<sub>4</sub> (Zwenger a. Dronke, *A.* 123, 153; *Suppl.* 1, 261; Sehunck, *C. J.* 53, 262; Hlasiwetz, *A.* 112, 96; *J. pr.* 94, 65). Occurs in Persian berries (Kane, *A. Ch.* [3] 8, 380; Bolley, *C. J.* 13, 327), in the ripe fruit, flowers, and leaves of the horse-chestnut (Rochleder, *A.* 112, 112), in the berries of the seabuckthorn (*Ehipphobos rhamnoides*), in apple-tree bark, in tea-leaves, and in catechu (Loewy, *Fr.* 12, 127).

**Properties.**—Lemon-yellow crystalline powder, sl. sol. water, v. sl. sol. ether. Gives off water of crystallisation at 130°. May be sublimed as yellow needles. Dissolves in alkalis, forming yellow solutions. Dyes fabrics mordanted with alumina yellow; with iron, grey or black. Its alcoholic solution is coloured dark green by FeCl<sub>3</sub>, the colour becoming dark red on warming.

$\text{Pb}(\text{OAc})_2$  gives a brick-red pp. Reduces  $\text{AgNO}_3$  in the cold, and Fehling's solution on heating.

**Reactions.**—1. On fusion with potash it yields phloroglucin and quercetic acid, and by prolonged fusion, paradatiscetin  $\text{C}_{15}\text{H}_{10}\text{O}_8$ , quercimeric and protocathechuic acid.—2. Boiling dilute alcoholic potash gives phloroglucin and protocathechuic acid (Herzig, *M.* 6, 863).—3.  $\text{KClO}_3$  and  $\text{HCl}$  yield protocathechuic acid.—4. Sodium-amalgam forms phloroglucin, a compound  $\text{C}_{15}\text{H}_{12}\text{O}_8$ , crystallising in needles, sl. sol. water, and a compound  $\text{C}_8\text{H}_6\text{O}_8$ , which forms granular crystals [130°], v. sol. water.—5. Bromine in  $\text{HOAc}$  forms  $\text{C}_{21}\text{H}_{14}\text{Br}_2\text{O}_{11}$ , crystallising in lemon-yellow needles [237°] and yielding  $\text{C}_{21}\text{H}_{14}\text{Ac}_2\text{Br}_2\text{O}_{11}$ . Excess of Br in  $\text{HOAc}$  forms  $\text{C}_{21}\text{H}_{14}\text{Br}_3\text{O}_{11}$ , whence  $\text{C}_{21}\text{H}_{14}\text{Ac}_3\text{Br}_3\text{O}_{11}$  may be got, crystallising from  $\text{HOAc}$  in needles [253°]. Liebermann obtained the compounds  $\text{C}_{21}\text{H}_{14}\text{Br}_2\text{O}_{11}$ ,  $\text{C}_{21}\text{H}_{14}\text{Ac}_2\text{Br}_2\text{O}_{11}$  [218°],  $\text{C}_{21}\text{H}_{14}\text{Br}_3\text{O}_{11}$ , and  $\text{C}_{21}\text{H}_{14}\text{Ac}_3\text{Br}_3\text{O}_{11}$  [228°], all crystallising in needles.—6. *Phenyl cyanate* at 160° forms  $\text{C}_{21}\text{H}_{14}\text{O}_8(\text{O.CO.NHPh})_3$ , a white amorphous powder [200°–205°] (Tesner, *B.* 18, 2609).—7. Ammonia at 150° forms amorphous 'quercetamide' (Schützenberger a. Paraf, *Z.* 1862, 41).

**Salts.**— $\text{C}_{15}\text{H}_{10}\text{K}_2\text{O}_{13}$  (?).— $\text{C}_{15}\text{H}_{10}\text{Na}_2\text{O}_{13}$  (?).— $\text{C}_{15}\text{H}_{10}\text{ZnO}_{13}$  (H. a. F.).

**Acetyl derivative**  $\text{C}_{21}\text{H}_{14}\text{Ac}_2\text{O}_{11}$  or  $\text{C}_{15}\text{H}_8\text{Ac}_2\text{O}_8$  (Herzig, *M.* 5, 72; 6, 890; 9, 537; 10, 561; 12, 174; cf. Liebermann, *B.* 12, 1178; *A.* 196, 319). [191°]. Formed by boiling quercetin or rhamnetin with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$ . Needles (from alcohol). Liebermann obtained  $\text{C}_{21}\text{H}_{14}\text{Ac}_2\text{O}_{11}$  [198°], crystallising in needles.

**Methyl ether**  $\text{C}_{15}\text{H}_{10}(\text{OMe})$ . *Rhamnetin*. Formed, together with isodulcite, by heating xanthorhamnin with dilute  $\text{H}_2\text{SO}_4$  (Gellatly, *N. E. P. J.* 7, 256; Liebermann a. Hörmann, *B.* 11, 1618; Herzig, *M.* 6, 889; 9, 560; 12, 175). Lemon-yellow powder, nearly insol. water, alcohol, and ether, v. sol. hot phenol. Forms a yellow solution in  $\text{KOH}$  aq. Reduces ammoniacal  $\text{AgNO}_3$  and hot Fehling's solution. Yields protocathechuic acid and phloroglucin on fusion with potash or on treatment with sodium-amalgam (Smorawski, *B.* 12, 1595). Converted by  $\text{HI}$  into quercetin and  $\text{MeI}$ . Dyes iron mordants black and alumina yellow. Yields  $\text{C}_{15}\text{H}_8\text{Ac}_2\text{O}_8(\text{OMe})$  [185°].  $\text{KOH}$  and  $\text{EtI}$  give ethyl-rhamnetin [108°], whence  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  form an acetyl-ethyl-rhamnetin [157°]. Rhamnetin yields also (tetra-?) propionyl [158°–162°] and (tetra-?) benzoyl [212°] derivatives, and an acetyl-dibromo-derivative [212°].

**Methyl derivative**  $\text{C}_{21}\text{H}_{14}\text{Me}_2\text{O}_{11}$  or  $\text{C}_{15}\text{H}_8\text{Me}_2\text{O}_8$ . [167°]. Formed from quercetin,  $\text{KOAc}$ , and  $\text{MeI}$  (Herzig, *M.* 5, 83) and got also by heating xanthorhamnin with  $\text{KMeSO}_4$  and  $\text{MeOH}$  at 120°, and from rhamnetin,  $\text{KOH}$ , and  $\text{MeI}$  (Liebermann a. Hörmann, *A.* 196, 317; Herzig, *M.* 6, 889; 9, 552). Golden needles, sl. sol. alcohol, converted by alcoholic potash at 140° into the di-methyl derivative of protocathechuic acid. Boiling  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  give  $\text{C}_{21}\text{H}_{14}\text{Ac}_2\text{Me}_2\text{O}_{11}$  or  $\text{C}_{15}\text{H}_8\text{Ac}_2\text{Me}_2\text{O}_8$ , crystallising in needles [167°].

**Ethyl derivative**  $\text{C}_{21}\text{H}_{14}\text{Et}_2\text{O}_{11}$  or  $\text{C}_{15}\text{H}_8\text{Et}_2\text{O}_8$ . [122°]. Got by boiling quercetin with alcoholic potash and  $\text{EtI}$  (Herzig, *M.* 9, 687). Yellow needles, m. sol. alcohol. Yields

$\text{C}_8\text{H}_8(\text{OEt})_2\text{CO}_2\text{H}$  when heated with potash at 140°.  $\text{Ac}_2\text{O}$  and sodium acetate give the colourless acetyl derivative  $\text{C}_{21}\text{H}_{14}\text{Ac}_2\text{Et}_2\text{O}_{11}$  or  $\text{C}_{15}\text{H}_8\text{Ac}_2\text{Et}_2\text{O}_8$ , crystallising in needles [153°]. Mol. w. (by Raoult's method) c. 426 (Herzig, *M.* 12, 172).

**A compound of quercetin and rhamnetin** which sometimes occurs in Persian berries (Herzig, *M.* 10, 561) yields an acetyl derivative [171°], an acetyl-ethyl derivative [142°], and an ethyl derivative [102°].

**Paradatiscetin**  $\text{C}_{15}\text{H}_{10}\text{O}_8$ . Formed from quercetin by potash-fusion (Hlasiwetz a. Pfaundler, *J. pr.* 94, 65). Yellowish needles (from dilute alcohol), nearly insol. water, m. sol. ether. Acid in reaction.  $\text{FeCl}_3$  colours its alcoholic solution violet. Potash forms a yellow solution, turning green in air. Reduces  $\text{AgNO}_3$  and Fehling's solution on heating. Potash-fusion yields phloroglucin but not protocathechuic acid. Boiled with water and  $\text{BaCO}_3$  it yields  $\text{BaA}'_2\cdot 2\text{aq.}$ — $\text{SrA}'_2\cdot 2\text{aq.}$

**Quercetic acid**  $\text{C}_{15}\text{H}_{10}\text{O}_8\cdot 3\text{aq}$  (?). Formed, together with phloroglucin, by heating quercetin (1 pt.) with moist  $\text{KOH}$  (3 pts.) till a sample no longer gives a flocculent pp. with  $\text{HCl}$  and the residue quickly turns dark red at the edges (Hlasiwetz, *A.* 112, 96; 119, 213; *J. pr.* 94, 65). Slender silky efflorescent needles, sl. sol. cold water, v. sol. alcohol and ether. Its aqueous solution turns yellow, and finally crimson, in air.  $\text{H}_2\text{SO}_4$  forms a brown solution, whence water gives a red pp. forming a purple solution in  $\text{NH}_4\text{Aq}$ .  $\text{FeCl}_3$  gives a blue-black colour. Reduces  $\text{AgNO}_3$ . Potash-fusion gives protocathechuic acid.  $\text{AcCl}$  forms  $\text{C}_{15}\text{H}_8\text{Ac}_2\text{O}_8$ , crystallising from alcohol in prismatic needles.

**Quercimeric acid**  $\text{C}_{15}\text{H}_{10}\text{O}_8\cdot \text{aq}$  (?). Formed from quercetin by potash-fusion. Colourless prisms, v. sol. water, alcohol, and ether. Tastes bitter. Alkalis colour its solutions purple-red.  $\text{FeCl}_3$  gives a dark-blue colour. Reduces  $\text{AgNO}_3$  and Fehling's solution. Potash-fusion gives protocathechuic acid.

**QUERCIN**  $\text{C}_{15}\text{H}_8(\text{OH})_8$ . [340°]. Occurs in oak bark, being obtained from the mother-liquors in the preparation of quercite (Gerber, *A.* 48, 348; Vincent a. Delachanal, *C. R.* 104, 1855; Friedel, 105, 95; *Bl.* [2] 48, 113). Efflorescent monoclinic prisms (containing 2 aq.), sl. sol. water, insol. boiling alcohol. Inactive to light. Does not ferment with yeast, nor reduce Fehling's solution. Does not react with phenyl-hydrazine. Reduces ammoniacal  $\text{AgNO}_3$  after addition of  $\text{NaOH}$ . Gives a gelatinous pp. with lead sub-acetate. After evaporation with  $\text{HNO}_3$  it gives a rose-red colour with  $\text{NH}_4\text{Aq}$  and  $\text{CaCl}_2$ . Not coloured by boiling  $\text{NaOH}$  aq.

**Acetyl derivative.**— $\text{C}_{15}\text{H}_8(\text{OAc})_8$ . [301°].

**QUERCITANNIC ACID**  $\text{C}_{17}\text{H}_{10}\text{O}_9$  or  $\text{C}_{15}\text{H}_8\text{O}_{10}$ . S. 6. S. (ether) 035. Occurs in oak bark, from which it is got by powdering, sifting from bast fibres, extracting with dilute alcohol, and shaking the filtrate with ether and  $\text{EtOAc}$ . The acetic ether when evaporated deposits ellagic acid. The filtrate is evaporated to dryness, and the residue washed with ether and then extracted with  $\text{Et}_2\text{O}$  and  $\text{EtOAc}$  (Etti, *Sitz. W.* [2] 81, 495; *M.* 1, 264; 4, 514; cf. Stenhouse, *A.* 45, 16; Böttinger, *A.* 202, 270; 240, 331; 263, 112; Löwe, *Fr.* 20, 210). Occurs

also in ten (Rochleder, *A.* 63, 205). Reddish-white powder.  $\text{FeCl}_3$  colours the alcoholic solution dark blue.  $\text{Pb}(\text{OAc})_2$  ppts. the alcoholic solution. Quercitannic acid is not a glucoside (Etti). At  $130^\circ$  to  $140^\circ$  it forms an anhydride which gives  $\text{C}_{19}\text{H}_{10}\text{BaO}_{17}$  (Etti). On evaporating with  $\text{NaCl}$  it is converted into a mixture of anhydrides which give with bromine-water an amorphous pp.  $\text{C}_{19}\text{H}_8\text{Br}_2\text{O}_{16}$ , m. sol. alcohol and  $\text{EtOAc}$ , v. e. sol. a mixture of these solvents, reacts with hydroxylamine, and is converted by  $\text{Br}$  into  $\text{C}_{19}\text{H}_{10}\text{Br}_2\text{O}_{16}$ , whence  $\text{Ac}_2\text{O}$  forms  $\text{C}_{19}\text{H}_8\text{Ac}_2\text{Br}_2\text{O}_{16}$ .

**QUERCITE**  $\text{C}_{19}\text{H}_{10}\text{O}_8$ . *Penta-oxy-benzene hexahydrate?* Mol w. 164. [ $234^\circ$ ] Böttlinger, *B.* 14, 1598. S.G. 1.51-585. S. 9 at  $12^\circ$ ; 11 at  $20^\circ$ .  $[\alpha]_D = 24.17$ . H.C. v. 710, 100 (Berthelot a. Recoura, *A. Ch.* [6] 13, 341). H.F. 263, 200. R. 58-95 in a 7-7 p.c. aqueous solution (Kunonnikoff). Occurs in acorns (Braconnot, *A. Ch.* [3] 27, 392; Dessaignes, *A.* 81, 103, 251; Prunier, *A. Ch.* [5] 15, 5; *C. R.* 84, 1318; 85, 808; 86, 338, 1460; Hofmann, *A.* 190, 282).

**Preparation.**—Acorns are extracted with cold water, the extract concentrated at  $40^\circ$ , ppd. by lead subacetate, filtered, mixed with yeast to remove sugar, and, after fermentation, freed from lead by  $\text{H}_2\text{S}$ , and evaporated to crystallisation.

**Properties.**—Monoclinic prisms,  $a:b:c = 800:1:766$ ,  $\beta = 68^\circ 57'$ , insol. ether, benzene, and chloroform, v. sl. sol. hot alcohol. Does not undergo alcoholic fermentation. Dextrorotatory. Does not render borax solution acid.

**Reactions.**—1. At  $100^\circ$  it slowly loses water, forming  $\text{C}_{19}\text{H}_{10}\text{O}_{10}$  (?). At  $240^\circ$  in *vacuo* it gives  $\text{C}_{12}\text{H}_2\text{O}_6$  [ $230^\circ$ ], v. sl. sol. water. Rapidly heated to  $290^\circ$  it swells up and gives off quinhydrone and hydroquinone.—2. *Potash-fusion* gives quinone, hydroquinone,  $\text{CO}_2$ , formic acid, and oxalic acid.—3.  $\text{H}_2\text{SO}_4$  and  $\text{MnO}_2$  give quinone.—4. Conc.  $\text{HClAq}$  forms, at  $100^\circ$ ,  $\text{C}_6\text{H}_5\text{Cl}(\text{OH})$ , [ $200^\circ$ ], sol. ether, and viscous  $\text{C}_6\text{H}_5\text{ClO}_2$ , which is converted by baryta-water into amorphous quercitan  $\text{C}_6\text{H}_{10}\text{O}_4$ , sol. water and alcohol, insol. ether.  $\text{HClAq}$  at  $120^\circ$ – $140^\circ$  gives  $\text{C}_6\text{H}_5\text{Cl}_2(\text{OH})$ , [ $155^\circ$ ], converted by further treatment with  $\text{HCl}$  into  $\text{C}_6\text{H}_5\text{Cl}_3$ , [ $102^\circ$ ].—5. Distillation with  $\text{HIAq}$  forms benzene, phenol, iodo-phenol, quinone, hydroquinone, and hexane.—6. *Nitric acid* forms mucic and tri-oxy-glutaric acids (Kiliani a. Scheibler, *B.* 22, 517).—7. *Phenyl cyanate* at  $165^\circ$  forms  $\text{C}_6\text{H}_5(\text{O.CO.NHPh})_3$ , [ $120^\circ$ – $140^\circ$ ], a white amorphous powder (Tesmer, *B.* 18, 2606). 8. *Benzoic acid* at  $200^\circ$  forms solid 'benzo-quercite'  $\text{C}_{19}\text{H}_{10}\text{Bz}_2\text{O}_3$  (?) insol. water, sol. alcohol and ether. *Stearic acid* forms a similar body, while tartaric acid gives 'quercitartaric acid'  $\text{C}_{22}\text{H}_{12}\text{O}_{27}$  (Berthelot, *C. R.* 44, 452; *A. Ch.* [3] 54, 82).

**Salts.**— $(\text{C}_6\text{H}_5\text{O})_2\text{Ba}3\text{aq}$ : amorphous, sol. water and alcohol.— $(\text{C}_6\text{H}_5\text{O})_2\text{CaSO}_42\text{aq}$ .

**Acetyl derivatives.** The compounds  $\text{C}_6\text{H}_{11}\text{AcO}$ ,  $\text{C}_6\text{H}_{10}\text{Ac}_2\text{O}$ ,  $\text{C}_6\text{H}_8\text{Ac}_3\text{O}$ ,  $\text{C}_6\text{H}_6\text{Ac}_4\text{O}$ , and  $\text{C}_6\text{H}_4\text{Ac}_5\text{O}$  have been prepared.

**Butyryl derivatives.** Heating with butyric acid gives rise to  $\text{C}_6\text{H}_{11}(\text{C}_4\text{H}_7\text{O})\text{O}$ ,  $\text{C}_6\text{H}_9(\text{C}_4\text{H}_7\text{O})_2\text{O}$ , and  $\text{C}_6\text{H}_7(\text{C}_4\text{H}_7\text{O})_3\text{O}$ , all being amorphous with bitter taste.

**Pentanitate**  $\text{C}_6\text{H}_8(\text{NO})_5$ . Formed from quercite (1 pt.),  $\text{H}_2\text{SO}_4$  (10 pts.) and  $\text{HNO}_3$

(4 pts.) (Hofmann, *A.* 190, 288). Resin, insol. water, sol. alcohol and ether. Explodes when heated. Zinc-dust and alcoholic soda give off the  $\text{N}$  as  $\text{NH}_3$ .

**QUERCITRIN**  $\text{C}_{24}\text{H}_{30}\text{O}_{12}$  or, more probably,  $\text{C}_{24}\text{H}_{28}\text{O}_{12}$  (Herzig, *M.* 14, 53). [ $168^\circ$ ]. S. 0.4 in the cold; 7 at  $100^\circ$ . S. (alcohol) 4 in the cold 29 at  $78^\circ$  (Stein). S. (ether) 8 (Schunck, *C. J.* 53, 261). Occurs in quercitron-bark, the bark of *Quercus tinctoria* (Bolley, *A.* 37, 101; 62, 136; Rochleder, *J. pr.* 77, 34; Rigaud, *A.* 90, 283; Zwenger a. Drönke, *A. Suppl.* 1, 266; Stein, *J. pr.* 85, 351; Hlasiwetz, *A.* 112, 109). Occurs also in fully-developed horse-chestnut leaves (Rochleder a. Kawaler, *Sitz. W.* 55 [2] 46), in leaves of the ash (Gintl, *Z.* [2] 4, 732), and in leaves of *Andromeda japonica* (Eykmann, *R. T. C.* 2, 200).

**Preparation.**—Quercitron bark is exhausted with alcohol, and the evaporated extract dissolved in water and shaken with ether. The ethereal solution is evaporated, the residue dissolved in alcohol, and the quercitrin ppd. by water and crystallised from boiling water (Löwe, *Fr.* 14, 233; cf. Herzig, *M.* 6, 877).

**Properties.**—Yellow needles or plates (containing 3aq). Neutral and tasteless. Nearly insol. cold water, sol. alkalis and  $\text{HOAc}$ .  $\text{FeCl}_3$  colours its solution dark green.  $\text{FeSO}_4$  gives no colour. Ppd. by  $\text{Pb}(\text{OAc})_2$ . Reduces aqueous  $\text{AgNO}_3$  in the cold, and Fehling's solution after long boiling. Boiling dilute acids split it up into quercetin (*q. v.*) and isodulcitol (Liebermann a. Hamburger, *B.* 12, 1178). Bromine forms  $\text{C}_{24}\text{H}_{22}\text{Br}_2\text{O}_{12}$ , which is crystalline and is decomposed by acids into isodulcitol and tetra-bromo-quercetin.

**Salt.**— $\text{C}_{24}\text{H}_{26}\text{K}_2\text{O}_{12}$ : yellow pp.

**Violaquercitrin**  $\text{C}_{22}\text{H}_{24}\text{O}_{12}$ . Occurs in *Viola tricolor* (Mandelin, *J.* 1893, 1369). Yellow needles (from water). Split up by dilute acids into glucose and quercetin.

**QUILLAJIC ACID**  $\text{C}_{19}\text{H}_{16}\text{O}_{10}$ . Extracted by water from the bark of *Quillaja Saponaria* (Kobert, *C. C.* 1888, 972). White flakes, sol. water and alcohol, insol. ether. Coloured dark red by  $\text{H}_2\text{SO}_4$ . Boiling dilute acids split it up into sapogenin and an unfermentable glucose. The  $\text{Na}$  salt violently attacks the mucous membrane, and is very poisonous when injected into the blood.

**QUINACETOPHENONE** is DI-OXY-ACETOPHENONE.

**QUINALDINE** v. METHYL-QUINOLINE.

**QUINALDINIC ACID** v. QUINOLINE CARBOXYLIC ACID.

**QUINAMINE** v. vol. ii. p. 179.

**QUINAMICINE** v. vol. ii. p. 180.

**QUINAMIDINE** v. CINCHONA BASES.

**QUINANISOLE** v. Methyl derivative of Oxy-quinoline.

**QUINAZOLE** v. METHYL-INDAZINE.

**QUINAZOLINE**. This name is given to the ring  $\text{C}_8\text{H}_4 \begin{smallmatrix} \text{CH:N} \\ \text{N=CH} \end{smallmatrix}$ ; v. Oxy-quinazoline.

**QUINAZOLINE DIHYDRIDE**  $\text{C}_8\text{H}_6\text{N}_2$ , i.e.  $\text{C}_8\text{H}_4 \begin{smallmatrix} \text{CH}_2\text{NH} \\ \text{N=CH} \end{smallmatrix}$  [ $127^\circ$ ]. Formed by reducing o-nitro-benzyl-formamide by  $\text{Zn}$  and  $\text{HClAq}$  (Gabriel a. Jansen, *B.* 23, 2814; 24, 3097). Yellowish crystals, sol. warm water, forming an

alkaline solution.—B'HCl.—B'C<sub>2</sub>H<sub>4</sub>N<sub>2</sub>O<sub>2</sub>. [215°]. Small crystals, sl. sol. water.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>.

QUININE v. vol. ii. p. 181.

QUINETHONIC ACID C<sub>12</sub>H<sub>10</sub>O<sub>8</sub> i.e.

C<sub>6</sub>H<sub>4</sub>(OEt).C<sub>6</sub>H<sub>4</sub>O<sub>2</sub>. [146°]. Occurs in urine after a dose of C<sub>6</sub>H<sub>5</sub>OEt (Kossel, *H.* 4, 296; 7, 292; Lehmann, *H.* 13, 181). Crystalline. Lævorotatory. Does not reduce Fehling's solution. Converted by dilute H<sub>2</sub>SO<sub>4</sub> into crystalline C<sub>6</sub>H<sub>4</sub>O<sub>2</sub>. HIAq forms hydroquinone. Oxidising agents yield quinone. —KA'Aq: monoclinic crystals.—AgA'aq. Forms with C<sub>2</sub>H<sub>5</sub>O.SO<sub>3</sub>H the double salt PhO.SO<sub>3</sub>BaA'aq (dried at 110°) and with cresol and indoxyl the corresponding C<sub>6</sub>H<sub>4</sub>O.SO<sub>3</sub>BaA'aq and C<sub>6</sub>H<sub>4</sub>NSO<sub>3</sub>BaA', all three being crystalline (Hoppe-Seyler, *H.* 7, 424).

QUINHYDRONE C<sub>12</sub>H<sub>10</sub>O<sub>4</sub>. Formed by mixing aqueous solutions of quinone and hydroquinone; by oxidising hydroquinone; and by reducing quinone (Wöhler, *A.* 51, 153; Liebermann, *B.* 10, 1614, 2000; Hesse, *A.* 200, 248; Nietzki, *A.* 215, 130; Wichelhaus, *B.* 5, 840; 12, 1500; Stenhouse & Groves, *B.* 13, 1305). Brownish-red prisms, with green metallic lustre. May be sublimed. Sl. sol. cold water, v. sol. alcohol and ether, forming yellow solutions. Decomposed by boiling water, giving off quinone and leaving a solution of hydroquinone. Its ammoniacal solution is green. Reduces ammoniacal AgNO<sub>3</sub>.

QUINIC ACID C<sub>7</sub>H<sub>10</sub>O<sub>6</sub> i.e. C<sub>6</sub>H<sub>4</sub>(OH).CO<sub>2</sub>H. Mol. w. 192. [162° cor.]. S.G. 8<sup>3</sup> 1.637 (Henry & Plisson, *B.* J. 10, 186). S. 40 at 9°. [α]<sub>D</sub> = -44° at 20° in a 20 p.c. solution (Thomsen, *J. pr.* [2] 35, 156). H.C. 833,700. H.F. 238,300 (Berthelot & Recoura, *C. R.* 105, 144; *Bl.* [2] 48, 703; *A. Ch.* [6] 13, 342). R<sub>∞</sub> 66.52 in an 18 p.c. aqueous solution (Kanonnikoff, *J. pr.* [2] 31, 348). Occurs as calcium salt in cinchona bark (Hoffmann, *Crell's Ann.* 2, 314; Vauquelin, *A. Ch.* 59, 162; Pelletier & Caventou, *A. Ch.* [2] 15, 840; Liebig, *P.* 21, 1; 29, 70; Baup, *A. Ch.* [2] 61, 5; *A.* 6, 7; Woskresensky, *A.* 27, 260; Hesse, *A.* 110, 194; 112, 52; 114, 292; 176, 124; Clemm & Will, *A.* 110, 845). Occurs also in the bilberry plant (*Vaccinium Myrtillus*) (Zwenger, *A.* 115, 108; 129, 203; *Suppl.* 1, 77), in the leaves and beans of the coffee-plant (*Z.*), and in hay (O. Loew, *J. pr.* [2] 19, 310; 20, 476).

**Preparation.**—Cinchona bark is extracted with dilute H<sub>2</sub>SO<sub>4</sub>, the extract ppd. by milk of lime, filtered, and evaporated. The residue is boiled with alcohol and the calcium quinate left undissolved is crystallised from water and decomposed by oxalic acid.

**Properties.**—Monoclinic prisms. V. e. sol. water, m. sol. alcohol, nearly insol. ether. Lævorotatory.

**Reactions.**—1. Heated to 200°–225° it gives off aq, forming quinide C<sub>6</sub>H<sub>4</sub>O<sub>4</sub>, a crystalline anhydride, v. sol. water, sl. sol. dilute alcohol. Quinide is acid in reaction, and is reconverted by bases into quinic acid. On dry distillation quinic acid gives hydroquinone, phenol, benzoic acid, and pyrocatechin.—2. Ac<sub>2</sub>O at 170° forms tri-acetyl-quinide C<sub>6</sub>H<sub>4</sub>(OAc)<sub>3</sub> <O [182°] and tetra-acetyl-quinic acid (Erwig & Königs, *B.* 22, 1458; cf. Hesse, *A.* 200, 233). By further heating with Ac<sub>2</sub>O at 240°–250° monoclinic crystals of iso-tri-acetyl-quinide [189°] are obtained.—3. Bromine added to an aqueous

solution forms protocatechuic acid (Hesse).—4. Hot H<sub>2</sub>SO<sub>4</sub> forms CO and hydroquinone disulphonic acid.—5. Hydroquinone is formed by boiling the aqueous solution with PhO<sub>2</sub>. Distillation with MnO<sub>2</sub> and dilute H<sub>2</sub>SO<sub>4</sub> yields quinone (detection of quinic acid in bark: Stenhouse, *A.* 59, 100).—6. HNO<sub>3</sub> gives oxalic acid. 7. KClO<sub>4</sub> and HCl give chlorinated quinones and chlorinated acetones (Städeler, *A.* 69, 300; 111, 293).—8. Conc. HIAq at 120° reduces it to benzoic acid (Lautemann, *A.* 125, 9).—9. Conc. HClAq at 150° gives *p*-oxy-benzoic acid and hydroquinone (Hesse, *A.* 200, 232). Dilute (3 p.c.) HClAq at 100°–120° forms phenol, hydroquinone, and *p*-oxy-benzoic acid (Chadounski, *C. C.* 1888, 1029).—10. Fuming HBrAq at 130° gives protocatechuic and benzoic acids (Fittig, *A.* 193, 197).—11. PCl<sub>5</sub> forms *m*-chloro-benzoyl chloride (Graebe, *A.* 138, 197). 12. Gives protocatechuic acid on fusion with KOH or NaOH.—13. Boiling with iodine and KOHAq yields iodoform.—14. Calcium quinate fermented by *schizomycetes* in presence of air yields protocatechuic acid, in absence of air it gives propionic, acetic, and formic acids (Löw, *B.* 14, 450).

**Salts.**—NaA' 2aq.—NaA' 5aq. S. 200.—BaA', 6aq: dodecahedra, very soluble in water.—CaA', 10aq. S. 17 at 16°. Plates, insol. alcohol.—CaA'Ac aq (Gundelach, *B.* 9, 852).—SrA', 10aq.—SrA', 15aq.—MgA', 6aq.—CdA', 5aq. S. 4 in the cold.—ZnA', 5aq.—CoA', 5aq.—NiA', 5aq: crystals. CuA', 5aq: blue needles.—CuC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> 2aq. S. 0.9 at 18°.—PbA', 2aq: needles, sol. alcohol, v. e. sol. water.—PbC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>. Amorphous, insol. water.—MnA', S. 5 in the cold.—FeC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>.—AgA': mammellated groups of crystals.

**Ethyl ether EtA'.** Viscid mass, with bitter taste, v. sol. water and alcohol. Converted by boiling Ac<sub>2</sub>O into C<sub>6</sub>H<sub>4</sub>(OAc).CO<sub>2</sub>Et crystallising from water in plates [135°], sl. sol. boiling water.

#### Tetra-acetyl derivative

C<sub>6</sub>H<sub>4</sub>(OAc)<sub>4</sub>.CO<sub>2</sub>H. [130°–136°]. Formed by heating quinic acid with Ac<sub>2</sub>O and ZnCl<sub>2</sub> (Erwig & Koenigs, *B.* 22, 1461). Crystalline crusts, sl. sol. cold water, insol. ligroin.—AgA': needles.

**Anilide** C<sub>13</sub>H<sub>11</sub>NO<sub>4</sub>. [174°]. Formed by heating quinic acid with aniline at 180°. Small silky needles (containing aq), v. sol. water and alcohol, sl. sol. ether.

QUINICINE v. CINCHONA BASES.

QUINIDE v. QUINIC ACID.

QUINIDINE v. vol. ii. p. 180.

QUINIENE v. vol. ii. p. 181.

QUININE C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>. [173° cor.] (Lenz, *Fr.* 27, 559; Hesse, *A.* 258, 133). The trihydrate melts at 57° (H.). S. 0.5 at 15° (Regnaud, *J. Pharm. Chim.* [4] 21, 8). S. (of the trihydrate) 0.6 at 15° (Hesse, *B.* 10, 2152); 0.6 at 20°, 1.1 at 100° (Sestini, *Fr.* 6, 359). S. (of the anhydrous base) 0.61 at 15° (H.); 0.7 at 20°, 1.3 at 100° (S.). S. (ether) 100 at 10° (Hesse, *A.* 135, 827); 4.4 at 18° (van der Burg, *J.* 1865, 438). A conc. ethereal solution often gelatinises, the quinine thus separated being less sol. ether (S. about 5 at 15°). S. (chloroform) 57.5 (Pettenkofer, *J.* 1858, 863). S. (benzene) 5 at 15°; 3.3 at 80° (Oudemans, *J.* 1874, 867). S. (xylene) 1.1 at 15°; 6.45 at 138° (Swaving, *R. T. C.* 4, 186). [α]<sub>D</sub> = -166° at 15°; -163°

at 26° in alcoholic solution (Hesse, *A.* 166, 217) = -145.2 + 657*p* in a solution of *p* grammes in 100 c.c. of 97*p.c.* alcohol at 15° (Hesse, *A.* 176, 206; 182, 181). [ $\alpha$ ]<sub>D</sub> = -158.7 + 1.911*p* in an ethereal solution containing from 1.5 to 6 *p.c.* base. In solutions containing not more than 1.6 *p.c.* quinine, Oudmans, jun. (*Ar. N.* 10, 193), found [ $\alpha$ ]<sub>D</sub> = -187.5° (in alcohol); -136° in benzene; -127° in toluene; -117° in chloroform. Dispersive power: Grimbirt, *J. Ph.* [5] 16, 295, 345.

**Occurrence.**—In cinchona bark, *v. vol.* ii. p. 175. According to Grimaux (*Bl.* [3] 7, 304), cupreine heated with NaOMe, MeOH, and MeCl or MeNO<sub>2</sub> yields 10 to 15 *p.c.* of quinine, while MeI gives chiefly quinine di-methylo-di-iodide.

**Preparation.**—The bark is extracted with dilute H<sub>2</sub>SO<sub>4</sub>, and the solution p.p.d. by NaOHaq. The pp. is dissolved in ether, the ether shaken with dilute H<sub>2</sub>SO<sub>4</sub>, and the boiling solution neutralised by ammonia. Quinine sulphate separates on cooling. The sulphate is decomposed by ammonia.

**References.**—*Vide* references in articles CINCHONA BARK and CINCHONIDINE, and also Pasteur, *C. R.* 36, 26; 37, 110, 162; Schützenberger, *A.* 108, 347, 350; Robiquet, *A. Ch.* [2] 17, 316; Stratingh, *R. P.* 15, 139; Pelletier, *J. Ph.* 11, 249; Duflos, *J. D.* 27, 1, 110; Strecker, *A.* 91, 155; Thiboumery, *J. Ph.* [3] 16, 369; Alluard, *J. Ph.* [3] 46, 192; Körner, *Z.* [2] 1, 150; Bouchardat, *A. Ch.* [3] 9, 213; De Vrij, *N. J. P.* 14, 268; Landrin, *C. R.* 103, 750.

**Properties.**—P.p.d. by ammonia from solutions of its salts in an amorphous anhydrous form, which quickly changes, especially in presence of free ammonia, into the crystalline hydrate (containing 3aq), consisting of minute four-sided prisms terminated by pyramids. The hydrate gives off its water of crystallisation over H<sub>2</sub>SO<sub>4</sub>. Quinine is *v. s.* sol. ether and alcohol, *v. sol.* CS<sub>2</sub>, *m. sol.* benzene, *v. sl. sol.* ligroin, *sol. volatile* and fixed oils. It is alkalinising in reaction. Its solutions are levorotatory. A 5 *p.c.* solution of the sulphate gives  $\alpha = -22^\circ$  in a depth of 200 mm. (Rozsnyay, *Fr.* 23, 589). Its solutions in dilute H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>, and HOAc exhibit blue fluorescence, destroyed by HCl, HBr, HI, or H<sub>2</sub>FeCy<sub>6</sub>. Fluorescence of the sulphate is prevented by a large excess of sulphate of cupreine (Grimaux, *a. Arnaud*, *Bl.* [3] 7, 304). Chlorine-water and ammonia give a green pp. dissolving in excess of ammonia to an emerald green liquid. On addition of an acid the colour changes through blue (when neutral) to red, the green colour returning on adding ammonia (Brandes, *Ar. Ph.* 13, 65; André, *J. Ph.* 22, 132). Excess of chlorine-water and of ammonia should be avoided. Chlorine does not render a solution of quinine sulphate turbid (Lepage, *J. Ph.* 26, 140). Bromine-water and ammonia give the green colour even in exceedingly dilute solutions (Flückiger, *Fr.* 11, 318). The green colour may be also got by mixing .01 g. of the salt to be tested with an equal bulk of KClO<sub>4</sub> and a drop of conc. H<sub>2</sub>SO<sub>4</sub>, followed by excess of ammonia (Mylus, *C. C.* 1886, 602). Chlorine-water followed by K<sub>2</sub>FeCy<sub>6</sub> gives a red colour in a solution of quinine sulphate (Vogel, *A.* 73, 221; 86, 122). Quinine gives the usual alkaloidal

reactions. It is coloured green by potash-fusion (Lenz, *Fr.* 25, 81). Potassium sulphocyanide gives a white pp., *sol.* excess (Schrage, *Ar. Ph.* [3] 13, 25). Boiled with dilute H<sub>2</sub>SO<sub>4</sub> and PbO<sub>2</sub>, quinine forms quinetin, a red substance (Marchand). Dilute HNO<sub>3</sub> gives no colour. Sunlight acting on an aqueous solution, even in an atmosphere of H<sub>2</sub>, ppts. brown flocculent quiniretin, *insol.* water, alcohol, and ether (Flückiger, *Ph.* [3] 8, 885). ICl gives a light-brown crystalline pp., *sl. sol.* HClAq. Quinine is antiseptic, hindering putrefaction and the alcoholic, lactic, and butyric fermentation. Quinine is a febrifuge. Its salts taste bitter.

**Reactions.**—1. The sulphate is oxidised by KMnO<sub>4</sub> to pyridine tricarboxylic acid, oxalic acid, and NH<sub>3</sub> (Hoogewerf, *a. van Dorp*, *B.* 12, 158). At 0° the first product is chitenine C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>, which crystallises in colourless prisms [240°-286°], *insol.* ether and alcohol, *sol.* dilute acids and alkalis (Skraup, *B.* 12, 1104; *M.* 10, 39). Quinine (5 g.) is apparently oxidised by KMnO<sub>4</sub> (50 g.) to pyridine dicarboxylic acid (Ramsay, *a. Dobbie*, *C. J.* 33, 102). Boiling nitric acid also forms pyridine dicarboxylic (cinchomeronic) acid. Aqueous CrO<sub>3</sub> oxidises quinine to quinoline or methoxyquinoline carboxylic acid.—2. A mixture of HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> reacts, and on diluting an amorphous pp., apparently C<sub>10</sub>H<sub>22</sub>(NO<sub>2</sub>)<sub>2</sub>N<sub>2</sub>O<sub>2</sub>H<sub>2</sub>O is got (Rennie, *C. J.* 39, 469).—3. PCl<sub>5</sub> converts it into colourless quinine-chloride C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>OCl [151°] which by boiling with alcoholic KOH gives chinen C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O (Comstock, *a. Königs*, *B.* 17, 1988).—4. Reduced by zinc and dilute H<sub>2</sub>SO<sub>4</sub> to hydroquinine C<sub>10</sub>H<sub>20</sub>N<sub>2</sub>O<sub>2</sub>, an amorphous bitter resin (containing aq), *sol.* alcohol and ether, giving a green colour with chlorine-water and ammonia (Schützenberger, *A.* 108, 347).—5. Heated with water at 250° it yields quinoline (Reynoso, *C. R.* 24, 795). The same body is formed by heating with conc. KOHAq at 190° (Gerhardt, *a. Wertheim*, *J.* 1840, 370).—6. Fuming H<sub>2</sub>SO<sub>4</sub> forms a sulphonic acid. Conc. H<sub>2</sub>SO<sub>4</sub> dissolves quinine, forming isocinchonine. Dilute H<sub>2</sub>SO<sub>4</sub> at 125° converts quinine into quinicine.—7. Iodic acid gives off much gas on warming (Brett, *J. Ph.* [3] 27, 116).—8. Conc. HClAq at 150° forms MeCl and apoquinine (Hesse, *A.* 205, 317). Concentrated HClAq at -17° slowly forms hydrochloroquinine C<sub>10</sub>H<sub>22</sub>ClN<sub>2</sub>O<sub>2</sub> [187°], while hydrogen bromide gives C<sub>10</sub>H<sub>22</sub>BrN<sub>2</sub>O<sub>2</sub>, which forms B'H<sub>2</sub>Br<sub>2</sub> (Comstock, *a. Königs*, *B.* 20, 2510).—9. Heated for a long time with 12 pts. of HIAq. S.G. 1.96 for 8 hours at 100° it gives methyl iodide and a yellow salt C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>III [238°] *sol.* alkalis. Alcoholic NH<sub>4</sub>Aq converts it into C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>2HI mixed with a little C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>HI, which yields an oxalate [187°] (C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>HI)H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> mixed with (C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>HI)<sub>2</sub>H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> (Schubert, *a. Skraup*, *M.* 12, 684). HBrAq acting on quinine at 100° forms C<sub>10</sub>H<sub>22</sub>BrN<sub>2</sub>O<sub>2</sub>HBr aq, crystallising in needles, from which sodium carbonate sets free C<sub>10</sub>H<sub>22</sub>BrN<sub>2</sub>O<sub>2</sub>, a powder [210°] (Julius, *M.* 6, 751). 10. Quinine dried at 120°, heated with HIAq (S.G. 1.7) at 100°, forms C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>3HI [230°], a yellow crystalline mass, *v. sl. sol.* water, *sl. sol.* alcohol, *insol.* ether and NaOHaq. Alcoholic NH<sub>3</sub> converts this salt into C<sub>10</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>HI which is white, *v. sol.* alcohol, *sl. sol.* ether [155°-

160°). Its solution in dilute  $H_2SO_4$  shows blue fluorescence, and gives a brownish-yellow pp. with chlorine-water and ammonia. It gives rise to the salts  $((C_{20}H_{21}N_3O_2)_2H_2I_2) \cdot 8H_2C_2O_4$ ? and  $C_{20}H_{21}N_3O_2 \cdot H_2LHNO_3$ ? [217°] (Schubert a. Skraup, *M.* 12, 678; cf. Lippmann a. Fleissner, *M.* 12, 329).—11. Bromine added to a solution of quinine in dilute  $H_2SO_4$  ppts.  $B'Br_2$  2aq,  $B'Br_3$ , and  $B'Br_4$ , as bitter yellow curdy pps., melting at 160°–180° (Colson, *C. R.* 108, 678).

**Estimation.**—V. CINCHONA BARK. V. also Lenz, *Fr.* 27, 549–631. Quinine may be ppd. as chromate (De Vrij, *C. C.* 1889, 708; *Ar. Ph.* [3] 24, 1073; Vulpinus, *Ar. Ph.* [3] 24, 1022; Schlikum, *Ar. Ph.* [3] 25, 128; Hesse, *Ph.* [3] 17, 586). A solution of quinine sulphate requires more ammonia to redissolve the pp. first formed than solutions of the sulphates of the alkaloids usually present with it (Kerner a. Weller, *Ar. Ph.* [3] 25, 712, 749; *Fr.* 1, 159; 27, 115; cf. Schäfer, *Ar. Ph.* [3] 25, 1033; Ruddiman, *C. N.* 58, 202, 216, 226; Jungfleisch, *J. Ph.* [5] 15, 5). Use may also be made of the sparing solubility of quinine oxalate in presence of  $K_2C_2O_4$  (Schäfer, *Ar. Ph.* [3] 25, 64, 1041).

**Constitution.**—Chitenine  $C_{18}H_{22}N_2O$  may be got by oxidation of both quinine and cinchonine. On further oxidation chitenine yields quinio, pyridine tricarboxylic, and cincholeuponic acids. From this it may be surmised that one half of the quinine molecule has the same composition as one half of the cinchonine molecule (Skraup, *M.* 10, 39, 220). Quinine, quinidine, and quinicine are probably stereo-isomeric, since they give the same products of oxidation; they are derivatives of (*B.* 2)-methoxy-quinoline while cinchonine is a derivative of quinoline. Cincholeuponic acid  $C_8H_7NO_4$  [226°] yields  $C_8H_7NO_4 \cdot HCl$  [194°] and  $C_8H_7NO_4 \cdot AcNO_2$ , and is converted by nitrous acid into the dibasic nitroso-derivative  $C_8H_6(NO)_2O$ . Oxidation of quinine also yields a base, cincholeupone  $C_8H_7NO_2$ , oxidised by  $CrO_3$  to cincholeuponic acid and other products. Cincholeupone when heated with zinc-dust yields (*B.* 2)-ethyl-pyridine. By nitrous acid cincholeupone is converted into  $C_8H_6(NO)_2O$ , which is an acid.  $Ac_2O$  forms acid  $C_8H_6Ac_2O_2$ . Oxy-quinoline (cynurine) is also a product of oxidation of quinine. From these experiments Skraup concludes that quinine and cinchonine contain a quinoline nucleus united to an ethyl-pyridine nucleus; quinine being methoxy-cinchonine. Cupreine heated with  $NaOMe$  (1 mol.),  $MeI$  (6 mols.), and  $MeOH$  forms quinine di-methylo-di-iodide (Hesse, *A.* 266, 244; cf. Grimaux a. Arnaud, *C. R.* 112, 774; *A.* 267, 379). The chief product is, however, cupreine mono-methylo-iodide. When only 1 mol.  $MeI$  is used, no quinine is got.

**Salts.**— $C_{20}H_{21}AgN_3O_2$ . Gelatinous pp. got by adding  $AgNO_3$  to a solution of quinine in alcoholic  $NH_3$  (Skraup, *M.* 2, 613).— $B'HCl$  2aq: groups of white needles (Hesse, *A.* 176, 210; 267, 142). Melts (when anhydrous) at 160°, without undergoing any change.  $S. 2.5$  at 10°.  $V. e.$  sol. alcohol and ether.  $[a]_D = -134^\circ$  in a 2 p.c. solution at 17° (Oudemans). Its solution is not ppd. by silver nitrate (1 mol.) until added in excess (Vulpinus, *Ar. Ph.* [3] 20, 361).— $B'HCl$  1½aq. Large monoclinic octahedra, deposited at 0°.— $B'2HCl$ . Groups of white needles,

or gelatinous mass.  $S. 100$  in the cold. Melts at 15° (A. Clermont, *J. Ph.* [5] 15, 15).— $B'H.PtCl_5$  aq: yellowish flocculent pp., soon becoming orange and crystalline (Gerhardt, *B. J.* 23, 354).  $S. 0.7$  in the cold; 8 at 100° (Duflos).— $B'H_2PtCl_3$  3aq: orange amorphous pp. (Hesse, *A.* 207, 308).— $B'H_2HgCl_4$ . Ppd. by mixing alcoholic solutions of quinine,  $HCl$ , and  $HgCl_2$  (Hinterberger, *A.* 77, 201).— $B'H_2ZnCl_2$  2aq: prisms (from alcohol) (Gräffinghoff, *Bl.* [2] 4, 391).— $B'H_2ZnCl_2$  3aq: crystalline.— $B'H_2Br_3$  3aq: crystals,  $v. e.$  sol. water.— $B'HI$ : lemon-yellow prisms (Herapath), or heavy white powder.  $Sl.$  sol. water,  $v. e.$  sol. alcohol (Winckler, *Jahrb. pr. Pharm.* 20, 321). Melts at 150°–155°, but softens at about 100° and then blackens (Lippmann a. Fleissner, *M.* 13, 436).— $B'HIET_2O$  (from ether). Crystals.— $B'HI_2$  5aq (Regnault). Crystals. *V. Reaction 9, supra.*— $B'HI_2$  [230°]. Converted by  $NH_3$  aq into  $BHI$ .— $B'H_2SO_4$  8aq (Hesse, *A.* 119, 361; 225, 97; Carles, *Bl.* [3] 7, 108; cf. Cowley, *Ph.* [3] 7, 189). Commercial specimens are somewhat effloresced. Monoclinic efflorescent prisms. Loses 6aq over  $H_2SO_4$ .  $S.$  (of  $B'_2H_2SO_4$ ) 126 at 6°; 3 at 100° (Howard).  $S.$  (alcohol of  $S.G. .85$ ) 1.  $S.$  (glycerin) 2.5. Insol. chloroform and fatty oils.  $[a]_D = -163^\circ$  in a 2 p.c. solution in 80 p.c. alcohol.— $B'H_2SO_4$  7aq. [100°]. Rectangular prisms (from hot solutions) or small needles.  $S.$  9 at 13°; 12.5 at 22°. Loses 6aq over  $H_2SO_4$ .  $[a]_D = -164.9 + 31p$  in a solution of  $p$  g. in 100 c.c. water, where  $p$  is between 1 and 6 (Hesse, *A.* 176, 215; 182, 134).— $B'(H_2SO_4)_2$  7aq: prisms,  $v. e.$  sol. water,  $m.$  sol. alcohol. Its hot alcoholic solution deposits gelatinous  $B'(H_2SO_4)_2$  5aq.  $[a]_D = -170 + 94p$ .— $B'_2H_2Cl_2H_2SO_4$  3aq. Mass of small needles,  $v.$  sol. water.  $S.$  (of anhydrous salt) 86. [120°] (hydrated); [165°–170°] (anhydrous) (Grimaux, *Bl.* [3] 7, 819).— $B'_2H_2Br_2H_2SO_4$  3aq.  $S.$  26 at 21°.— $B'_2H_2I_2H_2SO_4$  2aq: yellow crystals, forming a colourless solution. Crystallises also with 4aq.— $B'_2H_2Cl_2H_2PO_4$  9aq: small needles,  $sl.$  water.— $B'_2H_2Br_2H_2PO_4$  7aq.— $B'_2H_2I_2H_2PO_4$  6aq.— $B'_2H_2SO_4$  2aq.  $S.$  3 (Vetherill, *A.* 66, 150; How, *N. Ed. P. J.* [2] 1, 47).— $B'HNO_3$  aq: prisms (Strecker, *A.* 91, 159).— $B'AgNO_3$  3aq: crystalline pp. Chlorate.— $B'HIIO_3$  2aq (Tichborne, *Z.* 1866, 665; cf. Serullas, *A. Ch.* [2] 45, 279).— $B'(HClO_4)_2$  7aq: trimetric octahedra.— $B'(HClO_4)_2$  2aq. [210°] (Boedeker, *A.* 71, 61).— $B'HIIO_3$  9aq: needles (Langlois, *A. Ch.* [3] 31, 274).— $B'(HCl)_3(HI)_2$ : small brown crystals.— $B'_3(HCl)_3(HI)_2$ : blackish-green flat needles (Jörgensen, *J. pr.* [2] 15, 79).— $B'HI_2$  (Bauer, *Ar. Ph.* [3] 5, 214).— $B'HI_2$ . Black prisms.— $B'_2I_2$ . Resin.— $B'_2I_2$ .— $B'_2(H_2SO_4)_2(HI)_2$  6aq. *Herapathite*. Formed by adding an alcoholic solution of iodine to a solution of quinine sulphate in  $HOAc$  (Herapath, *P. M.* [4] 3, 161; *J.* 186; 6, 171, 346; 7, 352; 9, 366; 14, 224; *C. J.* 11, 130; Haidinger a. Stokes, *Sitz. W.* 10, 106; Jörgensen, *J. pr.* [2] 14, 230). Large colourless plates with metallic green lustre. Polarises light, so that two plates at right angles are opaque.  $S.$  (90 p.c. alcohol) 125 at 16°. Decomposed by cold water. Dried over  $H_2SO_4$ , they become  $B'(H_2SO_4)_2I_2$  3aq (Hauer, *Z.* [2] 1, 481).— $B'_2(H_2SO_4)_2(HI)_2$ : thin lustrous plates.— $B'_2(H_2SO_4)_2(HI)_2$  2aq. Crystals, resembling herapathite, decomposed by hot alcohol into

iodine and herapathite. —  $B'_2(H_2SO_4)(HI)_4$ , 4aq. brownish needles. —  $B'_2H_2SO_4(HI)_4$ : red needles. —  $B'_2H_2SO_4(HI)_4$ : brown rectangular plates with olive-green reflex. —  $B'_2H_2SO_4(HI)_4$ : black crystals with green reflex. —  $B'_2(H_2SO_4)_2(HI)_4$ . —  $B'_2(H_2SO_4)_2(HI)_4$ , aq. —  $B'_2(H_2SO_4)_2(HI)_4$ . —  $B'_2H_2SeO_4$ , 7aq: trimetric tables, insol. alcohol (Hjortdahl, *J.* 1879, 794). —  $B'_2(H_2SeO_4)_2(HI)_4$ . Isomorphous with herapathite, which it greatly resembles. Almost insol. cold alcohol (Jörgensen, *J. pr.* [2] 15, 65, 418). —  $B'_2H_2CrO_4$ . S. -0.42 at 15° (André); -0.37 at 14°; -0.5 at 16° (De Vrij, *Ar. Ph.* [3] 24, 1073; -625 at 100° (A.). Ppd. by adding  $K_2CrO_4$  to a solution of the neutral or acid sulphate. Tufts of golden needles. —  $B'_2H_2CrO_4$ , 2aq (Hesse, *Ph.* [3] 17, 585, 665). Becomes anhydrous at 80°, but re-absorbs 2aq on exposure to moist air. —  $B'_2H_2CrO_4$ , 7aq. Ppd. by adding  $K_2CrO_4$  to a solution of quinine in excess of dilute  $H_2SO_4$  (André, *J. Ph.* [3] 41, 341). Orange pp., decomposed by light, and turned brown when heated to 60°-65° or when boiled with water. More soluble than  $B'_2H_2CrO_4$ . —  $B'_2H_2CO_3$ , aq. Efflorescent needles, with alkaline reaction, deposited from a solution of quinine in aqueous  $CO_2$ . Sol. alcohol, insol. ether (Langlois, *A. Ch.* [3] 41, 89). —  $B'_2H_2PO_4$ , 8aq. S. -127 at 10° (Hesse). Tufts of long needles. —  $B'_2H_2PO_4$ , 5aq (Anderson, *A.* 66, 59). Crystals. —  $B'_2H_2PO_4$ , 12aq (A.). —  $B'_2H_2PO_4$ , 2aq (Gerhardt, *Gerh.* iv. 118). —  $B'_2H_2PO_4$ . S. 1:33 at 15.5° (L. Smith, *Z.* 1862, 159). —  $B'_2HVO_4$  (Ditte, *A. Ch.* [6] 13, 236). —  $B'_2HSiF_6$ . Got by passing  $SiF_4$  into a solution of quinine in absolute alcohol (Cavazzi, *G.* 17, 563). Minute crystals, insol. ether and  $CS_2$ , sl. sol. hot alcohol. Its aqueous solution is fluorescent. —  $B'_2H_2AsO_4$ , 8aq. Prisms, v. sol. hot water (Hesse). —  $B'_2H_2AsO_4$ , 6aq (Sestini). —  $B'_2H_2AsO_4$ , 2aq. —  $B'_2H_2FeCy_4$ , 3aq (Dollfus, *A.* 65, 227). —  $B'_2H_2FeCy_4$ , 1aq: golden plates. —  $B'_2H_2PtCy_4$ , aq (Wertheim, *A.* 73, 210). Crystals. —  $B'_2H_2PtCy_4$ , 2aq. S. -0.54 at 18°; 1:8 at 57°. S. (alcohol) 20 at 16° (Schwarzenbach, *Pharm. Viertelj.* 8, 210; Van der Burg, *Fr.* 4, 312). —  $B'_2H_2PtCy_4$ , 2aq. -0.74 at 18.5°; 5 at 100°. —  $B'_2H_2PtCy_4$ . —  $B'_2HCyS$ . Lemon-yellow monoclinic crystals (W.). —  $B'_2HCyS$ , aq. S. -18 at 20° (Hesse, *A.* 181, 48). —  $B'_2(HCyS)_4HgCl_2$ . —  $B'_2(HCyS)_4HgCy_2$ . —  $B'_2(HCr(CyS)_3(NH_3)_3)_2$ , 2aq. Formed by ppg. a solution of the acid sulphate with Reinecke's salt (Christensen, *J. pr.* [2] 45, 366). Red crystals, v. sl. sol. hot water. — Nitro-prusside. S. -04 (Davy, *Ph.* [3] 11, 756). — Cyanurates  $B'_2HCN_3O_9$ , 2aq. [237°]. Sl. sol. hot water (Claus, *J. pr.* [2] 38, 227). —  $B'_2(H_2CN_3O_9)_2$ , 7aq. [213°]. — Oxalates. —  $B'_2H_2C_2O_4$ , 6aq. S. -1 at 10°. Prisms (Hesse, *A.* 176, 218; cf. Regnault, *A.* 26, 37). —  $B'_2H_2C_2O_4$ , aq. Prisms, m. sol. cold water. —  $B'_2H_2C_2O_4$ , 3aq. [α] = -13°. —  $B'_2HOAc$ . [140°]. Long needles, v. sol. hot water (R.). —  $B'_2Cu(OAc)_2$ . Green crystals (Skraup, *M.* 2, 611). — Chloro-acetate  $B'_2H_2ClO_4$ , 2aq. S. 1:6 at 21° (Mazzara, *G.* 13, 525). — Di-chloro-acetate  $B'_2H_2Cl_2O_4$ , 2aq. S. 2:4 at 22°. — Formate: colourless needles (Bonaparte, *J. Chim. Méd.* 18, 680). — Valerate  $B'_2H_2H_3O_4$ , 1aq (Bonaparte, *J. Chim. Méd.* 18, 680; 19, 330; Chatin, *J. Ph.* [4] 1, 268). —  $B'_2C_6H_5O_4$  (Stalman, *A.* 147, 132; Schmidt a. Sachtleben, *A.* 193, 100). S. -9 in the cold; 2:5 at 100° (Wittstein, *Report.* 87, 295; Landerer,

*N. Br. Arch.* 119, 240). — Succinate  $B'_2C_4H_4O_8$ , 8aq. S. -1 at 10°. Prisms, v. sol. hot water. — Tartrate  $B'_2C_4H_4O_8$ , 2aq. Crystalline powder (Hesse, *A.* 243, 134; cf. Arppo, *J. pr.* 53, 334). —  $B'_2C_4H_4O_8$ , aq (Pasteur, *J.* 1853, 421). The laevo-tartrate is more soluble than the dextro-tartrate, and has a different crystalline form. —  $B'_2C_4H_4(SbOH)_4O_8$ , 2aq. Resin (Clarke, *B.* 15, 1540). — Citrate  $B'_2C_6H_8O_7$ , 7aq. S. -11 at 12° (Hesse); 44 at 100° (Mandelin, *J.* 1879, 796; Scribani, *G.* 9, 284). —  $B'_2C_2C_4H_4O_8$ : minute prisms. S. -11 in the cold; 2:4 at 100°. —  $B'_2C_6H_4O_8$ . Small prisms. S. -16 in the cold, 2:6 at 100°. — Chloro-crotonate  $B'_2C_8H_8ClO_4$ . [201°]. Sl. sol. ether (Dacomo, *J.* 1884, 1385). — Trichlorocrotonate  $B'_2C_8H_8Cl_3O_4$ . [140°]. — Tri-chloro-lactate  $B'_2C_8H_8Cl_3O_4$ . Sl. sol. ether. — Di-bromo-pyruvate  $B'_2C_4H_4Br_2O_4$ . [93°] (D.). — Mucate  $B'_2C_6H_8O_7$ . Needles (Ruhemann, *Dafton, C. J.* 59, 754). — Benzoate  $B'_2HOBz$ . S. -27 at 10°. Small prisms. — Salicylate  $B'_2C_7H_7O_4$ . S. -44 at 16°. S. (ether) -83 at 16°. Prisms (from alcohol). — Melitate  $B'_2C_8H_8O_6$ . Crystalline powder, v. sl. sol. cold water (Karmrod, *A.* 81, 170). — Tannate  $B'_2(C_6H_5O)_4$ , 4aq and  $B'_2(C_6H_5O)_4$ , 8aq (Jobst, *Ar. Ph.* [3] 12, 331; Neumann, *Fr.* 28, 664). — Meconate  $B'_2C_8H_8O_4$ . Crystals (Austen, *Ph.* [3] 3, 1016). — Urate  $B'_2C_8H_8N_2O_4$ . Minute prisms. S. -117 in the cold, 2:7 at 100°. S. (alcohol of S.G. -823) -0.63 in the cold, 2:2 on boiling (Elderhorst, *A.* 74, 77; Andrew, *Pharm. Viertelj.* 10, 382). Dextro-tropate. [187°]. — Lævo-tropate. [178°] (Ladenburg, *B.* 22, 2590). Dextro-iso-propyl-phenyl-glycolate [193°]. S. -18 at 19°; S. (alcohol) 1:44 at 20°. [α]<sub>D</sub> = -79°. — Lævo-iso-propyl-phenyl-glycolate [205°]. S. -0.9 at 15°; S. (alcohol) 5:1. [α]<sub>D</sub> = -118° (Filleti, *J. pr.* [2] 46, 560). Compound with benzene  $B'_2C_6H_6$ . Needles (from benzene) (Oudemans, *J.* 1874, 867). — Compound with toluene  $B'_2C_7H_8$ . Needles. — Compounds with phenol  $B'_2PhOH$ . Crystals (from alcohol). S. -25 at 16° (Romei, *Z.* [2] 5, 383; Jobst, *N. R. P.* 24, 193). —  $B'_2H_2Cl_2PhOH$ , 2aq: prisms. S. 1:15 at 15° (Jobst a. Hesse, *A.* 180, 248). —  $B'_2H_2SO_4PhOH$ , 2aq (Hesse, *Pharm. Zeit.* 34, 191). —  $B'_2H_2SO_4PhOH$ , aq. S. -147 at 15°. Prisms. —  $B'_2H_2SO_4PhOH$ , 6aq (Cotton, *Bl.* [2] 24, 535). — Compound with tri-bromo-phenol  $B'_2C_6H_3Br_3O_4$ . Silky needles (from alcohol) (Purgotti, *G.* 16, 528). — Compound with anethole  $B'_2C_9H_8O_4$ , 2aq. Monoclinic crystals (from ether), sl. sol. cold alcohol (Hesse, *A.* 123, 332). — Compound with eugenol  $B'_2C_{10}H_{12}O_4$ . [110°]. S. (ether) 8:5 at 10°. Long silky prisms (Hesse, *A.* 135, 329). — Compound with pyrocatechin  $B'_2C_8H_6O_4H_2SO_4$ , aq: colourless needles (Hesse, *C.* 1889, 519). — Compounds with resorcin  $B'_2C_8H_6O_4H_2SO_4$ , aq: needles (Malin, *A.* 138, 77). —  $B'_2C_6H_5O_4H_2SO_4$ , aq (Hesse). — Compound with phloroglucin  $B'_2C_6H_3O_4H_2SO_4$ , aq: stellate groups of needles (Hlasiwetz, *Z.* [3] 1, 618). — Compound with orcin  $B'_2C_8H_6O_4H_2SO_4$ , aq. Needles (Hlasiwetz a. Barth, *A.* 134, 290; 138, 77). — Compound with chloral  $B'_2C_2H_3ClO_4$ . [149°]. Amorphous, sl. sol. cold alcohol (Mazzara, *G.* 13, 270). — Compound with *m*-nitrobenzoic aldehyde  $B'_2C_8H_7(NO_2)CHO$ . [113°-118°]. Yellow powder (Mazzara, *G.* 13, 368). —

**Compound with nitro-camphor**  $B'(C_{10}H_{19}(NO_2)O)_2$  aq. Needles.  $[\alpha]_D = +46^\circ$  in a 2-7 p.c. alcoholic solution (Cazeneuve, *Bl.* [2] 49, 97).—**Compound with urea**  $B'C_{10}H_{19}H_2Cl_2$  5aq. S. 6. Small prisms (Drygin, *C. Ö.* 1878, 622; 1881, 245).—**Compounds with quinidine**  $B'C_{20}H_{33}N_3O_2$  2aq.— $B'C_{20}H_{33}N_3O_2$  3aq.— $B'C_{20}H_{33}N_3O_2O_2C_2H_5$  2aq (Wood a. Barret, *C. N.* 45, 6; 48, 4; Hesse, A. 243, 146).—**Compound with hydroquinidine**  $B'C_{20}H_{33}N_3O_2$  2aq: slender white needles, v. sl. sol. water, m. sol. ether.—**Compounds with cinchonidine**  $B'2C_{20}H_{33}N_3O_2$ . Rhombohedra, very slightly sol. ether (Hesse, A. 243, 131).— $B'7C_{10}H_{19}N_3O_2$ . Crystals (from alcohol).— $B'_{1/2}(C_{10}H_{19}N_3O_2)(H_2SO_4)$  20aq. S. 597 at  $15^\circ$ . Needles.— $B'_{1/2}(C_{10}H_{19}N_3O_2)(C_2H_5O_2)$  6aq.— $B'_{1/2}(C_{10}H_{19}N_3O_2)(H_2CrO_4)$  18aq: crystals.— $B'_{1/2}(C_{10}H_{19}N_3O_2)(H_2C_2O_4)$  6aq (?). Long colourless needles.—**Compounds with cupreine**  $B'C_{10}H_{19}N_3O_2$  4aq.  $[\alpha]_D = -236^\circ$ . Trimetric prisms (Howard a. Hodgkin, *C. J.* 41, 66; Hesse, A. 225, 98; 226, 242; 230, 72). Its solution in dilute  $H_2SO_4$  shows blue fluorescence.— $B'C_{10}H_{19}N_3OH$   $PtCl_4$  2aq: orange-red prisms.— $B'C_{10}H_{19}N_3OH_2SO_4$  6aq: six-sided prisms. S. 3 at  $100^\circ$ .— $B'C_{10}H_{19}N_3OC_2H_5O_2$  2aq: needles.

**Acetyl derivative**  $C_{20}H_{33}AcN_3O_2$ .  $[\alpha]_D = 108^\circ$ . Formed by heating quinine with  $Ac_2O$  (Hesse, A. 205, 317). Prisms, sol. alcohol and chloroform, sl. sol. ether.  $[\alpha]_D = -54^\circ$  in a 2 p.c. solution in alcohol (of 97 p.c.) at  $15^\circ$ .  $[\alpha]_D = -115^\circ$  in presence of 3HCl. Decomposed by alcoholic potash into quinine and  $HOAc$ .— $B'1/2PtCl_4$  2aq.— $B'(HAuCl_4)_2$  aq: yellow flocculent pp.

**Propionyl derivative**  $C_{20}H_{33}(C_2H_5O)_2N_3O_2$ .  $[\alpha]_D = 129^\circ$ . Six-sided prisms, sol. ether and alcohol.  $[\alpha]_D = -109^\circ$  in a 2 p.c. solution at  $15^\circ$  (Hesse).— $B'1/2PtCl_4$  2aq.— $B'(HAuCl_4)_2$  2aq: yellow amorphous pp.

**Benzoyl derivative**  $C_{20}H_{33}BzN_3O_2$ . Amorphous (Schützenberger, *C. R.* 47, 334).— $B'H_2PtCl_4$ .

**Methylo-iodide**  $B'MeI$  aq or  $C_{10}H_{19}(OMe)N_3C_2H_5NMeIO$  (Grimaux, *Bl.* [3] 7, 573).  $[233^\circ-236^\circ]$ . Formed by boiling quinine (1 mol.) with  $MeI$  (6 mols.) in  $MeOH$  (Strecker, *d.* 91, 164; Claus a. Mallmann, *B.* 14, 76). Formed also from cupreine,  $NaOEt$  and  $MeI$  (Hesse, A. 266, 240). Colourless needles (from water), v. sol. hot water and alcohol. Not attacked by alkalis in the cold. Boiling  $KOH$  aq or moist  $Ag_2O$  converts it into methyl-quinine  $C_{20}H_{33}MeN_3O_2$ , an oil which yields an amorphous hydroiodide, crystalline  $B'H_2PtCl_4$  aq (Hesse) or  $B'H_2PtCl_4$  2aq (Lippmann, *M.* 12, 512), and  $C_{20}H_{33}MeN_3O_2MeI$  aq crystallising in needles, decomposed at  $218^\circ$ .

**Methylo-periodides**  $B'MeI_2$ . Black needles (Jørgensen, *J. pr.* [2] 3, 145; 14, 261).— $B'_2MeI_2H_2SO_4$ . Reddish-brown needles (from alcohol).— $B'_2MeI_2H_2SO_4$ . Brown plates.— $B'_2MeI_22H_2SO_4$ . Almost black laminae.— $B'_2MeI_22H_2SO_4$ . Almost black needles with green lustre.

**Methylo-chloride**  $B'MeCl$  aq.  $[182^\circ]$ . Needles.— $B'_2MeH_2PtCl_4$ : orange prisms.

**Methylo-bromide**  $B'MeBr$  aq.  $[126^\circ]$ . Slender needles, sl. sol. cold water.

**Di-methylo-di-iodide**  $B'Me_2I_2$  3aq.  $[158^\circ-162^\circ]$ . Formed by heating  $B'MeI$  with

$MeI$  and  $MeOH$  in sealed tubes at  $100^\circ$ . Got also, together with  $B'MeI$  from cupreine by the action of  $NaOMe$  followed by  $MeI$  (Hesse, A. 266, 240). Yellow tables (from water). Converted by cold  $NaOHAq$ , or better  $NaOH$  in  $MeOH$ , into a resin and a smaller quantity of a yellow crystalline body. S. (boiling  $MeOH$ )  $1$ , melting about  $280^\circ$ , sol. acids and reppd. by alkalis as a jelly. Its solutions are yellow with green fluorescence. A similar body is got by the action of alkalis on the methylo-iodide of methoxy-quinoline (obtained from quinine).— $B'Me_2PtCl_4$  2aq.— $B'2MeAuCl_4$ .

**Ethylo-iodide**  $B'EtI$  aq (Howard, *C. J.* 26, 1180).  $[211^\circ]$ . Trimetric needles (from ether), with very bitter taste. Lævorotatory.— $B'EtI_2$ : black needles.

**Ethylo-chloride**  $B'EtCl$  3aq. Slender needles.— $B'EtH_2PtCl_4$ : yellow pp.

**Ethylo-bromide**  $B'EtBr$  2aq.

**Ethylo-sulphates**  $B'Et_2SO_4$  8aq.— $B'EtHSO_4$  2aq: needles, v. e. sol. water.

**Ethylo-cyanide**  $B'EtCN$ .  $[90^\circ]$ . White needles (Claus a. Merck, *B.* 16, 2746).

**Di-ethylo-di-iodide**  $B'Et_2I_2$  3aq.  $[115^\circ]$ . Prepared by heating quinine with  $EtI$  and alcoholic potash (Skraup, *M.* 2, 610). Monoclinic tables, sol. alcohol, insol. ether.

**Methylo-ethylo-di-iodide**  $B'MeEtI_2$  aq.  $[208^\circ]$ . Formed by boiling  $B'MeI$  with  $EtI$  and alcohol (Claus, *B.* 14, 76). An isomeride  $[157^\circ-160^\circ]$  is got from  $B'EtI$  and  $MeI$ .

**Benzoylo-chloride**  $B'C_6H_5Cl$ . Amorphous.  $B'(C_6H_5)H_2PtCl_4$  2aq: crystalline (Mazzara, *G.* 13, 530).— $B'(C_6H_5)_2PtCl_4$ : yellow powder.

**Tolylo-quinine**  $C_{20}H_{33}(C_6H_5)_2N_3O_2$ . Two modifications are formed by heating quinine with  $o$ -toluidine, and two from  $p$ -toluidine. The  $o$  and  $p$  ( $\alpha$ ) modifications form oils soluble in ether; the  $o$  and  $p$  ( $\beta$ ) modifications form amorphous yellow powders insoluble in ether, soluble in chloroform and alcohol.  $B'1/2PtCl_4$  aq: yellow crystalline powders (Claus a. Bottler, *B.* 14, 80).

**Quinopropylene**  $C_{24}H_{39}N_3O_2$ .  $[164^\circ]$ . Got by heating sodium-cupreine with  $PrNO_3$  and  $PrOH$  at  $110^\circ$  (Grimaux a. Arnaud, *Bl.* [3] 7, 310). White powder.— $B'H_2SO_4$   $1\frac{1}{2}$  aq. Silky needles.  $[224^\circ]$ .  $[\alpha]_D = 229$  at  $22^\circ$ .

**Quinoisopropylene**  $[151^\circ]$ . Formed in like manner from  $PrNO_3$ .— $B'H_2SO_4$  aq. S. 3 at  $10^\circ$ .  $[\alpha]_D = 229^\circ$ .

**Quinoamyline**  $C_{23}H_{31}N_3O_2$ .  $[167^\circ]$ . Formed from sodium-cupreine and amyl chloride in amyl alcohol at  $105^\circ$ . Amorphous.— $B'H_2SO_4$  2aq. Needles. S. 025 at  $11^\circ$ . Its solution in dilute  $H_2SO_4$  fluoresces.

**Quinine sulphonic acid**  $C_{20}H_{33}(SO_3H)N_3O_2$ .  $[209^\circ]$ . Formed by moistening quinine tetrasulphate with  $Ac_2O$ , and treating the product with hot water (Hesse, A. 267, 141). Small white prisms (containing aq when air-dried).  $[\alpha]_D = -182^\circ$  in a 2 p.c. solution containing  $HCl$  (3 mols.).— $H_2A_2H_2PtCl_4$  8aq.

**Quinine (iso)-sulphonic acid**  $C_{20}H_{33}N_3O_2(SO_3H)$ . Formed from quinine and fuming  $H_2SO_4$  (Hesse, A. 267, 138). V. sol. water, forming a slightly acid lævorotatory solution with blue fluorescence. Gives a dark-green colour with chlorine-water and  $NH_4Aq$ .— $HA_2HAuCl_4$ : yellow flocculent pp.

**Apoquinine**  $C_{19}H_{21}N_3O_2$ . [160°].  $[\alpha]_D = -178^\circ$  in a 2 p.c. solution of alcohol (of 97 p.c.) at 15°.  $[\alpha]_D = -247^\circ$  in water containing 3HCl. Formed by heating quinine or cupreine with HClAq at 140° (Hesse, A. 205, 323, 341; 230, 65). Amorphous powder (containing 2aq), sol. alcohol, ether,  $CHCl_3$ , and hot water. A solution of its sulphate shows no fluorescence. Chlorine-water and ammonia give a dark-green colour in the cold. The alcoholic solution gives a dark brownish-red colour with  $FeCl_3$ . Fuming HClAq at 150° forms  $C_{19}H_{21}ClN_3O_2$  2aq [160°], which gives the salts  $B'H_2Cl$  3aq,  $B'H_2PtCl_2$  2aq, and  $C_{19}H_{21}Ac_2ClN_3O_2$  [184°].

**Salts.**— $B'H_2PtCl_2$  3aq. — $B'HI$ . Small crystals (Lippmann a. Fleissner, M. 12, 331).

**Acetyl derivative**  $C_{19}H_{21}AcN_3O_2$ : amorphous powder, sol. ether and alcohol.

**Isoapoquinine**  $C_{19}H_{21}N_3O_2$ . [176°]. Formed by the action of boiling alcoholic potash on  $C_{19}H_{21}N_3O_2 \cdot 3HI$  [238°] (v. QUININE, Reaction 8). Crystalline (Lippmann a. Fleissner, M. 12, 331). — $B'H_2PtCl_2$  aq: granules, sl. sol. water.

**Isoquinine**  $C_{20}H_{23}N_3O_2$ . [186°].  $[\alpha]_D = -181^\circ$  in a 4 p.c. solution. Formed from the compound  $C_{20}H_{23}N_3O_2 \cdot 3HI$  [230°] (v. QUININE, Reaction 9) with alcoholic potash (Lippmann a. Fleissner, M. 12, 332). Needles (containing aq), v. e. sol. benzene, sl. sol. ether, v. sl. sol. boiling water. Coloured green by chlorine-water and ammonia. — $B'HI$  2aq: needles, v. sol. water. — $B'2HCl$ , m. sol. water. — $B'2PtCl_2$ : yellow crystalline pp. — $B'H_2SO_4$  10aq: needles, v. e. sol. water. — $B'AgNO_3$ : needles.

**ψ-Quinine**  $C_{20}H_{23}N_3O_2$ . [191°]. Formed, together with nichine  $C_{19}H_{21}N_3O_2$  (?), by heating quinine hydroiodide with alcoholic potash (Skrapp, B. 25, 2911). Laborotatory. Yields  $B'HI$ ,  $B'HNO_3$ , and  $B'HNO_3$ , all sl. sol. water and readily crystallised.

**Chinene or Quinene** v. QUINIENE, vol. ii. p. 181.

**Homokinine** v. CINCHONA BASES.

**QUININIC ACID** v. Methyl derivative of (B. 3)-OXY-QUINOLINE CARBOXYLIC ACID.

**QUINISATIC ACID**  $C_8H_7(NH_2) \cdot CO \cdot CO \cdot CO_2H$ . o-Amido-benzoyl-glyoxylic acid. Formed by oxidation of (Py. 1,2,3)-tri-oxy-quinoline with  $FeCl_3$  (Baeyer a. Homolka, B. 16, 2219). Yellow prisms, v. sol. water. On reduction with zinc dust and HOAc and exposure of the filtrate to the air it forms a dark-blue colouring matter.

**Anhydride**  $C_8H_5 \begin{smallmatrix} \diagup CO \cdot CO \\ \diagdown NH \cdot CO \end{smallmatrix}$ . [255°–260°].

Formed by heating the acid at 120°. Red crystals, forming a red solution in alcohol. Readily combines with water, with re-formation of the acid. Dilute NaOHaq forms a yellow solution, very quickly becoming colourless. NaOEt gives a body crystallising in indigo-blue needles. Gives an oxim  $C_8H_5 \begin{smallmatrix} \diagup CO \cdot C(NOH) \\ \diagdown N = C \cdot OH \end{smallmatrix}$  crystallising in orange prisms [208°].

**QUINTANNIC ACID.** An acid occurring in cinchona bark (Schwarz, J. pr. 56, 76; cf. Pelletier a. Caventou, A. Ch. [3] 15, 837). Hygroscopic yellow mass. Its alkaline solutions absorb oxygen. Converted by boiling dilute acids into glucose and a brownish-red powder  $C_{22}H_{22}O_{11}$ , which gives acetic and protocatechuic acid when fused with potash (Rembold, A. 143, 270).

**QUINITE**  $C_8H_7O_2$ , *l.e.*

$CH(OH) \begin{smallmatrix} \diagup CH_2 \cdot CH_2 \\ \diagdown CH_2 \cdot CH_2 \end{smallmatrix} CH(OH)$ . *Hydroquinone*

*hexahydride*. Formed, by reduction with sodium-amalgam in a current of  $CO_2$  from the product of the action of dilute  $H_2SO_4$  on the dihydride of di-oxy-terephthalic ether (succinyl-succinic ether) (Baeyer, B. 25, 1037, 1840). V. sol. water and alcohol. Occurs in two modifications, *trans* [144°] and *cis* [90°], which yield acetyl derivatives melting at 106° (*trans*) and 82° (*cis*). Both acetyl derivatives boil at 244°. Quinite is converted by HBr into di-bromo-benzene hexahydride (*trans* [114°], *cis* an oil), which on heating with quinoline gives oily benzene dihydride (81°), which forms a tetrabromide [182°].

**QUINIZARIN** v. DI-OXY-ANTHRAQUINONE.

**QUINIZINE.** Substances supposed to be derived from the hypothetical quinzine were subsequently found to be derivatives of phenylpyrazole. Thus oxy-methyl-quinizine is oxy-phenyl-methyl-pyrazole (*q. v.*).

**QUINOL** v. HYDROQUINONE.

**QUINOLIC ACID**  $C_8H_7N_3O_4$ . •Got by oxidation of cinchonine with  $HNO_3$  (Weidel, A. 173, 91; B. 12, 1152). Woolly crystals, almost insol. water, v. sl. sol. alcohol, sol. HClAq. Alkalies give a transient crimson colour. Br and water at 180° give hexa-bromo-quinoline.  $HNO_3$  at 170° forms cinchoneronic acid.— $AgA'$ . — $HA'HCl$ . — $H_2A'$ .  $H_2PtCl_2$ : orange needles.

**QUINOLINE**  $C_8H_7N$  *l.e.*

$CH \cdot CH \cdot C \cdot CH \cdot CH$ . *Chinoline*. *Leuconine*. Mol.  $CH \cdot CH \cdot C \cdot N \cdot CH$ . w. 129. (237°5') (Young, C. J. 55, 485); (234°) (Schiff, B. 19, 566); (241° cor.) (Kretschy, M. 2, 80). S.G.  $\approx 1.106$  (O. de Coninck, Bl. [2] 37, 208);  $\approx 1.108$  (Skrapp). S.V. 139.8 (Schiff). Vapour-pressure: Young. Heat of neutralisation: Colson, A. Ch. [6] 19, 409. Absorption of ultra-violet spectrum: Hartley, C. J. 41, 47. Occurs in coal-tar (Runge, P. 31, 68; Hofmann, A. 47, 76; 53, 427; 74, 15; Greville Williams, Tr. E. 21 [2]; [3] 377; O. Fischer, B. 16, 720; Jacobsen a. Reimer, B. 16, 1084).

**Formation.**—1. By distilling quinine, cinchonine, or strychnine with potash (Gerhardt, A. 42, 310; 44, 279; O. de Coninck, C. R. 94, 87; Bl. [2] 35, 296). Quinoline free from homologues is got from cinchonine by treatment with potash and CuO (Wyschnegradsky, B. 13, 2318).—2. By passing allyl-aniline over heated  $PbO$  (Königs, B. 12, 453).—3. From hydrocarbostyryl (vol. i. p. 180) by treatment with  $PCl_5$  and reduction of the product with  $HI$  and HOAc (Baeyer, H. 12, 1320).—4. By distillation of acrolein-aniline (Königs, B. 13, 911).—5. By distilling anil-uvitonic acid with soda-lime (Böttlinger, B. 13, 2165).—6. By heating a mixture of nitro-benzene, aniline, glycerin, and  $H_2SO_4$  for three hours with inverted condenser (Skrapp, M. 1, 316; 2, 139, 535).—7. By heating its carboxylic acids with lime.—8. By adding a few drops of NaOHAq to a cold dilute solution of equimolecular quantities of o-amido-benzoic aldehyde and acetic aldehyde (Friedländer a. Gohring, B. 16, 1833).—9. By heating the hydrochloride of quinoline tetrahydride with water and  $Hg(OAc)_2$  at 150° (Tafel, B. 25, 1623).—10. By fusing methyl-acetanilide with  $ZnCl_2$  at 290° (Pictet, B. 23, 1903).

**Preparation.**—A mixture of aniline (38 pts.), glycerin (120 pts.), nitro-benzene (24 pts.) and  $\text{H}_2\text{SO}_4$  (100 pts.) is heated with inverted condenser. Potash is then added, and the base distilled over with steam and fractionally distilled. It may be further purified by means of the acid sulphate and freed from aniline by oxidation or by treatment in acid solution with  $\text{NaNO}_2$ . The yield is 60 p.c. (Skraup).

**Properties.**—Colourless liquid with peculiar odour, slowly becoming yellow. V. sl. sol. water, miscible with alcohol, ether, and  $\text{CS}_2$ . Quinoline is very hygroscopic, forming the hydrate  $(\text{C}_8\text{H}_7\text{N})_3\text{aq}$ , which becomes turbid on warming (Hoogewerff a. Van Dorp, *R. T. C.* 1, 1, 107). It is antiseptic, antipyretic, and antizymotic (Donath, *B.* 14, 178). Quinoline separated from solutions of its salts dissolves in excess of  $\text{NH}_3$  or ammonium carbonate, but not in  $\text{NaOH}$  or  $\text{Na}_2\text{CO}_3$ . Iodine in  $\text{KI}$  gives a brown pp., insol.  $\text{HClAq}$ . Phosphomolybdic acid a yellowish-white pp., sol.  $\text{NH}_4\text{Aq}$ . Picric acid a yellow amorphous pp.  $\text{HgCl}_2$  a white pp., sol.  $\text{HClAq}$ .  $\text{K}_2\text{HgI}_4$  a yellow amorphous pp., changed to yellow needles on adding  $\text{HCl}$ .  $\text{K}_2\text{Cr}_2\text{O}_7$  gives crystals, sol. excess. Potassium ferrocyanide an amorphous orange pp. (Donath, *B.* 14, 1763). On shaking with conc.  $\text{CuSO}_4\text{Aq}$  a green pp.  $(\text{CuSO}_4)_2(\text{CuO.H}_2\text{O})_4\text{aq}$  is got (Borsbach, *B.* 23, 924; cf. Lachovitch, *M.* 10, 884).  $\text{NaOBr}$  gives no reaction (Denigès, *C. R.* 107, 662). Quinoline forms very soluble crystalline compounds with  $\text{NaHSO}_4$  (Brunck a. Graebe, *B.* 15, 1785). It combines with iodoform (Rhoussopoulos, *B.* 16, 202).

**Reactions.**—1. On passing through a red-hot tube it yields (8)-diquinoyl (Zimmermann a. Müller, *B.* 17, 1965).—2. On boiling with sodium or sodium-amalgam it is converted into 'diquinoline', which forms a scarlet hydrochloride which dyes silk a transient orange (Greville Williams, *Pr.* 31, 536; *C. N.* 87, 85).—3. Reduced by tin and  $\text{HClAq}$  to quinoline tetrahydride (244) (Wysohnegradsky, *Bl.* [2] 31, 339).—4. Zinc-dust and  $\text{NH}_4\text{Aq}$  or alcohol and sodium-amalgam give the tetrahydrides of quinoline and of diquinoline (Königs, *B.* 14, 99).—5. Oxidised by bleaching-powder or other hypochlorites to oxyquinoline (carbostyryl) and chloro-oxy-quinoline (Erlenmeyer, *B.* 19, 489; Finhorn a. Lauch, *A.* 243, 342). Chlorine passed into its solution in  $\text{HOAc}$  forms tri-chloro-oxy-carbostyryl.—6. On heating with  $\text{SbCl}_5$  at  $170^\circ$ – $400^\circ$  and passing in chlorine, the products are  $\text{C}_8\text{Cl}_6$  and  $\text{C}_8\text{Cl}_8$  (Smith a. Davis, *C. J.* 41, 413).—7. Bromine (2 pts.) added to a mixture of quinoline (1 pt.) and water (3 pts.) forms the tetrabromide  $\text{C}_8\text{H}_7\text{NBr}_4$ , which crystallises from chloroform in very unstable red needles, and is converted, by heating with alcohol, into  $\text{C}_8\text{H}_7\text{NBr}_2\text{HBr}$  [ $86^\circ$ ] crystallising in red prisms, insol. chloroform, v. sol. alcohol and ether, decomposed at  $180^\circ$  into  $\text{HBr}$  and bromo-quinoline-hydrobromide (Grimaux, *Bl.* [2] 88, 125; *C. R.* 95, 85). Bromine added to an ethereal solution of quinoline forms the dibromide  $\text{C}_8\text{H}_7\text{NBr}_2$ , yielding  $\text{B'HCl}$  [ $100^\circ$ – $105^\circ$ ] and  $\text{B'HB'r}$  [ $88^\circ$  cor.], which form red crystals (Claus a. Collischonn, *B.* 19, 2765).—8.  $\text{KMnO}_4$  in alkaline solution forms pyridine dicarboxylic acid (Hoogewerff a. Van Dorp, *R. T. C.* 1, 1, 107; cf. Dewar, *Pr.* 26, 65).  $\text{KMnO}_4$  and conc.  $\text{H}_2\text{SO}_4$

also give quinolinic acid.  $\text{KMnO}_4$  and dilute  $\text{H}_2\text{SO}_4$  form quinoline (*B.* 3)-carboxylic acid, diquinoyl being an intermediate product (Georgievitch, *M.* 12, 312).—9.  $\text{H}_2\text{SO}_4$  at  $220^\circ$  forms the (*B.* 4)-sulphonic acid; at  $250^\circ$  the (*B.* 2)-sulphonic acid is produced (Georgievitch, *M.* 8, 578, 641).—10. Oxygen passed through platinised asbestos containing quinoline and quinoline hydrochloride at  $190^\circ$  forms (a)-diquinoyl. Oxygen acting on a mixture of aniline and quinoline hydrochloride forms (*Py.* 3; *B.* 2)-diquinoyl and *p*-amido-(*Py.* 3)-phenyl-quinoline, while quinoline and *o*-toluidine hydrochloride are converted by oxygen into amido-phenyl-methyl-quinoline (Weidel, *M.* 8, 120; *g.* 99).—11. *p*-Amido-phenyl-quinoline is also formed by heating quinoline hydrochloride with aniline.—12.  $\text{BzCl}$  at  $240^\circ$  gives (8)-diquinoyl.—13. Alloxan added to a solution of quinoline saturated with  $\text{SO}_2$  forms  $\text{B'C}_8\text{H}_7\text{N}_2\text{O}_5\text{SO}_2\text{H}_2$  crystallising in yellowish prisms (Pellizzari, *A.* 248, 150).—14.  $\text{SiCl}_4$  forms  $(\text{C}_8\text{H}_7\text{N})_2\text{SiCl}_4$  (Harden, *C. J.* 51, 40).  $\text{SiF}_4$  forms  $(\text{C}_8\text{H}_7\text{N})_2\text{SiF}_6$ , crystallising in needles (Corney a. Jackson, *Am.* 10, 176).—15. Nitroso-di-methyl-aniline and hydrogen cyanide form  $\text{B'}(C_8H_7NO)_2NMo_2H_2Cy$ , crystallising in golden plates (Lippmann a. Fleissner, *M.* 6, 543).—16. Glycerin dichlorohydrin forms  $(C_8H_7N)_2C_2H_4Cl_2$ , which is deliquescent and forms  $(B'C_8H_7Cl)_2PtCl_4$  and  $B'C_8H_7ClAuCl_4$ .—17. Ethylene chloride at  $100^\circ$  forms  $B'_2C_8H_7Cl_2$ , crystallising in needles, yielding  $B'_2C_8H_7PtCl_4$  (Rhoussopoulos, *B.* 16, 879).—18. Ethylene bromide (1 mol.) heated with quinoline (1 mol.) at  $80^\circ$  forms the bromo-ethylo-bromide  $B'TrC_8H_7Br$ , crystallising from alcohol in needles and yielding  $B'ClC_8H_7Br$  and  $(B'ClC_8H_7Br)_2PtCl_4$  (Berend, *B.* 14, 1349). Ethylene bromide (1 mol.) with quinoline (2 mols.) at  $40^\circ$  forms  $B'_2C_8H_7Br_2$  aq crystallising from alcohol in needles.—19. By heating quinoline (16 g.) with glycolic chlorohydrin (10 g.) and water (10 c.c.) for 3 days at  $100^\circ$  there is formed  $B'ClC_8H_7OH$ , crystallising from alcohol-ether in splendid prisms (Vurtz, *Pr.* 33, 452; *C. R.* 95, 263; 96, 1269). It is hygroscopic, v. sol. water and alcohol, insol. ether. On boiling with moist  $\text{Ag}_2\text{O}$  it forms a caustic liquid that soon turns crimson. It yields  $B'(C_8H_7OH)AuCl_4$ , crystallising in minute pointed hexagons, and also  $B'(C_8H_7OH)Cl_6HgCl_2$  and  $(B'(C_8H_7OH)Cl)_2PtCl_4$ .—20. Iodoform (1 mol.) heated with quinoline (2 mols.) for 8 days at  $100^\circ$  forms  $B'_2CH_3I_2$ , crystallising in long needles [ $132^\circ$ ] (Rhoussopoulos, *B.* 16, 202, 880, 2004). It is converted by  $\text{AgCl}$  into  $B'_2CH_3Cl_2$  [ $168^\circ$ ], which gives  $B'_2CH_3PtCl_4$ . Iodoform (1 mol.) added to quinoline (3 mols.) in ethereal solution forms  $B'_2CH_3I_2$ , crystallising in needles [ $55^\circ$ ], not affected by  $\text{AgCl}$ .—21. Chloro-acetic acid forms quinoline-betaine  $C_8H_7NO_2$  [ $171^\circ$ ], which separates from alcohol in thick crystals (containing aq) and forms  $(C_8H_7NO_2)_2H_2PtCl_4$  2aq (Gerichten, *B.* 15, 1254; Rhoussopoulos, *B.* 15, 2006).—22. Chloro-acetic ether forms  $C_8H_7NCl.CH_2.CO_2Et$  crystallising in needles, v. e. sol. water, converted by moist  $\text{Ag}_2\text{O}$  into quinoline. It yields the salt  $(C_8H_7NO_2)_2H_2PtCl_4$ .—23. Chloral in ether forms  $C_8H_7NC_2HClO$  aq [ $66^\circ$ ], crystallising from benzene (Rhoussopoulos, *B.* 16, 881). It is insol. water and decomposed by alcohol. It yields  $(C_8H_7NO.HClO)$  sol. 3PtCl. — 24. Resorcin at

100° forms  $(C_8H_7N)_2C_8H_5O_2$ , [102°], S. -25 in the cold (Hock, *B.* 16, 886). It crystallises from dilute alcohol in silvery plates, decomposed by  $HClAq.$ —25. *Phthalic anhydride* at 150° forms 'quino-phthalone'  $C_{12}H_7NO_2$ , [235°] (Traub, *B.* 16, 297).

**Salts.**— $B'HCl$ . [94°]. Deliquescent nodules, v. e. sol. alcohol, chloroform, and hot ether (O. de Coninck, *Bl.* [2] 37, 208).— $B'_2H_2PtCl_2 \cdot 2aq$  [225°] (Skraup); [218°] (Lellmann, *A.* 237, 323).— $B'_2H_2PtCl_2 \cdot aq.$  S. -07 at 11°.— $B'_2PtCl_2$ : insoluble powder.— $B'_2H_2PtCl_2$ .— $B'_2HAuCl_2$ . Canary-yellow needles.— $B'_2HCdCl_2 \cdot aq.$ — $B'_2CdCl_2$ : white pp.— $B'_2HgCl_2$ . Pearly plates (Bromeis, *A.* 52, 136).— $B'_2H_2HgCl_2 \cdot 2aq.$  [91°]. Monoclinic crystals.— $B'_2H_2PdCl_2$ . Crystals.— $B'_2H_2SnCl_2 \cdot 2aq$ : needles.— $B'_2HSnCl_2$ . [127°]. Thin needles.— $B'_2H_2SnCl_2$ . [above 240°].— $B'_2H_2UO_2Cl_2$ : yellow prisms.— $B'SbCl_2$ .— $B'_2HSbCl_2$ .— $B'_2H_2BiCl_2$ .— $B'_2H_2ZnCl_2$ .— $B'_2ZnCl_2$ .— $B'_2HgCl_2$ . [118°] (Ostermayer). Yellow pp., converted by ammonia into explosive  $B'NH_4I$  (Dittmar, *B.* 18, 1613).— $B'ICl$ . [160°]. Small white needles (Pictet a. Kraft, *Bl.* [3] 7, 73).— $B'Br \cdot HCl$ . [100°–105°]. Orange crystals (Claus, *B.* 19, 2766).— $B'IMnCl_2$ : rose-red needles (Borsebach, *B.* 23, 433).— $B'HFCl_2$ . [150°]. Formed by adding  $HCl$  to a solution containing quinoline and  $FeCl_3$  (B.). Small needles, decomposed by boiling water.— $B'_2CoCl_2$ : blue triclinic crystals.— $B'_2CuCl_2$ : nearly black crystals.— $B'_2Cu(OAc)_2$ . [above 240°]. Green crystalline powder.— $B'_2ZnI_2$ : white powder, sl. sol. cold water.— $B'_2ZnBr_2$ .— $B'_2CdBr_2$ .— $B'_2CdI_2$ .— $B'_2CdI_2$ .— $B'_2HgBr_2$ . [201°].— $B'_2HgI_2$ . [168°].— $B'Br_2$ . [92°–100°]. Red crystals (Lubavin, *J. R.* 18, 434).— $B'Br_2$ . Red needles.— $B'HBBr_2$ . [86°].— $B'Br \cdot HCl$ . [100°–105°].— $B'Br_2$ . [90°]. Formed by adding  $I$  to a solution of quinoline in  $CS_2$  (Claus a. Istel, *B.* 15, 824). Dark-green lustrous needles.— $B'HI_2$ . [87°]. Ppd. by adding  $I$  in  $KI$  to a solution of quinoline sulphate (Dafert, *M.* 4, 509). Green crystalline pp., sol. alcohol and benzene.— $B'HSO_3$ . [164°]. S. (alcohol) 2 at 18°; 11 at 78° (Krakau, *J. R.* 17, 361). Deliquescent crystals.— $B'_2H_2Cr_2O_7$ . [c. 167°]. Yellow needles (from hot water). S. -36 at 10°.— $B'HNO_3$ . Needles (from alcohol), v. sol. water, insol. ether.— $B'_2AgNO_3$ : needles.— $B'_2Hg(NO_3)_2$ : white crystalline precipitate.— $B'_2(HNO_3)_2Ce(NO_3)_3$ : orange-red plates (G. Williams, *C. N.* 58, 199).— $B'_2H_2SiF_6$ . Long needles (Corney a. Jackson, *Am.* 10, 176).— $B'_2H_2C_2O_4$ . Silky needles (from alcohol). Decomposes at 100° (Williams).— $B'_2HgCy_2$ : long needles (from water) (H. Schiff, *A.* 131, 112).—Tartrate  $B'_2AC_4H_8O_6$ . [125°] (Fries, *B.* 14, 2805).—Cyanurate  $B'_2H_2C_3N_3O_3$ . Crystals (Claus, *J. pr.* [2] 38, 226).— $B'HSyCy(Cr(SCy)_2NH_2)$ . Red lamellae, sl. sol. hot water (Christensen, *J. pr.* [2] 45, 365).—Picrate: [203°].—*o*-Oxybenzoate  $B'CH_2O_2$ . Crystalline powder.

**Alkyl-iodides.** According to Decker (*B.* 24, 690) the alkyl-iodides  $B'RI$  are converted by alkalis into the hydroxides  $B'ROH$  which are readily oxidised by the air to crystalline oxy- $\nu$ -alkyl-quinolines  $C_8H_7N \cdot \begin{smallmatrix} CH \\ | \\ NR.CO \end{smallmatrix}$  which melt about 100°. The cyanines may be considered as derived from one molecule of alkyl-quinoline and one molecule of oxy- $\nu$ -alkyl-quin-

oline. The alkyl-hydroxides are converted by warming with alcohols  $R'OH$  into compounds  $B'ROH$ .

**Methylo-chloride**  $B'MeCl \cdot aq.$  [126°]. On heating with  $ZnCl_2$  at 180° it is converted into a base  $C_{10}H_{13}N_2O$  [72°–75°] (above 860°), crystallising in large trimetric prisms, and yielding a hydrochloride [112°] and the double salts  $C_{10}H_{13}N_2OH \cdot AuCl_2$  and  $(C_{10}H_{13}N_2O)_2H_2PtCl_6$  [190°] nearly insol. water (Ostermayer, *B.* 18, 593).— $B'_2MePtCl_2$ . [230°]. Yellow plates.— $B'MeAuCl_2$ . [205°].— $B'MeClHCl$ . [112°]. Formed by adding  $ICl$  to the methylo-chloride in aqueous solution. Large yellow plates.

**Methylo-tribromide**  $B'MeBr_2$ . [123°]. Orange-red plates. Converted by picric acid solution into  $B'MeOC_6H_3(NO_2)_3$  [164°].

**Methylo-iodide**  $B'MeI$ . [73°] (La Coste, *B.* 15, 192; Pictet, *B.* 23, 1903). Large crystals. Converted by moist  $Ag_2O$  into a strongly alkaline solution of the hydroxide  $B'MeOH$ . Aqueous  $NaOH$  in the cold converts  $B'MeI$  into the oxide  $B'_2Me_2O$ , a white powder, reconverted by  $HI$  into  $B'MeI$  (possibly oxy- $\nu$ -methyl-quinoline) (La Coste; Claus, *B.* 15, 475; Bernthsen, *B.* 18, 29; Decker, *B.* 24, 690). Potash, even in cold aqueous solution, forms an oil probably containing methyl-quinoline (lepidine) (Skraup, *Sitz.* IV. [2] 81, 593). By the action of  $KOH$  on a mixture of  $B'MeI$  (2 pts.) and the methylo-iodide of (*ly.* 1)-methyl-quinoline (1 pt.) there is formed di-methyl-cyanine iodide  $C_{12}H_{15}N_2I$ , crystallising in oblong green tablets, [291°], sl. sol. water, forming a reddish-blue solution (Hoogewerf a. Van Dorp, *R. T. C.* 2, 317; 3, 337). The alcoholic solution is violet, with green fluorescence. Its solution in acids is yellow. The aqueous solution is decolourised by  $CO_2$ , the colour re-appearing on boiling. The corresponding  $C_{12}H_{15}N_2Cl \cdot 5aq$  [c. 300°] forms  $C_{12}H_{15}N_2Cl(HPtCl_6) \cdot aq$  as yellow crystals. Quinoline methylo-iodide is oxidised by alkaline  $K_2FeCy_4$  to oxy-methyl-quinoline or  $\nu$ -methyl-quinolone  $C_8H_7N \cdot \begin{smallmatrix} CH \\ | \\ NMe.CO \end{smallmatrix}$  [72°] (321° at 728 mm.) (Decker, *J. pr.* [2] 46, 31; cf. Bernthsen a. Hess, *B.* 18, 37, who took it for di-methyl-di-quinolyl; Ostermayer, *B.* 18, 591). This body is also got from carbostyryl and  $MeI$  (Friedländer a. Müller, *B.* 20, 2009). It deliquesces with water, forming an oil. Hydrochloride [112°].

**Ethylo-chloride**  $B'EtCl \cdot aq.$  [93°]. Large trimetric tables (Claus a. Tosse, *B.* 16, 1277).— $B'_2EtPtCl_2$ . [226°]. Yellow pp.

**Ethylo-bromide**  $B'EtBr \cdot aq.$  [80°]. Trimetric tables. By the action of (*py.* 1)-methyl-quinoline ethylo-bromide it is converted into di-ethyl-cyanine bromide  $C_{10}H_{13}N_2Br$  or  $C_{10}H_{13}N_2Br$ , crystallising in small needles, not melted at 290°, forming a blue solution in alcohol.

**Ethylo-iodide**  $B'EtI$ . [118°] (Spalteholz, *B.* 16, 1851; [160°] (Hoogewerf a. Dorp, *R. T. C.* 2, 321). Monoclinic crystals. At 280° it yields ( $\gamma$ )-ethyl-quinoline and di-ethyl-quinoline (Reher, *B.* 19, 2996). Moist  $Ag_2O$  forms strongly alkaline  $B'EtOH$ , which is sol. water and resinified by atmospheric oxidation. On heating  $B'EtI$  (2 pts.) with (*py.* 3)-methyl-quinoline ethylo-iodide (1 pt.) and alcoholic potash, there is formed di-ethyl-isocyanine iodide  $C_{12}H_{15}N_2I$

(Hoogewerff a. Van Dorp, *R. T. C.* 8, 344) or  $C_{10}H_8N_2I$  (Spalteholz, *B.* 16, 1851). This body forms lustrous green prisms (containing  $\frac{1}{2}$  aq or  $\frac{1}{2}$  EtOH or  $\frac{1}{2}$  EtOH  $1\frac{1}{2}$  aq) melting at  $152^\circ$ . It is insol. ether, sl. sol. water, and forms a crimson solution in alcohol. By the action of KOH on a mixture of B'EtI and (Py. 1)-methyl-quinoline ethyl-iodide there is formed di-ethyl-cyanine iodide  $C_{20}H_{18}N_2I$  [ $273^\circ$ ], crystallising in green prisms (Hoogewerff a. Van Dorp, *R. T. C.* 2, 317). Quinoline ethyl-iodide is oxidised by alkaline  $K_2FeCy$ , to  $C_8H_7\begin{smallmatrix} CH:CH \\ \diagup \quad \diagdown \\ NEt.CO \end{smallmatrix}$  ( $317^\circ$ )

(Decker, *J. pr.* [2] 47, 36), which body is also got from carbostyryl and EtI (Friedländer a. Weinberg, *B.* 18, 1530). Solidifies at  $-20^\circ$ .  $C_8H_7NEtHgCy_2$  [ $138^\circ$ ]. Needles (from water).  $C_8H_7NEtBrHgCy_2$  [ $155^\circ$ ]. Crystals (from alcohol) (Claus, A. 269, 271).

**Ethyl-nitrate** B'EtNO<sub>3</sub> [ $89^\circ$  uncor.]. Large trimetric crystals (Claus, *B.* 16, 1277).

**Propyl-chloride** B'PrCl aq. [ $95^\circ$ ] (hydrated); [ $135^\circ$ ] (anhydrous). Colourless crystals (Claus a. Collischonn, *B.* 19, 2504). Crystallises from chloroform in prisms (containing  $CHCl_3$ ) [ $79^\circ$ ]. V. e. sol. water.—B'PrClBr<sub>2</sub> [ $85^\circ$  uncor.]. Orange-red radiating crystalline mass.—B'PrCl<sub>2</sub> [ $62^\circ$ ]. Brown crystals.

**Propyl-bromide** B'PrBr 2aq. [ $66^\circ$  uncor.] (hydrated); [ $148^\circ$  uncor.] (anhydrous). Formed by heating quinoline with PrBr and a little (10 p.c.) alcohol at  $100^\circ$ . Tables, v. e. sol. water and alcohol. The anhydrous crystals (obtained from absolute alcohol) are very deliquescent. Crystals obtained from chloroform (containing  $CHCl_3$ ) melt at  $65^\circ$ – $129^\circ$ .—B'PrCl<sub>2</sub>Br. [ $60^\circ$ ]. Formed by passing dry Cl into a solution of B'PrBr in chloroform. Small sulphur-yellow plates. Unstable.—B'PrBr<sub>2</sub> [ $93^\circ$ ]. Formed by adding Br to the aqueous or alcoholic solution of B'PrBr. Triclinic garnet-red crystals. Yields (Py. 3)-bromo-quinoline on heating.—B'PrBrI<sub>2</sub> [ $60^\circ$  uncor.]. Formed by evaporating a mixture of I in ether and B'PrBr in alcohol. Lustrous brown needles.—B'PrBrI. [ $49^\circ$ ]. Slender, nearly black, needles with green reflex.

**Propyl-iodide** B'PrI. [ $145^\circ$ ]. Small yellow crystals. Not hygroscopic. Crystallises from chloroform with  $CHCl_3$ , partially melting at  $92^\circ$ .—B'PrCl<sub>2</sub>I. [ $87^\circ$ ]. Sulphur-yellow needles.—B'PrCl<sub>2</sub>I. [ $145^\circ$ ]. Converted by long boiling with water into B'PrCl.—B'PrBr<sub>2</sub>I. [ $77^\circ$ ]. Triclinic orange tables.—B'PrBr<sub>2</sub>I. [ $48^\circ$ – $58^\circ$ ]. Very unstable orange powder.—B'PrI<sub>2</sub> [ $62^\circ$ ]. Very stable bronzy brown prisms.—B'PrI<sub>2</sub> [ $50^\circ$ ]. Stable tables.

**Iso-amyl-chloride** B'C<sub>5</sub>H<sub>11</sub>Cl.—B'<sub>2</sub>(C<sub>5</sub>H<sub>11</sub>)<sub>2</sub>PtCl<sub>4</sub> [ $220^\circ$ ]. Yellow crystalline pp.

**Iso-amyl-bromide** B'C<sub>5</sub>H<sub>11</sub>Br aq. [ $87^\circ$ ] (hydrated); [ $140^\circ$ ] (anhydrous) (Claus a. Tosse, *B.* 16, 1277).

**Isoamyl-iodide** B'C<sub>5</sub>H<sub>11</sub>I. [ $185^\circ$ ]. Yellow monoclinic needles (Pörkin, *C. J.* 14, 246; Nadler a. Merz, *J. pr.* 100, 129; Greville Williams, *C. N.* 1861, 219; Hoogewerff a. Van Dorp, *R. T. C.* 2, 40; 3, 352; Arzruni, *R. T. C.* 4, 62). Does not form cyanine on treatment with potash unless it contains the isoamyl-iodide of (Py. 1)-methyl-quinoline, in which case di-isoamyl-cyanine iodide  $C_{20}H_{18}N_2I$

[c.  $100^\circ$ ] is produced. This body crystallises in lustrous green monoclinic crystals (containing  $1\frac{1}{2}$  aq);  $\alpha:b:c = 2.379:1:1.669$ ;  $\beta = 88^\circ 45'$ . It also forms brass-yellow crystals. It is very hygroscopic, nearly insol. ether, sl. sol.  $CHCl_3$ , acetone, and isoamyl alcohol. It is v. sol. alcohol, forming a deep-blue solution. Iodine converts it into  $C_{20}H_{18}N_2I$  [ $189^\circ$ ], which is sl. sol. alcohol, v. sol. acetone, forming blue solutions. The solution of di-isoamyl-cyanine iodide in HCl aq is colourless, and deposits on evaporation colourless scales of  $C_{20}H_{18}N_2I \cdot 2HCl$ , which at  $100^\circ$  gives off HCl, leaving bronzed  $C_{20}H_{18}N_2I \cdot HCl$ . Moist Ag<sub>2</sub>O forms uncrystallisable  $C_{20}H_{18}N_2(OH)$ . Alcohol and AgCl produce  $C_{20}H_{18}N_2Cl$  4aq, crystallising in long blue prisms, and yielding  $(C_{20}H_{18}N_2Cl)_2PtCl_6$ . Alcohol and AgNO<sub>3</sub> give  $C_{20}H_{18}N_2(NO_3)_2$  aq, which forms lustrous needles giving a blue aqueous solution and yielding colourless  $C_{20}H_{18}N_2(NO_3)_2 \cdot 2HCl$  and blue  $C_{20}H_{18}N_2(NO_3)_2HCl$ . Alcoholic ammonium sulphide converts the nitrate into reddish-yellow monoclinic crystals of  $C_{20}H_{18}N_2S_2O_8$ , which yields  $C_{20}H_{18}N_2S_2Cl_2 \cdot 2PtCl_6$  as an orange pp. (N. a. M.). H<sub>2</sub>SO<sub>4</sub> converts di-isoamyl-cyanine iodide into  $(C_{20}H_{18}N_2)_2SO_4$  2aq, crystallising from hot water in blue needles.

**Allyl-iodide** B'C<sub>3</sub>H<sub>5</sub>I. [ $177^\circ$ – $5^\circ$ ] (Pictet, *C. R.* 95, 300).

**Benzyl-chloride** B'C<sub>6</sub>H<sub>5</sub>Cl 3aq. [ $65^\circ$ ]. Triclinic tablets. It crystallises also as B'C<sub>6</sub>H<sub>5</sub>Cl 2aq [ $130^\circ$ ] in trimetric crystals (Claus, *B.* 13, 2045; 16, 1279; 18, 1305). V. sol. water and alcohol, insol. ether. KMnO<sub>4</sub> oxidises it to benzyl-o-amido-benzoic acid and its formyl derivative. By treatment with KOH or Ag<sub>2</sub>O it is converted into a strong base, v. sol. water. Excess of KOH ppts. an oil which turns red in air. The benzyl-hydroxide yields quinoline on distillation (Bernthsen a. Hess, *B.* 18, 35). Mercuric chloride yields a crystalline pp. [ $142^\circ$ ].—(B'C<sub>6</sub>H<sub>5</sub>)<sub>2</sub>PtCl<sub>4</sub> [ $246^\circ$ ]. Yellow pp.—B'C<sub>6</sub>H<sub>5</sub>ClBr<sub>2</sub> [ $92^\circ$ ]. Crystalline.—B'C<sub>6</sub>H<sub>5</sub>BrCl<sub>2</sub> [ $80^\circ$ ]. Yellow needles.—B'C<sub>6</sub>H<sub>5</sub>Br<sub>2</sub> [ $100^\circ$ ]. Orange prisms.—B'C<sub>6</sub>H<sub>5</sub>BrI<sub>2</sub> [ $110^\circ$ ]. Dark-violet needles.

**Phenacyl-bromide** B'Br.CH<sub>2</sub>.Bz. [ $115^\circ$ – $165^\circ$ ]. Needles, v. sol. water and alcohol, v. sl. sol. ether (Bamberger, *B.* 20, 3340).—B'HNO<sub>3</sub>.

**References.**—AMIDO-, BROMO-, BROMO-AMIDO-, BROMO-NITRO-, CHLORO-, CHLORO-NITRO-, IODO-, NITRO-, OXY-AMIDO-, and OXY-QUINOLINES.

#### Diquinoline v. DIQUINOLYL.

**Isoquinoline** C<sub>9</sub>H<sub>7</sub>N i.e.  $C_8H_6\begin{smallmatrix} CH:CH \\ \diagup \quad \diagdown \\ CH:N \end{smallmatrix}$  [ $23^\circ$ ]. ( $241^\circ$  i.V.). Occurs, as well as quinoline, in coal-tar (Hoogewerff a. Van Dorp, *R. T. C.* 4, 125, 285; 5, 305).

**Formation.**—1. By the action of HI at  $230^\circ$  or of zinc-dust in a current of H at a low red heat upon the di-chloro-derivative [ $123^\circ$ ] obtained by the action of POCl<sub>3</sub> on the imide of o-carboxy-phenyl-acetic acid  $C_6H_4\begin{smallmatrix} CH_2.CO \\ \diagup \quad \diagdown \\ CO.NH \end{smallmatrix}$

(Gabriel, *B.* 18, 3470; 19, 1656, 2361; Le Blanc, *B.* 21, 2299).—2. Together with di-isquinolyl, which yields B'<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub> [ $177^\circ$ ] by distilling benzylidene-ethyl-amine (Pictet a. Popovici, *B.* 25, 733).—3. By heating isocarbostyryl or its carboxylic acid with zinc-dust in a current of

hydrogen (Bamberger a. Kitschelt, *B.* 25, 1146; Zincke, *B.* 25, 1497).

**Properties.**—Hygroscopic tables. Yields phthalic and cinchonimeronic acids on oxidation by  $\text{KMnO}_4$ . Tin and  $\text{HClAq}$  give a tetra-hydrate. Forms crystalline compounds with  $\text{HgCl}_2$  and  $\text{AgNO}_3$ . Bromine in ether gives  $\text{C}_8\text{H}_7\text{NBr}_2$ , [82°], which forms very unstable  $\text{C}_8\text{H}_7\text{NBr}_2\text{HBr}$ , [c. 133°], converted at 200° into bromo-isquinoline [40°] (Edinger, *J. pr.* [2] 43, 191).

**Salts.**— $\text{B}'\text{H}_2\text{PtCl}_6 \cdot 2\text{aq}$ . [264°]. Reddish-yellow crystals.— $\text{B}'\text{HAuCl}_4$ . [225°]. Yellow needles.— $\text{B}'\text{HgCl}_2$ . [165°]. White needles.— $\text{B}'\text{H}_2\text{SO}_4$ . [206°].— $\text{B}'\text{H}_2\text{CrO}_4$ . needles.—Picrate  $\text{B}'\text{C}_6\text{H}_3\text{N}_3\text{O}_7$ . [223°]. Yellow needles.

**Methylo-iodide**  $\text{B}'\text{MeI}$  aq. [160°]. Flat yellowish needles. Treatment with  $\text{AgCl}$  and platinum chloride gives ( $\text{B}'\text{MeCl}$ ) $\text{PtCl}_4$  [240°] (Claus, *J. pr.* [2] 38, 492).  $\text{KOH}$  aq added to  $\text{B}'\text{MeI}$  forms an oily base which yields ( $\text{B}'\text{MeCl}$ ) $\text{PtCl}_4$  6aq. Oxidised by alkaline  $\text{K}_2\text{FeCy}_6$  to  $\nu$ -methyl-isquinoline  $\text{C}_8\text{H}_7$   $\begin{smallmatrix} \text{CH:CH} \\ \text{CO.NMe} \end{smallmatrix}$  [40°] (319°), sol. water, and yielding  $\text{B}'\text{H}_2\text{PtCl}_6 \cdot 2\text{aq}$  (Decker, *J. pr.* [2] 47, 37).

**Ethyl-iodide**  $\text{B}'\text{EtI}$ . [147°]. Yellowish-red tables. Yields ethyl-phthalimide on oxidation. Gives ( $\text{B}'\text{EtCl}$ ) $\text{PtCl}_4$ .

**Benzyl-chloride**  $\text{B}'\text{C}_6\text{H}_5\text{Cl}$ . V. sol. water and alcohol, sl. sol. ether (Goldschmidt, *M.* 9, 678). Yields benzyl-phthalimide [115°] on oxidation by  $\text{KMnO}_4$  in a solution kept neutral by  $\text{HCl}$ .

**Phenacylo-bromide**  $\text{B}'\text{BrCH}_2\text{Bz}$ . [205°]. Formed from isoquinoline and  $\omega$ -bromo-acetophenone dissolved in benzene (G.). Prisms (from alcohol), v. sol. water.  $\text{AgNO}_3$  forms  $\text{B}'\text{NO}_3(\text{CH}_2\text{Bz})$  crystallising in needles.

Diquinoline v. Diquinolyl.

#### QUINOLINE (B. 1.)-CARBOXYLIC ACID

$\text{CH:C}(\text{CO}_2\text{H})\text{C:CH:CH}$   
 $\text{CH:CH} \quad \text{C} \text{---} \text{N:CH'}$  Quinolins ana-carboxylic acid. Quinolins-m-carboxylic acid, [357°].

**Formation.**—1. Together with a smaller quantity of the (B. 3)-acid by heating *m*-amido-benzoic acid with glycerin,  $\text{H}_2\text{SO}_4$ , and *m*-nitro-benzoic acid (Schlosser a. Skraup, *M.* 2, 518; 7, 519).—2. By saponifying its nitrile, which is got by distilling sodium quinoline (B. 1)- or (B. 4)-sulphonate with  $\text{KCy}$  (Bedall a. Fischer, *B.* 14, 2574; 15, 683, 1980).—3. By heating quinoline (B. 1,4)-di-carboxylic acid (Skraup a. Brunner, *M.* 7, 153).

**Properties.**—White crystalline powder, sol. dilute acids and alkalis, insol. ether and benzene, v. sl. sol. water and alcohol.

**Salts.**— $\text{HA'HCl}$  1½aq: white needles.—( $\text{HA}'$ ) $\text{H}_2\text{PtCl}_6$ : yellow plates.— $\text{CaA}'_2 \cdot 2\text{aq}$ .— $\text{CaHA}' \cdot 6\text{aq}$ : needles.— $\text{HO.CuA}' \cdot 2\text{aq}$ : minute violet plates, insol. water.— $\text{AgA}'$ : crystalline pp.

**Nitrile**  $\text{C}_8\text{H}_7\text{N.CN}$ . [88°]. (above 360°). Formed as above and also from (B. 1)-amido-quinoline by diazotisation and treatment with  $\text{CuCy}_2$  (Freydl, *M.* 8, 581). Crystals, sl. sol. Aq.

**Tetrahydride**  $\text{C}_8\text{H}_9\text{NO}$ . [147°]. Formed by reducing the acid with tin and  $\text{HCl}$  (Fischer a. Körner, *B.* 17, 765). Yields a crystalline nitrosamine  $\text{C}_8\text{H}_9\text{N}_2\text{O}$ . [186°].

$\nu$ -Isomeride  $\text{C}_8\text{H}_7\text{NO}_2$ . [338°]. Perhaps identical with the preceding. Formed by warm-

ing quinoline with *m*-amido-benzoic acid, nitro-benzene, glycerin, and  $\text{H}_2\text{SO}_4$  (Lellmann a. Alt, *A.* 237, 818). Got also by saponifying its nitrile which is formed by fusing sodium quinoline  $\nu$ -ana-sulphonate with  $\text{KCy}$  in a current of hot air (Lellmann, *B.* 20, 1449; 21, 397). Snowy powder.— $\text{HA'HCl}$  aq.— $\text{H}_2\text{A}'\text{H}_2\text{PtCl}_6$ : needles.— $\text{ZnA}'_2$ — $\text{AgA}'$ .

**Tetrahydride**  $\text{C}_8\text{H}_9\text{NO}$ . [147°]. Got by reducing the acid or bromo-quinoline carboxylic acid with tin and  $\text{HClAq}$ .— $\text{HA'HCl}$  aq.

**Nitrile**  $\text{C}_8\text{H}_7\text{N.Cy}$ . [89°]. Needles (containing 1½aq), melting at 70°. Effloresces, and then contains ½aq and melts at 74.5°.— $\text{B}'\text{H}_2\text{PtCl}_6$ : needles.

#### Quinolins (B. 2)-carboxylic acid

$\text{CO}_2\text{H.C}=\text{CH.C:CH:CH}$   
 $\text{CH:CH.C} \text{---} \text{N:CH'}$  Quinolins-p-carboxylic acid. [291°]. Formed by heating *p*-amido-benzoic acid with glycerin, *p*-nitro-benzoic acid, and  $\text{H}_2\text{SO}_4$  (Schlosser a. Skraup, *M.* 2, 518). Formed also by heating its nitrile with  $\text{HClAq}$  at 140° (Fischer a. Wittmack, *B.* 17, 440). Thick prisms, sl. sol. hot water, s. sol. acids and alkalis.— $\text{HA'HCl}$ .—( $\text{HA}'$ ) $\text{H}_2\text{PtCl}_6$ .— $\text{CaA}'_2 \cdot 2\text{aq}$ .— $\text{AgA}'$ .

**Nitrile**  $\text{C}_8\text{H}_7\text{N}$ . [131°]. Formed by distilling potassium quinoline *p*-sulphonate (from sulphanilic acid) with  $\text{KCy}$ . Needles, forming a red solution in  $\text{HClAq}$ .

#### Quinolins (B. 3)-carboxylic acid

$\text{CH:CH.C:CH:CH}$   
 $\text{CO}_2\text{H.C}=\text{CH.C} \text{---} \text{N:CH'}$  Quinolins-m-carboxylic acid. [218°].

**Formation.**—1. By oxidation of ( $\beta$ )-di-quinolyl with  $\text{CrO}_3$  and  $\text{HOAc}$  (O. Fischer a. Loo, *B.* 17, 1901; 19, 2473).—2. By oxidation of (B. 3)-methyl-quinoline (Skraup a. Brunner, *M.* 7, 142).—3. By heating the stannochloride of *c*-amido-phthalic acid with *c*-nitro-phthalic acid, glycerin, and  $\text{H}_2\text{SO}_4$  (Tortelli, *G.* 16, 367).

**Properties.**—Needles (from water).

**Salts.**— $\text{Cu}(\text{OH})\text{A}'$  aq.— $\text{AgA}'$ .— $\text{HA'HCl}$  aq: triclinic prisms.— $\text{H}_2\text{A}'\text{H}_2\text{PtCl}_6$ : orange prisms.

#### Quinolins (B. 4)-carboxylic acid

$\text{CH:CH} \text{---} \text{C:CH:CH}$   
 $\text{CH:C}(\text{CO}_2\text{H})\text{C} \text{---} \text{N:CH'}$  Quinolins-o-carboxylic acid. [187°].

**Formation.**—1. By heating *o*-amido-benzoic acid with *o*-nitro-benzoic acid, glycerin, and  $\text{H}_2\text{SO}_4$  (Schlosser a. Skraup, *M.* 2, 518).—2. By heating its nitrile with conc.  $\text{HClAq}$  at 150° (Lellmann a. Reusch, *B.* 22, 1392).—3. Together with the (B. 1)-isomeride, by heating quinoline (B. 1,4)-di-carboxylic acid (Skraup a. Brunner, *M.* 7, 153).

**Properties.**—Needles, m. sol. cold water and alcohol.  $\text{FeSO}_4$  gives a purple colour in neutral solutions.— $\text{HA'HCl}$ : yellowish prisms.— $\text{H}_2\text{A}'\text{HCl}$ : golden prisms.— $\text{H}_2\text{A}'\text{H}_2\text{PtCl}_6$ : orange needles.— $\text{CaHA}'_2$ : needles.— $\text{AgA}'$ : pp.

**Methylo-iodide**  $\text{HA'MeI}$ . Slender yellow needles (La Coste, *B.* 15, 196). Moist  $\text{Ag}_2\text{O}$  forms a solution of the hydroxide which reproduces  $\text{HA}'$  on evaporation.

**Nitrile**  $\text{C}_8\text{H}_7\text{N}$ . [84°]. Needles. Yields  $\text{B}'\text{H}_2\text{PtCl}_6$ , crystallising in orange needles.

#### Quinolins (Py. 1)-carboxylic acid

$\text{O}_2\text{H}_2 \text{---} \text{C}(\text{CO}_2\text{H})\text{CH}$   
 $\text{N} \text{---} \text{CH}$  Cinchoninic acid. [254°].

**Formation.**—1. By oxidation of cinchonine,

**cinchonidine**, **cinchotenine**, **cinchotenidine**, **cinchonitine**, and **cincholepidine** (Weidel, *A.* 178, 84; *M.* 8, 79; Skraup, *A.* 201, 303; *M.* 2, 601; Forst a. Böhrringer, *B.* 14, 436; Schniderschnitsch, *M.* 10, 55).—2. By oxidation of (*Py.* 1)-methyl-quinoline (lepidine) (Hoogewerff a. Van Dorp, *R. T. C.* 2, 11).

**Preparation**.—By boiling cinchonine with nitric acid of S.G. 1.3 (Königs, *B.* 12, 97; Claus, *B.* 18, 362).

**Properties**.—Slender needles (containing aq) (Skraup) or triclinic crystals (containing 2aq)  $a:b:c = .746:1:817$ ;  $\alpha = 81^\circ 37'$ ;  $\beta = 120^\circ 2'$ ;  $\gamma = 86^\circ 37'$  (Muthmann a. Nef, *B.* 20, 637). By slow evaporation of an aqueous solution it is obtained in monoclinic forms (containing 2aq),  $a:b:c = .276:1:533$ ;  $\beta = 98^\circ 3'$  (Ditscheiner, *A.* 173, 84; Claus, *B.* 20, 1604). V. sl. sol. water and alcohol, insol. ether. Yields quinoline on distillation with lime, and oxy-quinoline carboxylic acid on fusion with potash. On heating with conc.  $H_2SO_4$  it yields quinoline *p*-sulphonic acid (Georgievitch, *M.* 8, 644). Sulphuric acid and  $P_2O_5$  at  $175^\circ$  gives an ( $\alpha$ )-sulphonic acid  $C_8H_7N(SO_3H)(CO_2H)$ , which forms very bitter triclinic crystals (containing aq), nearly insol. cold water, giving the salts  $(NH_4)'A'$  2aq,  $CaA'$  2aq,  $BaA'$  3aq,  $PbA'$  4aq, and  $CuA'$  2aq.  $H_2SO_4$  and  $P_2O_5$  at  $260^\circ$  give a ( $\beta$ )-sulphonic acid  $C_8H_7NSO_3$ , crystallising in bitter needles (containing 2aq), m. sol. cold water, forming the salts  $(NH_4)'HA'$  2aq,  $BaA'$  4aq, and  $PbA'$  4aq (Weidel, *M.* 1, 845; 2, 565; Georgievitch, *M.* 8, 644).— $KMnO_4$  forms pyridine tricarboxylic acid.

**Salts**.— $HA'HCl$ .— $(HA')_2H_2PtCl_6$ : triclinic prisms.— $HA'HClO_4$  2aq (Dittmar, *B.* 18, 1618).— $HA'HNO_3$ .— $(HA')_2H_2SO_4$ : long prisms.— $KA'$  1aq.— $CaA'$  1aq: prisms (Weidel).— $CaA'_2$  (Skraup).— $CuA'_2$ : dark-violet plates, sl. sol. hot water.— $AgA'$ : crystalline pp.

**Dibromide**  $C_{10}H_7NO_2Br_2$ . [188°]. Long red needles, decomposed by boiling water (Claus, *B.* 18, 1307).

**Di-iodide**  $C_{10}H_7NO_2I_2$ . [c. 242°]. Steel-blue tables, nearly insol. cold water.

**Ethyl ether EtA'**. [13°]. Trimetric crystals, v. sl. sol. water, v. sol. ether, sl. sol. alcohol (Van der Kolf a. Van Leent, *R. T. C.* 8, 217).— $EtA'HgCl_2$ . [153°]. Small needles.— $(EtA')_2H_2PtCl_6$ . [204°]. Orange-yellow needles.

**Amide**  $C_{10}H_7N_2O$ . [181°]. Needles, v. e. sol. hot water.— $B'H_2PtCl_6$ . [250°–255°].

**Benzoylo-bromide**  $C_{10}H_7NO_2C_6H_5Br$ . [130°]. Silky needles, v. sol. water and alcohol, insol. ether. By heating the aqueous solution or by treatment with alkalis, it is converted, by loss of  $HBr$ , into the anhydride  $C_{10}H_7N_2C_6H_5$ , which crystallises in dimetric tables (containing 8aq) [84°] and has a bitter taste. This anhydride is converted by alkalis into  $C_8H_7N(C_6H_5)CO_2H$  [218°] (Claus a. Muehall, *B.* 18, 363, 1310).

**Tetrahydride**  $C_{10}H_9NO_2$ . Formed from cinchonine acid, tin, and  $HClAq$  (Weidel, *M.* 2, 29; 3, 61). Yields a nitrosamine [137°].— $B'HCl1\frac{1}{2}aq$ : monoclinic crystals;  $a:b:c = .932:1:1.942$ ;  $\beta = 90^\circ 41'$ . Heated with  $H_2SO_4$  it gives disulpho-cinchonic acid and methyl-quinoline (cincholepidine).— $B'_2H_2PtCl_6$ .

**Acetyl derivative of the Tetrahydride**  $C_{10}H_{11}AcNO_2$ . [164°]. Trimetric crystals;  $a:b:c = .848:1:569$ . Sl. sol. cold water and alcohol.— $CaA'_2$  2aq: minute needles.

**Quinoline (*Py.* 2)-carboxylic acid**

**Formation**.—1. By heating acridinic acid at  $125^\circ$  (Graebe a. Caro, *B.* 13, 100).—2. By oxidation of (*Py.* 2)-ethyl- (or methyl-) quinoline (Riedel, *B.* 16, 1609; Doebner a. Miller, *B.* 18, 1643).

**Properties**.—Slender needles, sol. alcohol, sl. sol. cold water. Dissolves in acids and alkalis. Oxidised by  $KMnO_4$  to pyridine tricarboxylic acid.

**Salts**.— $HA'HCl$ : needles, v. sol. water.—**Picrate**: [ $216^\circ$ ].— $CuA'_2$ .— $AgA'$ : small prisms.— $(HA')_2H_2PtCl_6$ : orange needles.

**Quinoline (*Py.* 3)-carboxylic acid**

Formed from (*Py.* 3)-methyl-quinoline by oxidation with chromic acid mixture (Doebner a. Miller, *B.* 16, 2472). Got also by oxidation of ( $\alpha$ )-diquinolyl (Weidel a. Strache, *M.* 7, 300). Needles (containing 2aq), v. sol. hot water, acids, and alkalis.— $CuA'_2$  2aq.— $CaA'_2$ .— $AgA'$ : amorphous precipitate.— $AgHA'_2HNO_3$  aq: silky needles.— $HA'HCl$  aq.— $(HA')_2H_2PtCl_6$  2aq.— $(HA')_2H_2CrO_4$ : sparingly soluble red crystals.

**Quinoline (*B.* 1,4)-di-carboxylic acid**

$CH:C(CO_2H)C.CH:C.H$   
 $CH:C(CO_2H)C.N=CH$  [270°]. Formed by heating amido-terephthalic acid with glycerin,  $H_2SO_4$ , and o-nitro-phenol (Skraup a. Brunner, *M.* 7, 147). Long needles (containing 2aq), v. sl. sol. cold water. Salts.— $HA'HCl$  1aq.— $(HA')_2H_2PtCl_6$ .— $Cu_2A'_2(HO)_2$  2aq: bluish pp.

**Quinoline (*Py.* 2,3)-dicarboxylic acid**

$C_8H_7 \begin{array}{l} \text{CH:C.CO}_2H \\ \text{N=C.CO}_2H \end{array}$  **Acridinic acid**. Formed by oxidation of acridine with  $KMnO_4$  (Graebe a. Caro, *B.* 13, 99). Long needles (containing 2aq), sl. sol. cold water, v. sol. alcohol. Does not combine with acids. Decomposed by heat into  $CO_2$  and a mono-carboxylic acid [275°].

**Quinoline (*Py.* 1,3)-dicarboxylic acid**

$C_8H_7 \begin{array}{l} \text{C(CO}_2H)C.H \\ \text{N=C.CO}_2H \end{array}$  [246°]. Formed from (*Py.* 3)-styryl-cinchonic acid by oxidation with alkaline  $KMnO_4$  (Doebner a. Peters, *B.* 22, 3009). Needles, sl. sol. cold water and alcohol.— $CuA''$  aq.— $Ag_2A''$ : white pp.

**Quinoline ( $\alpha$ )-dicarboxylic acid**

$C_8H_7N(CO_2H)_2$ . [270°]. Formed by saponifying its nitrile. Slender needles (containing aq), sl. sol. alcohol and ether.

**Nitrile**  $C_8H_7NCy_2$ . [222°]. Formed by heating potassium quinoline ( $\alpha$ )-disulphonate with  $KCy$  (La Coste a. Valeur, *B.* 20, 99). Needles (from alcohol), insol. Aq, v. sol. alkalis.

**Quinoline (*B.* 2, *Py.* 3)-dicarboxylic acid**

Formed by oxidation of benzylidene-quinoline (*B.* 2)-carboxylic acid (Von Miller, *B.* 23, 2261).

**References**.—Bromo-, Nitro-, and Oxy-QUINOLINE CARBOXYLIC ACIDS.

**QUINOLINE (*Py.* 3)-CARBOXYLIC ALDEHYDE**  $C_8H_7N.CHO$ . [71°]. Formed by oxida-

tion of (Py. 8)-quinolyl-acrylic acid with  $\text{KMnO}_4$  (Miller a. Spady, *B.* 18, 8404; 19, 180). Mono-clinic plates (from ligroin), sl. sol. water. Reduces ammoniacal  $\text{AgNO}_3$ . Yields a phenyl-hydrazide  $\text{C}_{18}\text{H}_{15}\text{N}_2$  [198°] crystallising in yellow plates.

#### QUINOLINE HYDRIDES.

**Polymeride of quinoline dihydride**  $\text{C}_{18}\text{H}_{13}\text{N}_2$  [182°]. Formed by reducing quinoline with zinc-dust and  $\text{HOAc}$ , zinc-dust and  $\text{NH}_3$ , zinc and  $\text{HClAq}$ , or alcohol and sodium-amalgam (Königs, *B.* 12, 101, 252; 14, 99; Wyschnegradsky, *B.* 12, 1481; Lellmann, *B.* 22, 1337). Amorphous powder. Its solution in conc.  $\text{HClAq}$  is ppd. by water and by  $\text{NaOAc}$ . Yields a nitrosamine.

**Quinoline dihydride (?)**. (220°–226°). Found in small quantity among the products of the action of  $\text{KOH}$  on quinoline (O. de Coninck, *C. R.* 94, 87).— $\text{B}'_2\text{H}_2\text{PtCl}_4$ .

**Quinoline tetrahydride**  $\text{C}_8\text{H}_7\text{N}$  i.e.

$\text{C}_8\text{H}_7\text{N} \begin{smallmatrix} \text{CH}_2\text{CH}_2 \\ \text{NHCH}_2 \end{smallmatrix}$  [c. 10°]. (240° uncor.).

**Formation**.—1. By reduction of quinoline with zinc or tin and  $\text{HClAq}$  (Wyschnegradsky, *B.* [2] 34, 339; *B.* 12, 1481; 13, 2400), with zinc-dust and  $\text{NH}_3\text{Aq}$ , with alcohol and sodium-amalgam (Königs, *B.* 14, 99; 16, 727), or with sodium (Weidel a. Glaser, *M. F.* 7, 328).—2. From carbostyryl, alcohol, and  $\text{Na}$  (Knorr a. Klotz, *B.* 19, 3302).

**Properties**.—Needles, sol. water, volatile with steam. Secondary base. ICl forms in presence of  $\text{HCl}$  an amorphous pp.  $\text{C}_8\text{H}_7\text{N}$  (Dittmar, *B.* 18, 1619).

**Reactions**.—1. The vapour passed through a red-hot tube yields indole and quinoline.—2. Chromic acid mixture yields quinoline.—3. Nitro-benzene yields quinoline. *p*-Chloro-nitro-benzene at 200° does the same (Lellmann a. Reusch, *B.* 22, 1389).—4.  $\text{HI}$  and  $\text{P}$  reduce it to  $\text{C}_8\text{H}_{11}$ , an oil (147° at 720 mm.) (Bamberger a. Lengfeld, *B.* 23, 1158).—5. Br forms oily  $\text{C}_8\text{H}_7\text{BrN}$  and  $\text{C}_8\text{H}_7\text{Br}_2\text{N}$ .—6. Benzene sulphonic chloride and  $\text{NaOH}$  form  $\text{C}_8\text{H}_7\text{N} \cdot \text{SO}_3\text{C}_6\text{H}_5$  [67°], crystallising in plates, sl. sol. alcohol, insol. water (Schotten a. Schlömann, *B.* 24, 3695).—7. Methyl chloroformate gives  $\text{C}_8\text{H}_7\text{N} \cdot \text{CO}_2\text{Me}$  [c. 35°], which may be oxidised by  $\text{KMnO}_4$  in the cold to an acid [156°] and at 100° to a compound [175°] crystallising in red needles.—8. Diazobenzene chloride and aqueous  $\text{NaOAc}$  form  $\text{C}_8\text{H}_7\text{N} \cdot \text{N}_2\text{C}_6\text{H}_5$ , which is split up by dilute  $\text{H}_2\text{SO}_4$  into phenol and quinoline tetrahydride.—9. Potassium cyanate acting on the hydrochloride forms  $\text{C}_8\text{H}_7\text{N} \cdot \text{CO} \cdot \text{NH}_2$  [150–5°], crystallising in needles, sl. sol. cold water. It is converted by conc.  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  at 0° into  $\text{C}_8\text{H}_7(\text{NO}_2) \cdot \text{N} \cdot \text{CO} \cdot \text{NH}_2$  [191°], sl. sol. alcohol, and  $\text{C}_8\text{H}_7(\text{NO}_2)_2\text{N}$  [161°], v. sol. alcohol, which forms a nitrosamine [127°] (Thomas, *R. T. C.* 10, 148).—10. Benzoic aldehyde and  $\text{ZnCl}_2$  yield  $\text{CHPh}(\text{C}_8\text{H}_7\text{N})_2$  [153°], while *p*-nitro-benzoic aldehyde forms a corresponding body [177°] (Einhorn, *B.* 19, 1243).

**Salts**.— $\text{B}'\text{HCl}$ . [181°].— $\text{B}'_2\text{H}_2\text{PtCl}_4$ .— $\text{B}'\text{H}_2\text{SO}_4$ . [137°]. Prisms (from alcohol) or tables (from water).

**Acetyl derivative**  $\text{C}_8\text{H}_7\text{N} \cdot \text{Ac}$ . (295°). Yields  $\text{CO}_2\text{H} \cdot \text{CO} \cdot \text{NH} \cdot \text{C}_8\text{H}_7 \cdot \text{CO}_2\text{H}$  [12] on oxidation by  $\text{KMnO}_4$ .

Vol. IV.

**Benzoyl derivative**  $\text{C}_8\text{H}_7\text{N} \cdot \text{Bz}$ . [75°]. Tables (from alcohol). Oxidised by  $\text{KMnO}_4$  to benzoyl-isatic acid (Schotten, *B.* 24, 772).

**Nitrosamine**  $\text{C}_8\text{H}_7\text{N}(\text{NO})$ . Oil. Converted by alcoholic  $\text{HCl}$  into the isomeric (*B.* 2)-nitroso-quinoline tetrahydride [134°], which separates from benzene in steel-blue crystals, converted by  $\text{NaNO}_2$  and  $\text{HOAc}$  into  $\text{C}_8\text{H}_7\text{N}_2\text{O}_2$  [98°] (Ziegler, *B.* 21, 864). Phenyl-hydrazine forms  $\text{C}_8\text{H}_7\text{N}_2\text{O} \cdot \text{PhN} \cdot \text{H}_2$  [120°]. Zinc-dust and  $\text{HOAc}$  reduce the nitrosamine to the hydrazine  $\text{C}_8\text{H}_7\text{N}(\text{NH}_2)$  [56°] (c. 255°), which crystallises from ligroin, and forms  $\text{B}'_2\text{H}_2\text{SO}_4$  2aq, crystallising in yellow plates. The hydrazine is oxidised in ethereal solution by ppd.  $\text{HgO}$  to the tetrazone  $\text{C}_8\text{H}_7\text{N}_4$ , which forms colourless needles [160°], sol. ether, sl. sol. alcohol.

**Methylo-chloride v. Hydrochloride of  $\nu$ -METHYL-QUINOLINE TETRAHYDRIDE.**

**Ethyl-iodide**  $\text{B}'\text{EtI}$ . Changed by alkalis into  $\nu$ -ethyl-quinoline tetrahydride, which is a liquid (254°–258°) yielding  $(\text{C}_8\text{H}_7\text{NEt})_2\text{H} \cdot \text{CdCl}_2$  [105°], and  $(\text{C}_8\text{H}_7\text{NEt})_2\text{H} \cdot \text{PtCl}_2$  [c. 160°] (Wyschnegradsky, *B.* 13, 2400; Claus a. Stegelitz, *B.* 17, 1329).

**Quinoline tetrahydride**  $\text{C}_8\text{H}_7\text{N}$ . (213°). Formed by distilling cinchonine (1 pt.) with  $\text{KOH}$  (3 pts.) (O. de Coninck, *C. R.* 94, 87; *A. Ch.* [5] 21, 478). Got also by distilling brucine with potash (De Coninck, *C. R.* 90, 1077). Slightly hygroscopic oil, v. sol. acids. Reduces  $\text{FeCl}_3$ . May be oxidised to quinoline.— $\text{B}'\text{HCl}$ : deliquescent needles, v. sol. water.— $\text{B}'_2\text{H}_2\text{PtCl}_4$ .— $\text{B}'_2\text{H}_2\text{PtCl}_4$ : pale orange plates.

**Quinoline hexahydride**  $\text{C}_8\text{H}_9\text{N}$ . (227°) at 720 mm. A product of the action of  $\text{HI}$  and  $\text{P}$  at 230° on the hydrochloride of quinoline tetrahydride (Bamberger a. Lengfeld, *B.* 23, 1155). Liquid, turning brown in air, m. sol. hot water.  $\text{FeCl}_3$  gives a brown colour on warming. Diazo benzene sulphonic acid gives a light-red colouring matter. Phosphomolybdic acid gives a white pp. Potassio-mercuric iodide gives no pp.  $\text{NaNO}_2$  in acid solution gives an oily pp. of the nitrosamine.— $\text{B}'\text{HCl}$ . [170°]. Silky needles.  $\text{B}'\text{HBr}$ . Long silky needles.

**Quinoline decahydride**  $\text{C}_8\text{H}_{11}\text{N}$  i.e.

$\text{CH}_2\text{CH}_2\text{CH}(\text{CH}_2\text{CH}_2\text{CH}_2)\text{CH}_2$  [43–5°]. (204° at 714 mm.).

Formed by heating the hydrochloride of quinoline tetrahydride (3 pts.) with  $\text{HI}$  (16 pts. of S.G. 1.9) for 7 hours at 230° (Bamberger a. Lengfeld, *B.* 23, 1145). Needles or prisms (from ligroin). Smells like couine. Fumes with  $\text{HCl}$ . Sublimes, in needles, in the cold. M. sol. water, v. sol. alcohol and ether, sl. sol. alkalis. Gives no colour with  $\text{FeCl}_3$  or diazo salts. Reduces ammoniacal  $\text{AgNO}_3$  in alcoholic solution. Phosphomolybdic acid gives a white flocculent pp. changing to needles. Potassio-mercuric iodide added to the acid solution gives scarlet crystals changing to black prisms on warming.

**Reactions**.—1. Phenyl-cyanate forms, in ethereal solution,  $\text{C}_8\text{H}_{11}\text{N} \cdot \text{CO} \cdot \text{NHPh}$ , crystallising in needles [148°].—2. Phenyl thiocarbimide in ether forms  $\text{C}_8\text{H}_{11}\text{N} \cdot \text{CS} \cdot \text{NHPh}$ , crystallising from chloroform in tables [134–5°].—3. An ethereal solution of  $\text{CS}_2$  gives  $\text{C}_8\text{H}_{11}\text{N} \cdot \text{CS} \cdot \text{SNH} \cdot \text{C}_6\text{H}_5$ , crystallising in needles [120°], not decomposed by boiling alcohol, but converted by iodine into

CC

( $C_9H_7N$ )HI and  $S_2(GS.NC.H_{12})_2$ , which crystallises in colourless needles [81°], sol. alcohol.

**Salts.**—B'HCl. [276°]. Small tables.—B'HI. [253°]. Silky needles.—B'HAuCl<sub>4</sub>. [96°]. Golden needles.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>. [207-5°].

**Acetyl derivative**  $C_9H_7N.Ac$ . Oil.

**Benzoyl derivative**  $C_9H_7N.Bz$ . [44°].

**ISOQUINOLINE TETRAHYDRIDE**  $C_9H_{11}N$ . (232°). Formed by the action of tin and HCl upon isoquinoline (Hoogewerff a. Van Dorp, *R. T. C.* 5, 305). Liquid, smelling like isoquinoline, sl. sol. water. Absorbs  $CO_2$  from the air, forming a crystalline carbonate. The aqueous solution reduces  $AgNO_3$ . Yields an oily nitrosamine.—B'HCl. [96°]. Tables, sol. alcohol. Not hygroscopic.—B'<sub>2</sub>H<sub>2</sub>SO<sub>4</sub>: sol. alcohol.—B'<sub>2</sub>H<sub>2</sub>PtCl<sub>6</sub>. [232°]. Reddish-yellow tables, decomposed by hot water.

**QUINOLINE-HYDROQUINONE** v. Di-oxo-quinoline.

**QUINOLINE-IODOFORM** v. QUINOLINE, Reaction 20.

**QUINOLINE-QUINONE**  $C_9H_7NO_2$  i.e.

$CH.CO.C.CH:CH$   
 $CH.CO.C.N=CH$ . Formed by the action of cold chromic acid mixture on (B. 4,1)-oxy-amido-quinoline (Fischer a. Renouf, *B.* 17, 1644). Flat needles with green reflex (from alcohol), decomposing at 110°-120°. Its salts are decomposed by water. Reduced by sulphurous acid to di-oxo-quinoline. Aniline in alcoholic solution forms, on boiling, the dianilide  $C_{12}H_{10}N_2O_2$ , crystallising from dilute alcohol in small coppered plates with green reflex [o. 190°], forming a violet solution in HClAq.

**Mono-oxim**  $CH.C(NOH).C.CH:CH$   
 $CH.CO — C.N=CH$ .

Formed by the action of  $NaNO_2$  and HClAq on (B. 4)-oxy-quinoline (Von Kostanecki, *B.* 24, 152). Needles (from alcohol). Gradually blackens below 220°, decomposing completely at 245°.

**Di-oxim**  $CH.C(NOH).C.CH:CH$   
 $CH.C(NOH).C.N=CH$ . Formed by adding hydroxylamine hydrochloride to an aqueous solution of the mono-oxim (Von Kostanecki a. Reicher, *B.* 24, 156). Minute crystals.  $Ac_2O$  yields a crystalline di-acetyl derivative decomposing below 160° with evolution of gas. Dyes cotton mordanted with iron salts greenish-black.

**Quinoline-o-quinone**  $C_9H_7NO_2$ . Formed by oxidising (B. 2)-oxy-(B. 1 or 3)-amido-quinoline with  $FeCl_3$  in acid solution (Mathéus, *B.* 21, 1887). Unstable.—B'HCl: long reddish-yellow needles. Decomposed by  $Na_2CO_3$ , forming a brown solution. The sulphate forms yellow plates.

**Mono-oxim**  $C_9H_7N(OH)(NOH)$ . Formed from p-oxo-quinoline,  $NaNO_2$ , and HCl (M.). Golden needles (from  $HOAc$ ), sl. sol. ether.

**Di-oxim**  $C_9H_7N(OH)(NOH)$ . Needles, decomposing at 190° (Von Kostanecki a. Reicher, *B.* 24, 158). Converted by conc. KOHAq into the anhydride  $C_9H_5N_2O$ , which forms colourless needles, readily volatile with steam.

**QUINOLINE (B. 1)-SULPHONIC ACID**

$CH:C(SO_3H).C.CH:CH$   
 $CH:CH — C.N=CH$ . A product of the sulphonation of quinoline (O. Fischer, *B.* 15, 6:8, 1979; 20, 731; La Coste a. Valeur, *B.* 20,

97). Formed also from amido-benzene *m*-sulphonic acid, nitrobenzene, glycerin, and  $H_2SO_4$  at 160° (Lellmann a. Lange, *B.* 20, 1446). Mono clinic needles (containing aq). Yields oxy-quinoline [224°] by potash-fusion.— $CaA'$ , 5aq: needles v. e. sol. water. According to Lellmann, there exists an isomeric quinoline (B. 1)-sulphonic acid, also got by sulphonation of quinoline, with  $H_2SO_4$  (containing 50 p.c.  $SO_3$  extra) at 260° (Lellmann, *B.* 20, 2172). This  $\psi$ -acid is converted by conc.  $H_2SO_4$  at 250°-300° into the (B. 2)-acid (Lellmann, *B.* 22, 1391). The  $\psi$ -acid forms anhydrous crystals.

**Tetrahydride**  $C_9H_7N.SO_3H$  aq. [315°] Formed by reducing the above acid (B. 4)-bromo-quinoline (B. 1)-sulphonic acid and also (B. 4)-oxy-quinoline (B. 1)-sulphonic acid with tin and HClAq (Lellmann a. Lange, *B.* 20, 3087; Claus, *J. pr.* [2] 42, 344). Trimetric crystals (from dilute solutions) or monoclinic crystals (from conc. solutions).  $FeCl_3$  gives a brown colour passing through purple to grass-green on warming.

**Quinoline (B. 2)-sulphonic acid**  
 $SO_3H.C=CH.C.CH:CH$   
 $CH:CH.C.N=CH$ . Formed by heating a mixture of amido-benzene-*p*-sulphonic acid, glycerin, nitrobenzene, and  $H_2SO_4$  (Happ, *B.* 17, 191). Formed also to the extent of 70 p.c.) by heating quinoline with conc.  $H_2SO_4$  at 240°-300° and by heating the (B. 1)- or ( $\beta$  4)- acid with conc.  $H_2SO_4$  at 240°-300° (Georgievitch, *M.* 8, 578, 639). Monoclinic needles (containing  $1\frac{1}{2}$  aq), sl. sol. alcohol and cold water. Not melted at 260°. Potash-fusion yields (B. 2)-oxy-quinoline [193°]. Bromine-water gives a yellow pp. of di-bromo-quinoline [126°] and at 100° Br (3 mols.) forms tri-bromo-quinoline [170°] (Claus a. Küttner, *B.* 19, 2884). Heating with KCy gives  $C_9H_7N.Cy$  [131°] which on saponification yields the carb-oxylie acid [288°].

**Salts.**— $KA'$  (dried at 120°). Tables.— $BaA'$ , (dried at 120°).— $AgA'$ : slender needles.— $Ag_2HA'$ : needles.— $(HA')_2K_2I_6$  6aq: lustrous green crystals.

**Ethyl ether**  $EtA'$  2aq. Crystals, v. sol. water (Claus a. Happ, *B.* 18, 366).— $EtA'KI_3$ : unstable brown needles, v. sol. water (Claus a. Stegelitz, *B.* 19, 921).— $EtA'KBr_3$ .— $EtA'HgCl_4$ .

**Benzyl ether**  $C_6H_5A'$  2aq. Monoclinic crystals.— $C_6H_5A'KI_3$ : needles with blue reflex.

**Quinoline (B. 3)-sulphonic acid**  
 $CH:CH.C.CH:CH$   
 $SO_3H.C=CH.C.N=CH$ . [above 300°]. Formed

by heating quinoline with  $H_2SO_4$  (containing 15 p.c.  $SO_3$  extra) at 130° (Claus, *J. pr.* [2] 37, 260). Small needles, v. e. sol. water, v. sol. alcohol. Potash-fusion yields oxy-quinoline [165°-200°]. Bromine forms di-bromo-quinoline [255°] and tri-bromo-quinoline [199°].— $NaA'$  3aq.  $KA'$  2aq.— $CaA'$ , 4aq.— $BaA'$ , 4aq.— $PbA'$ .— $CuA'$  2aq: dark-green crystalline powder.

**Ethyl ether**  $EtA'$ . [275°]. Needles (from alcohol).

**Chloride**  $C_9H_7N.SO_3Cl$ . Viscid mass.

**Amide**  $C_9H_7N.SO_3NH_2$ . [119°]. Crystalline.

**Quinoline (B. 4)-sulphonic acid**

$CH:CH — C.CH:CH$   
 $CH:C(SO_3H).C.N=CH$ . **Quinoline o-sulphonic acid**. Formed, together with a smaller quantity of the *p*- acid, by heating quinoline with fuming

$\text{H}_2\text{SO}_4$  at  $170^\circ$  (O. Fischer a. Bedall, *B.* 15, 683, 1979; 20, 731; Riemerschmied, *B.* 16, 721; La Coste a. Valeur, *B.* 20, 95; Claus, *B.* 19, 925, 2882; *J. pr.* [2] 37, 260). Formed also by heating quinoline with conc.  $\text{H}_2\text{SO}_4$  at  $220^\circ$  (Georgievitch, *M.* 8, 641). Monoclinic prisms, v. sl. sol. water. Oxidised by  $\text{KMnO}_4$  to pyridine dicarboxylic (quinolinic) acid (Fischer, *B.* 17, 755) and a small quantity of (1,2,3)-sulpho-amido-benzoic acid (Zürcher, *B.* 21, 180). Changed by conc.  $\text{H}_2\text{SO}_4$  at  $250^\circ$  to the (B. 2)-isomeride (Georgievitch, *M.* 8, 578). Bromine-water forms a yellow insoluble pp. and, at  $100^\circ$ , tri-bromo-quinoline [198°].

**Salts.**— $\text{NaA}'$  5aq (Spies, *J. pr.* [2] 37, 265).— $\text{KA}'$  2aq.— $\text{CaA}'$  9aq. Monoclinic crystals.— $\text{PbA}'$ — $\text{CuA}'$  2aq: small green needles.

*Ethyl ether* EtA'. [66°]. Needles (from chloroform). Decomposed by boiling water.

*Chloride*  $\text{C}_8\text{H}_7\text{NSO}_2\text{Cl}$  [124°]. Needles.

*Amide*  $\text{C}_8\text{H}_7\text{N}_2\text{SO}_2\text{NH}_2$  [184°]. Needles (from water) (Hoogewerff a. van Dorp, *R. T. C.* 8, 184). Converted by Br and  $\text{KOH}$  into  $\text{C}_8\text{H}_7\text{NSO}_2\text{NBrK}$  2aq, crystallising in yellow needles, m. sol. water, and converted by  $\text{HOAc}$  into  $\text{C}_8\text{H}_7\text{NSO}_2\text{NBrH}$ , crystallising from acetone in needles, yielding  $(\text{C}_8\text{H}_7\text{NSO}_2\text{NBr})_2\text{Ba}$  2aq.

**Quinoline ( $\alpha$ )-disulphonic acid**  
 $\text{C}_8\text{H}_7(\text{SO}_3\text{H})_2\text{N}$ . Formed, together with the ( $\beta$ )-isomeride, by heating quinoline (B. 4)-sulphonic acid with fuming  $\text{H}_2\text{SO}_4$  at  $250^\circ$  (La Coste a. Valeur, *B.* 19, 995; 20, 98). Yellow needles (containing 3aq), v. sol. water, insol. alcohol.— $\text{KA}''$  3½aq: satiny plates, v. e. sol. water.— $\text{BaA}''$  3aq. S. 4.08 at  $15^\circ$ .

**Quinoline ( $\beta$ )-disulphonic acid**  
 $\text{C}_8\text{H}_7(\text{SO}_3\text{H})_2\text{N}$ . Formed as above (La Coste a. Valeur, *B.* 19, 998; 20, 3199). Needles (containing 1½aq), v. sol. water, insol. alcohol.— $\text{KA}''$  aq: crusts, sl. sol. cold water.— $\text{BaA}''$  2aq: white powder, sl. sol. cold water (difference from ( $\alpha$ )-isomeride).

**References.**—Bromo- and Oxy-quinoline SULPHONIC ACIDS.

#### ISOQUINOLINE SULPHONIC ACID

$\text{C}_8\text{H}_7(\text{SO}_3\text{H})_2\text{N}$ . Formed by heating isoquinoline (1 pt.) with fuming  $\text{H}_2\text{SO}_4$  (2 pts.) at  $100^\circ$  (Hoogewerff a. van Dorp, *R. T. C.* 5, 305).— $\text{BaA}'$  9aq. Needles, v. sol. water.

**QUINOLINIC ACID** v. PYRIDINE DICARBOXYLIC ACID. The name is also given by Dewar (*Pr.* 30, 164) to an acid  $\text{C}_8\text{H}_5\text{NO}_4$  [143°] formed in small quantity in the oxidation of quinoline (derived from cinchonine) by boiling aqueous  $\text{KMnO}_4$ .

( $\alpha$ )-DIQUINOLYL  $\text{C}_{16}\text{H}_{12}\text{N}_2$ , i.e.  
 $\text{C}_8\text{H}_7\text{—CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{—C}_8\text{H}_7$ . *Diquinoline*.  
 $\text{C}_8\text{H}_7\text{—N=O—O=N—C}_8\text{H}_7$ . [176°]. (above  $400^\circ$ ). V.D. 8.73 (calc. 8.86).

**Formation.**—1. By heating quinoline with sodium at  $192^\circ$  (Weidel, *M.* 2, 491; 7, 327).—2. In small quantity (8 p.c.) by passing dry oxygen into a mixture of quinoline and quinoline hydrochloride in presence of platinum-black (Weidel, *M.* 8, 120).

**Properties.**—Monoclinic plates,  $a:b:c = 1.87:1.1:32$ ;  $\beta = 109^\circ 58'$ . Insol. water, sol. alcohol, ether, and benzene. Oxidised by  $\text{KMnO}_4$  and  $\text{HOAc}$  to cyclothraustic ( $\text{C}_7\text{H}_7\text{N}_2\text{O}_2$ ), quinoline (*Py.* 8)-carboxylic, oxyisochinomeronic (oxy-pyridine dicarboxylic), and  $\alpha$ -amido-benzoic

acids (Weidel a. Strache, *M.* 7, 280, 306; 8, 197). Alkaline  $\text{KMnO}_4$  forms isochinomeronic,  $\alpha$ -amido-benzoic, and pyridanthric ( $\text{C}_8\text{H}_7\text{N}_2\text{O}_2$ ) acid.  $\text{MeOH}$  and  $\text{H}_2\text{SO}_4$  form  $\text{B}''\text{MeSO}_3\text{H}$  (Ostermayer, *B.* 18, 333, 597).

**Salts.**— $\text{B}''\text{H}_2\text{Cl}$  4aq: white needles.— $\text{B}''\text{H}_2\text{PtCl}$  aq.— $\text{B}''\text{HAuCl}$  2aq.— $\text{B}''\text{H}_2\text{SO}_4$  aq.

*Methylo-chloride*  $\text{B}''\text{Me}_2\text{Cl}$  6aq: needles.— $\text{B}''\text{Me}_2\text{Cl}_2$  2Cl. [238°]. Lemon-yellow pp.

*Methylo-iodide*  $\text{B}''\text{MeI}$ . [283°].

*Ethyl-iodide*  $\text{B}''\text{EtI}$ . Yellow needles (from water), sl. sol. water (Roser, *B.* 17, 2769).

**Sulphonic acid**  $\text{C}_{16}\text{H}_{11}\text{N}_2(\text{SO}_3\text{H})_2$ . Formed by heating diquinolyl with  $\text{H}_2\text{SO}_4$  (containing 5 p.c.  $\text{SO}_3$  extra) (Weidel a. Gläser, *M.* 7, 308). Minute needles, almost insol. hot water, sol. conc.  $\text{HCl}$  aq and  $\text{H}_2\text{SO}_4$ . Converted by potash-fusion into oxy-diquinolyl [208°].— $\text{KA}'$  2aq: needles, v. e. sol. water.— $\text{CaA}'$  2aq.

( $\alpha$ )-Disulphonic acid  $\text{C}_{16}\text{H}_{10}(\text{SO}_3\text{H})_2\text{N}_2$ . Formed by heating diquinolyl (10 pts.) with  $\text{H}_2\text{SO}_4$  (11 pts.) and  $\text{SO}_3$  (34 pts.) at  $170^\circ$  (Weidel, *M.* 2, 503). Minute needles, sl. sol. water. Yields, by potash-fusion, di-oxy-diquinolyl [239°].— $\text{KA}''$  6aq: needles.— $\text{CaA}''$  6aq: bluish-green crystals, nearly insol. water.

( $\beta$ )-Disulphonic acid  $\text{C}_{16}\text{H}_{10}(\text{SO}_3\text{H})_2\text{N}_2$ . Formed, together with the mono-sulphonic acid, by heating ( $\alpha$ )-diquinolyl (100 pts.) with  $\text{H}_2\text{SO}_4$  (332 pts.) and  $\text{SO}_3$  (18 pts.) for 20 hours at  $190^\circ$  (Weidel a. Gläser, *M.* 7, 322). Small needles, converted by potash-fusion into di-oxy-diquinolyl [above  $305^\circ$ ].— $\text{KA}''$  (dried at  $120^\circ$ ): crystalline powder.— $\text{CaA}''$  (dried at  $120^\circ$ ).

( $\beta$ )-Diquinolyl

$\text{CH:CH:C:CH:C:CH:CH} > \text{C}_8\text{H}_7$ . [192°].  
 $\text{CH:N—C:CH:C:CH:N}$

**Formation.**—1. By heating quinoline with  $\text{BzCl}$  at  $253^\circ$  (Japp a. Graham, *C. J.* 39, 174).—

2. In very small quantity by distilling cinchoninic acid with lime (Weidel, *M.* 2, 501).—3. By passing quinoline through a red-hot tube (Zimmermann a. Müller, *B.* 17, 1965).—4. By distilling quinoline (B. 4)-sulphonic acid; the yield being 10 p.c. (O. Fischer a. Loo, *B.* 17, 1899; 19, 2472).

**Properties.**—Iridescent plates (by sublimation) or colourless prisms (from ether), sol. hot benzene, alcohol, and ether, insol. water. Weak base, the salts being decomposed by water. Oxidised by  $\text{CrO}_3$  and  $\text{HOAc}$  to quinoline (B. 3)-carboxylic acid.  $\text{CrO}_3$  and  $\text{H}_2\text{SO}_4$  give pyridyl-quinoline carboxylic acid  $\text{C}_8\text{H}_7\text{N.C}_8\text{H}_7\text{N.CO}_2\text{H}$  [273°]. Bromine forms  $\text{C}_{16}\text{H}_{12}\text{N}_2\text{Br}$  [192°].

**Salts.**— $\text{B}''\text{H}_2\text{SO}_4$ : sparingly soluble concentric needles.— $\text{B}''\text{H}_2\text{PtCl}$ : granular pp.

*Ethyl-iodide*  $\text{B}''\text{EtI}$ . Very unstable red crystals, decomposed by hot water.

**Disulphonic acid**  $\text{C}_{16}\text{H}_{10}(\text{SO}_3\text{H})_2\text{N}_2$ . Formed by heating the base (1 pt.) with conc.  $\text{H}_2\text{SO}_4$  (10 pts.) at  $180^\circ$ . V. e. sol. water.— $\text{KA}''$  3aq: prisms.

( $\gamma$ )-Diquinolyl

$\text{CH:N—C:CH:CH:CH:CH:C:N—CH}$   
 $\text{CH:CH:C:CH:C—C=CH:C:CH:CH}$  *Di-p-quinolyl*. [178°].

**Formation.**—1. By boiling a mixture of benzidine, nitrobenzene, glycerin, and  $\text{H}_2\text{SO}_4$  (Roser, *B.* 17, 1817, 2767; O. W. Fischer, *M.* 5, 418; Colson, *C. R.* 108, 677). A better yield is got by using *o*- or *p*-nitrophenol instead of nitro-

benzene (Ostermayer a. Henrichsen, *B.* 17, 2444). When crude benzidine is used there is also formed a base  $C_{12}H_{16}N_4O_2$ , which yields  $B'2SnCl_2$  [135°] and  $B''H_2PtCl_6$  2aq (Colson, *C. R.* 107, 1008; 108, 677).—2. By heating azobenzene with glycerin and  $H_2SO_4$  (Claus a. Stegelitz, *B.* 17, 2380).

**Properties.**—Monoclinic crystals, insol. water, sl. sol. ether, v. sol. hot alcohol and benzene.  $MeOH$  and  $H_2SO_4$  at 180° form  $B''(MeHSO_4)_2$  2aq, crystallising in needles. Bromine in alcohol forms unstable  $C_{12}H_{12}N_4Br_2$  and  $C_{12}H_{14}N_4Br_2$ , converted by  $HClAq$  at 190° into  $C_{12}H_{11}BrN_2$  [150°–155°].

**Salts.**— $B''H_2Cl_2$  4aq: white needles.— $B''HAuCl_2$  2aq: slender needles.— $B''H_2SnCl_2$ : colourless needles.— $B''H_2PtCl_6$  (dried at 105°).— $B''H_2Cl_2$  2Cl: chessy pp. (Dittmar, *B.* 18, 1618).— $B''H_2SO_4$  3aq.— $B''2H_2SO_4$ .— $B''2H_2Cr_2O_7$ .— $B''C_6H_5(NO_2)_2OH$ : minute yellow prisms.

**Methylo-iodides**  $B''MeI$ . Crystals.— $B''MeI_2$ . [c. 300°]. Yellow needles, sol. water.

**Ethylo-iodide**  $B''2EtI$ . [270°]. Needles.

**Disulphonic acid**  $C_{12}H_{10}(SO_3H)_2N_2$ . White powder, insol. water and alcohol.— $Na_2A''$  5aq: small needles. The same, or an isomeric, disulphonic acid is got by heating benzidine disulphonic acid with *o*-nitro-phenol, glycerin, and  $H_2SO_4$ . It crystallises in plates or needles, and yields  $K_2A''$  aq.

(8)-Diquinolyl

[148°]. Formed by heating *o*-*p*-di-amido-di-phenylhydrochloride with nitrobenzene, glycerin, and  $H_2SO_4$  (O. W. Fischer, *M.* 6, 546). Leaflets, insol. water, sol. hot alcohol and benzene. Bromine in presence of water forms orange needles of  $C_{12}H_{12}N_4Br_2$ .— $B''H_2Cl_2$ : needles, v. o. sol. water.— $B''H_2PtCl_6$  aq: reddish-yellow crystalline pp.—Picrate. [168°]. Yellow needles.

**Methylo-iodide**  $B''MeI$ . [126°]. Needles.

**Disulphonic acid**  $C_{12}H_{10}(SO_3H)_2N_2$ . Four-sided tables, not melted at 300°. Sl. sol. hot water.— $BaA''$  3aq: needles, m. sol. hot water.

(Py. 3, B. 1 or 3)-Diquinolyl  $C_{12}H_{12}N_4$ . [159°]. Formed (7 pts.), together with the isomeride [115°], by heating a mixture of *m*-amido-(Py. 3)-phenyl-quinoline (20 pts.), glycerin (70 pts.), *o*-nitro-phenol (15 pts.), and  $H_2SO_4$  (60 pts.) (Miller a. Kinkelin, *B.* 18, 1910). Small monoclinic tables, sl. sol. ether, cold alcohol, and chloroform.— $B''H_2Cl_2$  2aq: plates.— $B''H_2PtCl_6$ .— $B''H_2SO_4$ : easily soluble needles.— $B''C_6H_5N_2O$ , [240°]. Crystalline powder.

**Methylo-iodide**  $B''MeI$ . [263°]. Needles.

(Py. 8, B. 3 or 1)-Diquinolyl  $C_{12}H_{12}N_4$ . [115°]. Formed as above (M. a. K.). Light-yellow triclinic crystals, v. sol. alcohol, ether, and benzene, sl. sol. ligroin.— $B''H_2Cl_2$  3aq: tables, v. e. sol. water.— $B''H_2PtCl_6$ : crystalline.

(Py. 3, B. 1)-Diquinolyl

Formed from *p*-amido-(Py. 3)-phenyl-quinoline, glycerin, nitro-benzene, and  $H_2SO_4$  (Weidel, *M.* 8, 140). It is also a product of the action of oxygen on a mixture of quinoline hydrochloride, aniline, and platinised asbestos at 180°. Monoclinic tables (from alcohol).— $B''H_2PtCl_6$ : crystalline powder.— $B''HCl$ : yellow.— $B''H_2Cl_2$ .

**Methylo-iodide**  $B''MeI$  aq. [232°]. Small needles (from water), sl. sol. boiling water.

**Sulphonic acid**  $C_{12}H_{11}(SO_3H)N_2$ . Insoluble powder. Potash-fusion yields an oxy-diquinolyl [187°].

(B., Py. 1)-Diquinolyl  $C_{12}H_{12}N_4$ . [122°]. Got by heating (α)-amido-(Py. 1)-phenyl-quinoline [150°] with glycerin, nitro-benzene, and  $H_2SO_4$  (Koenigs a. Nef, *B.* 20, 632). Large crystals (from benzene). May be distilled. V. e. sol. alcohol, v. sl. sol. ether. Strong base.— $B''H_2PtCl_6$ : granules, sol. conc.  $HClAq$ .

(B., Py. 1)-Diquinolyl  $C_{12}H_{12}N_4$ . [117°]. Got by heating (β)-amido-(Py. 1)-phenyl-quinoline [198°] with glycerin, nitro-benzene, and  $H_2SO_4$  (Koenigs a. Nef, *B.* 20, 634). Tables (from benzene), v. e. sol. alcohol. May be distilled. Strong base.— $B''H_2PtCl_6$ : yellow needles.—Picrate. [248°]. Bulky flakes.

(Py. 2,3)-Diquinolyl

Formed by the action of (Py. 3)-quinolyl-acetic aldehyde on α-amido-benzoic aldehyde in alcoholic solution (Carlier a. Einhorn, *B.* 23, 2895). Plates (from alcohol).—Aurochloride: [248°].—Platinochloride: [278°].— $B''H_2Cl_2$  4aq.

**Methylo-iodide**  $B''MeI$ .

**Diquinolyl tetrahydride**  $C_{12}H_{16}N_2$ . [118°]. Formed by heating (Py. 3)-chloro-quinoline with quinoline tetrahydride (Friedländer a. Weinberg, *B.* 18, 1533). Crystals, sl. sol. ligroin, insol. water. May be distilled.  $HClAq$  forms a deep-yellow solution.

**Reference.**—OXYDIQUINOLYL.

(Py. 3)-QUINOLYL-ACETIC ACID

$C_6H_5-CH:CH$   
 $N=C.C_6H_5.CO_2H$  [275°]. Formed from the aldehyde by potash-fusion or by oxidation (Carlier a. Einhorn, *B.* 23, 2896). Formed also by oxidation of α-oxy-quinolyl-propionic acid with  $KMnO_4$ . Needles (from alcohol).—Hydrochloride: [243°]; needles.—Silver salt: white scales, yielding quinaldine on distilling with lime.

(Py. 3)-QUINOLYL-ACETIC ALDEHYDE

$C_{12}H_{16}NO$  i.e.  $C_6H_5.N.CH_2.CHO$ . [104°]. Formed by careful oxidation of α-oxy-quinolyl-propionic acid (Einhorn, *B.* 18, 3467; 19, 908). Crystals (from alcohol). Yields a phenyl-hydrazide [199°].— $B''H_2PtCl_6$  2aq.— $B''C_6H_5N_2O$ , [212°].

QUINOLYL-ACETONE v. ACETONYL-QUINOLINE.

(Py. 3)-QUINOLYL-ACETYLENE

$C_6H_5.N.C:CH$ . Formed by distilling a solution of di-bromo-quinolyl-propionic acid with  $Na_2CO_3$  (Carlier a. Einhorn, *B.* 23, 2896). Volatile oil. Br forms  $C_6H_5N.CBr:CHBr$ .

(Py. 3)-QUINOLYL-ACRYLIC ACID

Formed by the action of boiling potassium carbonate solution upon 'quinolyl-acrylo-trichloride'  $C_6H_5.N.CH:CH.CCl_3$  aq [146°], which is got by heating (Py. 3)-methyl-quinoline with chloral at 110° (Miller a. Spady, *B.* 18, 3402, 3465; 19, 130; Einhorn, *B.* 19, 908). Plates. Oxidised by  $KMnO_4$  to aldehydo-quinoline.  $HBr$  forms β-bromo-quinolyl-propionic acid.— $BaA''$ : needles, sl. sol. cold water.— $HA'HCl$ : needles.

**QUINOLYL-ACRYLO-TRICHLORIDE***supra*.**TRI-(B. 3)-QUINOLYL-CARBINOL**

( $C_9H_7N$ ),  $C.OH$ . [108°]. Formed by oxidising tri-quinolyl-methane with  $H_2CrO_4$  and  $HOAc$  (Noelting a. Schwarz, B. 24, 1608). Needles, v. sol. alcohol, sl. sol. ligroin.

**(B. 3, Py. 3)-QUINOLYLENE DIACRYLIC ACID**

$CH:CH.C:CH:CH$   
 $CO_2H.CH:CH.C=CH.C.N=C.CH:CH.CO_2H$ .  
 [over 300°]. Formed by boiling tri-chloro-propenyl-quinolyl-acrylic acid with  $K_2CO_3$  (Eckhardt, B. 22, 284). Sol. acids and alkalis. Insol. water, sl. sol. hot alcohol.

**DI-(B. 2)-QUINOLYL-ETHANE**  $C_{20}H_{15}N_2$ , i.e.  $C_9H_7N.CH_2.CH_2.C_9H_7N$ . [124°]. Formed by heating di-*p*-amido-di-phenyl-ethane with nitrophenol, glycerin, and  $H_2SO_4$  (Corney, B. 23, 1115). Hexagonal plates, insol. water, sl. sol. ether.— $B''H_2Cl_4$  aq.: needles, v. sol. water.— $B''H_2Cl_2$ .— $B''H_2PtCl_6$ .— $B''H_2AuCl_4$ .—Sulphate: prisms, m. sol. cold water.

**(Py. 3)-QUINOLYL-ETHYLENE**  $C_{11}H_9N$ , i.e.  $C_9H_7N$ 

$CH:CH$   
 $C_9H_7N < N = C.CH:CH_2$ . Formed by boiling  $\beta$ -bromo-quinolyl-propionic acid with conc.  $K_2CO_3$  (Einhorn, A. 246, 172). Oil.— $B''H_2PtCl_4$  aq. [187°].— $B''H_2AuCl_4$ . [159°].

(B. 3, Py. 3)-Di-quinolyl-ethylene  $C_{20}H_{15}N_2$ , i.e.  $C_9H_7N$   
 $CH:CH$   
 $C_9H_7N < N = C.CH:CH.C=CH.C.N=C.CH:CH$ .  
 Formed by heating *m*-amido-(Py. 3)-styryl-quinoline with *o*-nitro-phenol, glycerin, and  $H_2SO_4$  (Wartmann, B. 23, 3650). Oil, v. sol. alcohol, sl. sol. ether.

*Methylo-iodide*  $B'MeI 1\frac{1}{2}$  aq. [226°]. Golden needles, v. sol. hot water and alcohol. Yields  $C_{20}H_{15}N_2.Br.MeI$ . [210°].

**QUINOLYL-DI-ETHYL-PHENOL**  $C_{19}H_{19}NO$ , i.e.  $C_9H_7N.C_2H_5Et_2.OH$ . This is probably the constitution of apocinchene (Comstock a. Königs, B. 20, 2674; v. vol. ii. p. 174).

**(B. 4)-QUINOLYL-HYDRAZINE**  $C_9H_7N_2$ , i.e.  $CH:CH.C:CH:CH$ 

$CH:N-C \cdots C.N.H_2$  [64°]. Formed from (B. 4)-amido-quinoline by diazotisation and treatment with  $SnCl_2$  and  $HCl$  (Dutton, C. J. 59, 757; Böttger, B. 24, 3277). Needle (from ether) or prisms (from ligroin).— $B''H_2Cl_4$ : prisms. Converted by potassium cyanate and  $HCl$  into  $C_9H_7N.NH.NH.CO.NH_2$  [235°], and by pyruvic acid into  $C_9H_7N.N_2H.CMe.CO_2H$  crystallising in orange needles, converted by boiling  $HCl$  aq into quinindole ( $\alpha$ )-carboxylic acid  $C_9H_7N_2O_2$  [286°].

(B. 1)-Quinolyl-hydrazine [151°]. Formed in like manner from *ana*-amido-quinoline (Dutton, C. J. 61, 785). Yellow needles (from water). Yields  $B'HCl$  [248°] and is converted by cyanic acid into  $C_9H_7N.NH.NH.CO.NH_2$  [235°], by benzoic aldehyde into  $C_9H_7N.NH.N:CHPh$  [194°], by acetone into  $C_9H_7N.NH.N:CMe_2$  [140°] and by pyruvic acid into the acid  $C_9H_7N.NH.N:CMe.CO_2H$  [185°], whence boiling  $HCl$  aq forms the corresponding quinindole carboxylic acid, which decomposes at about 300°.

**DIQUINOLYLNE** IS DIQUINOLYL.

**DI-(B. 2)-QUINOLYL KETONE** ( $C_9H_7N$ ),  $CO$ . [174°]. Formed from di-*p*-amido-benzophenone, glycerin,  $H_2SO_4$ , and picric acid (Noelting a. Schwarz, B. 24, 1608). Needles, v. sol. alcohol,

sl. sol. hot water.— $B''H_2Cl_4$  [over 200°]. Needles, v. e. sol. water and alcohol.

**(Py. 3)-QUINOLYL-MERCAPTAN**

$C_9H_7N < CH:CH$   
 $C_9H_7N < N = C.SH$  [174°]. Formed by heating (Py. 3)-oxy-quinoline with  $P_2S_5$  at 145° (Roos, B. 21, 620). Yellow plates, sl. sol. hot water, v. sol. hot alcohol. Yellow dye. Combines with acids and bases. Does not react with hydroxylamine or phenyl-hydrazine.

*Ethyl derivative*  $C_9H_7N.SET$ . Formed from quinolyl-mercaptan,  $NaOEt$ , and  $EtI$ . Oil, decomposed by distillation.— $B''HI$ . [154°].— $B''H_2PtCl_4$  aq. [c. 190°]. Octahedra.

**TRI-(B. 2)-QUINOLYL-METHANE**

$CH(C_9H_7N)_3$ . [202°]. Formed from *p*-rosauilone, glycerin,  $H_2SO_4$ , and picric acid at 150° (Noelting a. Schwarz, B. 24, 1606). Needles (containing  $EtOH$ ), melting at 98°. Melts at 202° when anhydrous.— $B''H_2I_2Cl_4$ : plates, sol. water.— $B''C_6H_5N_3O_2$ : yellow needles.— $B''H_2PtCl_4$ : yellow crystals.— $B''H_2MeI$ . [266°].

**(B. 2)-QUINOLYL-METHENYL-AMIDOXIM**

$C(NOH)(NH_2).C=CH.C.CH:CH$   
 $CH:CH.C.N=C.H$  [105°]. Formed from  $C_9H_7N.Cy$ , hydroxylamine hydrochloride,  $Na_2CO_3$ , and dilute alcohol (Biedermann, B. 22, 2761). Yellowish needles, m. sol. hot water. Fehling's solution gives a greyish-green pp.  $FeCl_3$  gives a deep-red colour.  $AgNO_3$  gives a white pp. yielding a mirror.

*Reactions*.—1. *Phthalic anhydride* on warming forms  $C_9H_7N.C < \begin{smallmatrix} N.O \\ N \end{smallmatrix} > C.C_6H_4.CO_2H$  [203°].

2.  $Ac_2O$  yields  $C_9H_7N.C < \begin{smallmatrix} N.O \\ N \end{smallmatrix} > CMe$  [175°], crystallising in needles.—3. The hydrochloride is converted by potassium cyanate into  $C_9H_7N.C(NOH).NH.CO.NH_2$  [165°].—4. *Chloroformic ether* forms  $C_9H_7N.C(NH).NO.CO.Et$  [97°], which is converted by  $NaOH$  aq into  $C_9H_7N.C < \begin{smallmatrix} N.O \\ NH \end{smallmatrix} > O$  [155°].

Salts.— $B''HCl$ : needles.— $B''H_2PtCl_4$ .

*Acetyl derivative*  $C_9H_7N.C(ONAc).NH_2$ . [115°]. Formed by means of  $AcCl$  in the cold. Needles, insol. cold water, sl. sol. ether.

*Ethyl ether*  $C_9H_7N.C(NOH).NH_2$ . [85°]. Formed from the amidoxim,  $NaOEt$ , and  $EtI$ . Needles, v. sol. alcohol and hot water.

**(Py. 3)-QUINOLYL-PROPIONIC ACID**

$C_9H_7N.OH_2.CH_2.CO_2H$ . [116°]. Formed by reducing quinolyl-acrylic acid with sodium-amalgam (Corney a. Einhorn, B. 23, 2896).

*Ethyl ether*  $EtAN$ . [116°]. Needles.

*Reference*.—OXY-QUINOLYL-PROPIONIC ACID.

**DI-(Py. 3)-QUINOLYL DISULPHIDE**

( $C_9H_7N$ ),  $S_2$ . [137°]. Formed by oxidising quinolyl-mercaptan with  $H_2O_2$  in dilute alcohol (Roos, B. 21, 622). Plates (from alcohol), insol. water and alkalis.

**QUINONE**  $C_9H_6O_2$ , i.e.  $CH.CO.CH$   
 $CH.CO.CH$  *Benzo-*

*quinone*. Mol. w. 108. [116°]. V.D. ( $H=1$ ) 53.4 (calc. 54) (Hofmann, Z. 3, 583). H.C. 659,020. H.F. 45,200 (from diamond) (Berthelot a. Recoura, B. [2] 48, 699; A. Ch. [6] 13, 312, 335; C. R. 104, 1572).

*Formation*.—1. By oxidation of quinic acid with  $MnO_2$  (4 pts.),  $H_2SO_4$  (1 pt.), and water ( $\frac{1}{2}$  pt.) (Woskresensky, A. 27, 268).—2. By

oxidation of hydroquinone (Wöhler, *A.* 51, 148).

8. By oxidation of benzidine, of aniline, and of *p*-phenylene-diamine by  $\text{MnO}_2$  and  $\text{H}_2\text{SO}_4$  (Hofmann, *Pr.* 18, 4).—4. By action of  $\text{MnO}_2$  and  $\text{H}_2\text{SO}_4$  on amido-benzene *p*-sulphonic acid and on phenol *p*-sulphonic acid (Schrader, *B.* 8, 759).

**Preparation.**—1. By adding conc.  $\text{Na}_2\text{Cr}_2\text{O}_7$  to a cold solution of aniline (1 pt.) in  $\text{H}_2\text{SO}_4$  (8 pts.) and water (25 pts.), and extracting with ether (Nietzki, *B.* 19, 1467).—2. 20 g. of aniline are dissolved in 600 c.c. of water containing 160 g. of  $\text{H}_2\text{SO}_4$ ; 20 g. of finely-powdered potassium bichromate are added by degrees, with constant agitation, keeping the temperature at  $10^\circ$ – $15^\circ$ . After standing over night 33 g. more potassium bichromate are added; the quinone is then extracted with ether, dried over  $\text{CaCl}_2$ , and the ether removed by distillation. The yield is about 86 p.c. of the theoretical amount (Schniter, *B.* 20, 2283; cf. Seyda, *B.* 16, 687; Nietzki, *B.* 11, 1102; *A.* 215, 127).—3. From *p*-amido-phenol. *p*-Amido-phenol sulphate is dissolved in water, some  $\text{H}_2\text{SO}_4$  added, and then  $\text{PbO}_2$  gradually, with shaking, till the violet colour first formed disappears. The quinone is extracted with ether. Yield theoretical (Schmitt a. Siepermann, *J. pr.* [2] 19, 317).

**Properties.**—Yellow monoclinic prisms (from water) or plates (from EtI) (Hesse, *A.* 114, 299), or needles (by sublimation). Its odour is characteristic. V. sl. sol. cold water, m. sol. alcohol and ether. The solutions turn the skin brown. Sol.  $\text{HClAq}$  and conc.  $\text{HNO}_3$ . Its alkaline solution turns brown in air (Laurent, *C. R.* 26, 35). An alcoholic solution of hydrocæroligone deposits, even in dilute solutions, crystals of cæroligone with steel-blue reflex.

**Reactions.**—1. Chlorine forms tri-chloro-quinone.—2.  $\text{HCl}$  and  $\text{KClO}_3$  give tetra-chloro-quinone (Hofmann, *A.* 52, 55).—3. Conc.  $\text{HClAq}$  forms chloro-hydroquinone (Wöhler; Städeler, *A.* 69, 808).—4.  $\text{HIAq}$  forms quinhydrone and hydroquinone.—5.  $\text{HBr}$  passed into a solution in chloroform ppts. quinhydrone, and finally forms bromo-hydroquinone.  $\text{HBrAq}$  forms, on heating di-bromo-hydroquinone (Sarauw, *A.* 209, 99).—6. Bromine. (1 mol.) in  $\text{CHCl}_3$  is instantly absorbed. Excess of bromine (2 mols.) appears to form  $\text{C}_6\text{H}_2\text{Br}_2\text{O}_2$ , which is split up by heat into  $\text{HBr}$  and two di-bromo-quinones  $\text{C}_6\text{H}_2\text{Br}_2\text{O}_2$  [2:5:4:1] and [2:6:4:1] (Nef, *J. pr.* [2] 42, 167).—7.  $\text{HNO}_3$  on heating yields oxalic and picric acids and  $\text{HCy}$  (Nietzki, *A.* 215, 138).—8. Ammonia gas forms emerald-green quinonimide  $\text{C}_6\text{H}_4\text{N}_2\text{O}$ , sol. water, the solution soon turning black (Wokresensky).  $\text{NH}_3$  in presence of chloroform produces hydroquinone, quinhydrone, and brown  $\text{C}_6\text{H}_4\text{NO}_2$  (Zincke, *B.* 16, 1556).—9. An alcoholic solution exposed to sunlight yields hydroquinone and aldehyde (Ciamician, *G.* 16, 111).—10. *Hydrazine hydrate* gives hydroquinone and a compound  $\text{C}_6\text{H}_4(\text{OH})_2\text{N}_2\text{H}_4$  (Curtius a. Thun, *J. pr.* [2] 44, 191).—11. Heated in a sealed tube alone at  $160^\circ$ , or with water at  $100^\circ$ , it yields hydroquinone and quinhydrone (Scheidt, *A.* 218, 227).—12.  $\text{PCl}_5$  forms a thick oily product,  $\text{C}_6\text{H}_4\text{O}_2\text{P}_2\text{Cl}_4$ . Water acting upon this forms mono- and di-chloro-hydroquinone.—13. Heated with  $\text{POCl}_3$ , quinone gives mono- and di-chloro-hydroquinone. An amorphous body  $\text{C}_{11}\text{H}_7\text{O}_{11}$

is also formed.—14. Alcoholic  $\text{H}_2\text{S}$  form  $\text{C}_{12}\text{H}_8\text{S}_2\text{O}_2$ , a yellowish crystalline mass, melting below  $100^\circ$ .—15.  $\text{AcCl}$  forms in the cold the di-acetyl derivatives of chloro-hydroquinone. On warming it also forms  $\text{C}_6\text{H}_4\text{O}_2(\text{OAc})_2$  (Schulz, *B.* 15, 652).  $\text{AcBr}$ , in like manner, gives  $\text{C}_6\text{H}_4\text{Br}(\text{OAc})_2$  and  $\text{C}_6\text{H}_2\text{Br}_2(\text{OAc})_2$ .—16.  $\text{Ac}_2\text{O}$  does not act below  $200^\circ$ , when it forms  $\text{C}_6\text{H}_4(\text{OAc})_2$  and a brown mass. 17. Cold dilute  $\text{NaOAc}$  converts it into hydroquinone (Hesse, *A.* 220, 365).—18. Aniline in boiling alcoholic solution forms di-phenyl-di-amido-quinone and hydroquinone  $3\text{C}_6\text{H}_4\text{O}_2 + 2\text{NH}_2\text{Ph} = \text{C}_6\text{H}_4(\text{NHPh})_2\text{O}_2 + 2\text{C}_6\text{H}_4(\text{OH})_2$ . Other primary and secondary bases act in like manner.—19. *o*- and *p*-Nitro-aniline form red crystals  $\text{C}_6\text{H}_4\text{O}_2\text{C}_6\text{H}_4(\text{NO}_2)_2\text{NH}_2$ , melting at  $97^\circ$  and  $120^\circ$  respectively (Hebebrand, *B.* 15, 1976). *o*-Nitro-aniline in  $\text{HOAc}$  forms  $\text{C}_6\text{H}_4\text{O}_2(\text{NH}_2\text{C}_6\text{H}_4\text{NO}_2)_2$  [1:4:2:5] [305°] crystallising from alcohol in red needles (Leicester, *B.* 23, 2794).—20. *o*-Amido-phenol in hot alcohol forms a base ( $\text{C}_{12}\text{H}_{18}\text{N}_2\text{O}_4$ ?) which crystallises in violet needles [250°], sl. sol. alcohol (Zincke a. Hebebrand, *A.* 226, 61). In dilute acids it forms a red solution.  $\text{Ac}_2\text{O}$  yields  $\text{C}_{12}\text{H}_{16}\text{Ac}_2\text{N}_2\text{O}_4$  [285°], while  $\text{Bz}_2\text{O}$  at  $150^\circ$  gives  $\text{C}_{12}\text{H}_{16}\text{Bz}_2\text{N}_2\text{O}_4$  [265°]. Yields a crystalline nitrosoamine  $\text{C}_{12}\text{H}_{16}(\text{NO})_2\text{N}_2\text{O}_4$ . Forms the salts  $\text{B}^+\text{H}_2\text{Cl}_4^-$ , crystallising in needles with green lustre,  $\text{B}^+\text{H}_2\text{SO}_4^-$ ,  $\text{B}^+\text{H}_2\text{PtCl}_6^-$ , and a picrate crystallising in steel-blue needles [236°].—21.  $\text{C}_6\text{H}_4(\text{NH}_2)(\text{OMe})$  [1:2] forms  $\text{C}_{20}\text{H}_{18}\text{N}_2\text{O}_4$ , or  $\text{C}_6\text{H}_4\text{O}_2(\text{NH}_2\text{C}_6\text{H}_4\text{OMe})_2$ , crystallising in reddish-violet needles [230°], forming a blue solution in  $\text{H}_2\text{SO}_4$ .—22. *p*-Amido-phenol hydrochloride gives  $\text{C}_6\text{H}_4\text{O}_2(\text{NH}_2\text{C}_6\text{H}_4\text{OH})_2$ , crystallising in violet-brown needles, not melted at  $290^\circ$ .—23. (1,3,2)-Amido-*o*-cresol forms a compound [285°], which gives a crystalline acetyl-derivative.—24. (2,4,1)-Nitro-toluidine forms  $\text{C}_6\text{H}_4\text{O}_2\text{NH}_2\text{C}_6\text{H}_4\text{NO}_2$ , decomposing at  $300^\circ$ , and  $\text{C}_6\text{H}_4\text{O}_2(\text{NH}_2\text{C}_6\text{H}_4\text{NO}_2)_2$  (L.).—25. Acetoacetic ether and  $\text{ZnCl}_2$  at  $100^\circ$  form  $\text{C}_{14}\text{H}_{16}\text{O}_4$  [184°], crystallising in needles, insol. water, sol. hot alcohol. Conc.  $\text{H}_2\text{SO}_4$  forms a deep-blue solution. Alcoholic potash forms  $\text{C}_{14}\text{H}_{16}\text{K}_2\text{O}_4$  2aq, the salt of an insoluble acid  $\text{C}_{14}\text{H}_{12}\text{O}_6$  (Von Pechmann, *B.* 21, 3005).—26.  $\text{C}_6\text{H}_4(\text{OH})(\text{OMe})$  [1:4] in hot ligroin forms di-methyl-quinhydrone  $\text{C}_{20}\text{H}_{20}\text{O}_6$ , crystallising in lustrous greenish-black prisms, decomposed by warm water (Hesse, *A.* 200, 253).

Mol. w. 123.

**Formation.**—1. By boiling nitroso-di-methyl-aniline (or nitroso-di-phenyl-aniline) hydrochloride with dilute  $\text{NaOHAq}$  (Baeyer a. Caro, *B.* 7, 809, 967; Ter Meer, *B.* 8, 622; Fischer, *B.* 19, 2995).—2. By adding  $\text{KNO}_2$  and  $\text{HOAc}$  to an aqueous solution of phenol (B. a. C.; cf. Stenhouse a. Groves, *A.* 188, 360).—3. By adding hydroxylamine hydrochloride to a cold dilute aqueous solution of quinone (Goldschmidt, *B.* 17, 213).—4. Formed also from aqueous phenol, hydroxylamine hydrochloride and  $\text{H}_2\text{O}_2$  (Wurster, *B.* 20, 2631). Free hydroxylamine merely reduces quinone to hydroquinone.

**Properties.**—Nearly colourless needles or greenish trimetric plates; *a:b:c* = 598:1:2.469. M. sol. water, forming a light-green solution

which turns brown on boiling. **V.** sol. ether, acetone, and aqueous alkalis, sl. sol. HOAc. Decomposes at 120°–130°. Decomposed by hot conc. HClAq. When dissolved in phenol it gives, on addition of H<sub>2</sub>SO<sub>4</sub>, a cherry-red solution turned blue on addition of KOHAq. In this reaction the compound C<sub>12</sub>H<sub>11</sub>NO<sub>4</sub> is formed. Polyhydric phenols, containing two hydroxyls in the *m*-position, give by like treatment fluorescent 'dichroins'; thus resorcin gives C<sub>12</sub>H<sub>11</sub>NO<sub>4</sub>, C<sub>12</sub>H<sub>11</sub>N<sub>2</sub>O<sub>10</sub>, and azoresorcin (Brunner & Chuit, B. 21, 249).

**Reactions.**—1. Oxidised by alkaline K<sub>2</sub>FeCy<sub>4</sub> to *p*-nitro-phenol.—2. Reduced by tin and HClAq to *p*-amido-phenol.—3. Nitrous acid gas passed into an ethereal solution forms diazo-phenol nitrate (Jaeger, B. 8, 894).—4. Gaseous HCl passed into a cooled ethereal solution forms di-chloro-amido-phenol [175°] and tri-chloro-amido-phenol (J.; Hirsch, B. 13, 1908).—5. A solution of HCl in MeOH in presence of ice forms C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>(NH<sub>2</sub>)(OMe) [72°]; while EtOH and HCl give C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>(NH<sub>2</sub>)(OEt) [46°] (275°). 6. Conc. KOHAq at 180° forms azophenol C<sub>12</sub>H<sub>11</sub>N<sub>2</sub>O<sub>2</sub> [214°] (Jaeger).—7. KClO<sub>3</sub> and HClAq form C<sub>6</sub>H<sub>4</sub>ClNO<sub>2</sub>, crystallising in yellow needles, v. sol. alcohol, insol. water, and exploding at 70° (Möhlau, B. 19, 281).—8. ClO<sub>3</sub>.Me added to its sodium salt forms C<sub>6</sub>H<sub>4</sub>(NO)<sub>2</sub>O.CO<sub>2</sub>Me [137°], while ClCO<sub>2</sub>Et yields C<sub>6</sub>H<sub>4</sub>(NO)<sub>2</sub>O.CO<sub>2</sub>Et [109°] (Walker, B. 17, 400). 9. BzCl added to the sodium salt in ether forms C<sub>6</sub>H<sub>4</sub>(NO)<sub>2</sub>OBz, crystallising in yellowish needles [168°–175°], sol. hot alcohol (Walker).—10. Aniline forms azophenine C<sub>6</sub>H<sub>4</sub>(NPh)<sub>2</sub>(NHPH)<sub>2</sub>, *p*-Chloro-aniline forms, in like manner, tetra-chloro-azophenine [265°] (Fischer & Hepp, B. 21, 677).—11. Bromine forms C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub>O(NOH), crystallising in small leaflets, decomposed by water (O. Fischer, B. 21, 674).—12. Phenyl cyanate gives C<sub>6</sub>H<sub>4</sub>O.NO.CO.NHPH, crystallising in short yellow prisms decomposed at 160° without melting. It is converted by alkalis into the oxim, aniline, and CO<sub>2</sub> (Goldschmidt & Straus, B. 22, 3105).

**Salts.**—C<sub>6</sub>H<sub>4</sub>(NO)(ONa) 2aq. Red needles (from alcohol), v. sol. water, insol. ether. Decomposed by boiling water. Ppd. by NaOH from aqueous solution.—(C<sub>6</sub>H<sub>4</sub>(NO)<sub>2</sub>)<sub>2</sub>Ba (dried at 100°). Red needles (from warm water).—C<sub>6</sub>H<sub>4</sub>(NO)<sub>2</sub>OAg aq. Violet crystals with green reflex.

**Dioxim** C(NO<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>C(NO<sub>2</sub>)<sub>2</sub> Formed by the action of hydroxylamine hydrochloride on the mono-oxim, on hydroquinone, and on *p*-nitroso-aniline (Nietzki, B. 20, 613; 21, 430; Fischer, B. 21, 685). Yellowish needles (from hot water). Decomposes at 240°. Reduced by SnCl<sub>4</sub> and HCl to *p*-phenylene-diamine. Oxidised by alkaline K<sub>2</sub>FeCy<sub>4</sub> into insoluble di-nitroso-benzene. Ac<sub>2</sub>O forms a crystalline di-acetyl derivative, sol. hot alcohol.

**Quinone-chlorimide** C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>NCl. [85°].

Formed by the action of bleaching powder on a solution of the hydrochloride of *p*-amido-phenol (R. Schmitt, J. pr. [2] 8, 1; 19, 816; Hirsch, B. 11, 1980; 13, 1903; Fogh, B. 21, 890; Andresen, J. pr. [2] 23, 167) or C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>OEt. Purified by steam-distillation. Golden crystals (from HOAc).

Sl. sol. cold water, v. sol. alcohol and ether. Explodes above 86°. Smells like quinone. Stains the skin brown. Turned brown by alkalis. Reduced by tin and HCl to *p*-amido-phenol. Water at 100° forms quinone. Aqueous SO<sub>2</sub> forms amido-phenol sulphonic acid. HCl gives chlorinated amido-phenols. Gives Liebermann's colour reaction with phenol and H<sub>2</sub>SO<sub>4</sub>.

**Quinone-di-chlorimide** C<sub>6</sub>H<sub>4</sub>N<sub>2</sub>Cl<sub>2</sub> i.e.

C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>NCl<sub>2</sub> Formed from *p*-phenylene-diamine hydrochloride and bleaching-powder solution (Krause, B. 12, 47). Needles (from water), decomposing at 124°. Almost insol. cold water. Its solution stains the skin brown. Reduced by SnCl<sub>4</sub> to *p*-phenylene-diamine. HCl forms tetra-chloro-*p*-phenylene-diamine. Br gives di-chloro-di-bromo-quinone. (8)-Naphthylamine forms amido-naphthophenazine. (8)-Naphthol forms C<sub>12</sub>H<sub>11</sub>N<sub>2</sub>O, which dyes silk crimson and yields B'HNO<sub>2</sub> (Nietzki & Otto, B. 21, 1745).

**Quinone-phenylimide** C<sub>12</sub>H<sub>11</sub>NO i.e.

C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>N<sup>Ph</sup>O [97°]. Formed by oxidising *p*-oxy-di-phenyl-amine in benzene by HgO (Bandrowski, M. 9, 134, 415). Red crystals, v. sol. alcohol, ether, and chloroform. Decomposed by water and alkalis. Acids reproduce quinone. Reacts with aniline, forming *p*-oxy-di-phenyl-amine and di-phenyl-di-amido-quinone-phenylimide.

**Quinone-*p*-tolylimide** C<sub>13</sub>H<sub>11</sub>NO. [70°]. Formed in like manner from *p*-oxy-phenyl-*p*-tolyl-amine (B.). Dark-red scales (from ligroin), sol. most solvents.

**Di-methyl-amido-phenylimide** C<sub>14</sub>H<sub>11</sub>N<sub>2</sub>O i.e.

C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>N(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>O Phenol-blue. Formed by the action of nitroso-di-methyl-aniline on an alkaline solution of phenol, or by oxidation of a mixture of phenol and phenylene-di-methyl-*p*-diamine (Möhlau, B. 16, 2851; 18, 2913). Formed also from quinone-chlorimide and di-methyl-aniline (Fogh, B. 21, 889). Steel-blue prisms (from water) (containing 1/2 aq). Its solution in HClAq is blue. Conc. H<sub>2</sub>SO<sub>4</sub> forms quinone and C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>(NMe<sub>2</sub>)<sub>2</sub>. Boiling NaOHAq forms NMe<sub>2</sub>H and C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>N(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>OH. The sulphonic acid C<sub>14</sub>H<sub>11</sub>N<sub>2</sub>SO<sub>3</sub> 1/2 aq, formed from *p*-amido-phenol-sulphonic acid in water by successive treatment with Cl and dimethylaniline, crystallises in bronzed needles, forming a blue solution in NaOHAq.

**Quinone tetrahydride** CO<CH<sub>2</sub>CH<sub>2</sub>>CO.

**Diketohexamethylene.** [78°]. Formed by heating the dihydride of di-oxy-terephthalic acid (succinyl-succinic acid) of 200° and distilling the product under reduced pressure (Hermann, A. 211, 322; Baeyer & Noyes, B. 22, 2170). Prisms, v. sol. water. FeCl<sub>3</sub> does not colour its solution. Its alkaline solution turns brown in the air. Bromine forms C<sub>6</sub>Br<sub>2</sub>O<sub>2</sub>. Reduces Fehling's solution. HCy forms C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>Cy<sub>2</sub> [180°]. Yields a di-oxim which when quickly heated melts at 200°; when slowly heated at 192°. The di-phenyl-di-hydrazide C<sub>6</sub>H<sub>4</sub>(N<sub>2</sub>HPh)<sub>2</sub> is obtained as a white pp. [125°] crystallising from alcohol in yellow prisms [150°], yielding a crystalline hydrochloride B'H<sub>2</sub>Cl.

An isomeride of the tetrahydride  $C_6H_4O_2$ , [170°], is got by the action of NaOHaq on succinyl-succinic ether. It crystallises in prisms (containing  $\frac{1}{2}$  aq). It changes into the preceding isomeride on distillation. It reduces Fehling's solution.

References.—AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, CHLORO-NITRO-, IODO-, NITRO-AMIDO-, OXY-AMIDO-, and OXY-QUINONE.

TRIQUINONE v. BENZENE-TRI-QUINONE.  
QUINONE DICARBOXYLIC ACID; *dihydride* v. DI-OXY-TEREPHTHALIC ACID.

Tetrahydride v. Dihydride of DI-OXY-TEREPHTHALIC ACID.

Quinone tetracarboxylic acid. *Methyl ether*  $C_6O_4(CO_2Me)_4$ , [207°]. Formed by oxidation of  $C_6(OH)_2(CO_2Me)_4$  with  $HNO_3$  (Nef, A. 258, 818). Colourless prisms (containing 2MeOH) (from MeOH) or yellow needles (by sublimation).

*Ethyl ether*  $C_6O_4(CO_2Et)_4$ , [149°]. Formed by oxidising di-amido-pyromellitic ether with conc.  $HNO_3$  (Nef, C. J. 53, 428; A. 237, 28). Golden needles (from alcohol). May be sublimed. On treatment with KOHAq or with  $H_2SO_4$  in HOAc it yields hydroquinone tetracarboxylic ether. Zinc-dust and HOAc also reduce it to hydroquinone tetracarboxylic ether.

QUINOPHENOL v. OXY-QUINOLINE.

DIQUINO-PHENAZINE  $C_{12}H_8\langle\begin{smallmatrix} N \\ N \end{smallmatrix}\rangle C_6O_4$ .  
Formed by the action of dilute  $HNO_3$  on  $C_6H_2N_2C_6O_4(OH)_2$ , which is got from rhodizonic acid and o-phenylene-diamine (Nietzki a. Schmidt, B. 21, 1228). Yellowish needles (containing  $\frac{3}{4}$  aq), sl. sol. water. Converted by o-phenylene-diamine sulphate into  $C_{21}H_{12}N_4$ , crystallising in greenish needles.

DIQUINOQUINONE  $CH\langle\begin{smallmatrix} CO.CO \\ CO.CO \end{smallmatrix}\rangle CH$ . *Di-quinoyl*. The di-oxim  $C_{12}H_4O_4(NOH)_2$  is dinitrosoresorcin (*q. v.*) (Goldschmidt a. Strauss, B. 20, 1611; Kehrman a. Messinger, B. 23, 2816). The dioxim is converted by hydroxylamine into the tetra-oxim, which, on heating with  $Ac_2O$ , yields the anhydride  $C_{12}H_4N_4O_2$ , crystallising in needles [61°], sol. ether. The tetra-oxim may be reduced by  $SnCl_2$  and HCl to tetra-amido-benzene.

Triquoquinone v. BENZENE TRIQUINONE.  
Reference.—OXY-DIQUINOYL.

DIQUINO-TOLAZINE  $C_6H_3Me\langle\begin{smallmatrix} N \\ N \end{smallmatrix}\rangle C_6O_4$ .  
Formed from rhodizonic acid and tolylene-o-diamine, the product being oxidised by  $HNO_3$  (Nietzki a. Kehrman, B. 20, 324). Yellow needles (containing 2aq). On warming with an aqueous solution of a salt of tolylene-o-diamine it is converted into  $C_{12}H_4N_4O_2$ , which crystallises from chloroform in needles (containing  $CHCl_3$ ).

QUINOVATANNIC ACID  $C_{16}H_{18}O_7$ . Occurs in the bark of *Cinchona nova* (*Quina nova*) (Hlasiwetz, A. 79, 129). Translucent yellow mass, sol. water and alcohol, insol. ether.  $FeCl_3$  gives a dark-green colour.  $NH_4Aq$  colours its solution brown. Its alkaline solution absorbs oxygen from the air. Boiling dilute  $H_2SO_4$  splits it up into sugar and 'quinova red'  $C_{28}H_{38}O_{12}$  (Rembold, A. 143, 278), which also occurs in the bark. Quinova red is a nearly black resin, nearly insol. water, v. sol. alcohol, ether, and alkalis,

gives no colour with  $FeCl_3$ , and yields proto-catechuic acid on fusion with potash.

QUINOVIN  $C_{20}H_{18}O_6$  (Hlasiwetz) or  $C_{20}H_{18}O_{11}$  (Oudemans, jun., R. T. C. 2, 160). *Quinova-bitter*. *Quinovic acid*.  $[a]_D = +59^\circ$ . Occurs in false cinchona bark from *Cinchona nova* (Pelletier a. Caventon, J. Ph. 7, 112; Winckler, Rep. Pharm. 51, 193; Buchner, jun., A. 17, 161; Peterson, A. 17, 165; Schnedermann, A. 45, 277; Rochleder a. Hlasiwetz, A. 79, 129; 111, 182). Occurs also in true cinchona bark (Schwarz, A. 80, 330; De Vrij, J. Ph. [3] 37, 255), in all parts of *Cinchona Calisaya* (from Java), and in tormentilla root (Rembold, A. 145, 9).

Preparation.—The bark is extracted with boiling milk of lime, the extract ppd. by HCl, and the pp. repeatedly dissolved in alcohol and thrown down by water.

Properties.—Needles (from alcohol), almost insol. hot water, v. sl. sol. ether, v. sol. dilute alcohol. Tastes bitter. Dextrorotatory. Sol. aqueous alkalis. Resolved by acids into quinovic acid and quinovite. Does not reduce Fehling's solution.

Salts.— $PbC_{20}H_{18}O_6aq$ .— $(CuO)_4C_{20}H_{18}O_6$ .  
(8)-Quinovin.  $[a]_D = +28^\circ$  in a 2-7 p.c. alcoholic solution. Occurs in cuprea bark (from *Remijia*) (Lieberrmann a. Giesel, B. 16, 923). Scales (from dilute alcohol). Insol. ether, v. e. sol. alcohol. Dextrorotatory. Forms with alcohol the compound  $C_{20}H_{18}O_{11}5EtOH$ , crystallising in large prisms. Split up by dilute acids into quinovic acid and quinovite.

Quinovite  $C_{20}H_{18}O_{11}$ , i.e.  $C_{20}H_{18}O(OH)_3$ . *Quinova-sugar*. (c. 300°).  $[a]_D = 60^\circ$  (0.);  $= +78^\circ$  (l. a. G.). Formed by the action of HCl on a hot alcoholic solution of quinovin; quinovic acid crystallises out, and the mother-liquor is neutralised by  $BaCO_3$ , filtered, and evaporated. Hygroscopic mass, sol. ether. Has a bitter-sweet taste. Does not ferment with yeast. Reduces Fehling's solution.

Tri-acetyl derivative  $C_{20}H_{18}O(OAc)_3$ . [47°]. (c. 303°). White needles (Lieberrmann, B. 17, 872).

Quinovic acid  $C_{20}H_{18}O_6$  (Oudemans, R. T. C. 2, 160);  $C_{20}H_{18}O_6$  (Hlasiwetz a. Gilm, A. 111, 182);  $C_{20}H_{18}O_6$  (Lieberrmann).  $[a]_D = +86^\circ$ . Occurs in tormentilla root (Rembold, A. 145, 6). Formed from quinovin as above. White sandy powder composed of minute trimetric six-sided laminae, insol. water, v. sol. hot alcohol, sl. sol. ether. Tasteless. Ppd. from alkaline solutions by acids in a gelatinous form, gradually becoming pulverulent. Dextrorotatory.  $H_2SO_4$  gives off CO and forms novic acid, quinochromin  $C_{20}H_{18}O_8$  (crystallising in needles), quinovene  $C_{20}H_{12}$  (?), and apoquinovic acid  $C_{16}H_{18}O_4$  (crystallising in needles; whence  $C_{16}H_{18}NaO_4\frac{1}{2}aq$ ).

Salts.— $K_2C_{20}H_{18}O_6$ ,  $1\frac{1}{2}aq$ ; bulky pp.— $CuA^*Cu_2(OH)_5aq$ ; light-blue pp.— $Ag_2A^*$ ; bulky pp.

*Ethyl ether*  $C_{20}H_{18}O_6Et_2O$ . [127°–130°]. Crystals, v. sol. alcohol and ether.

Pyroquinovic acid  $C_{31}H_{30}O_8$  (above 360°). Formed by heating quinovic acid (Lieberrmann a. Giesel, B. 16, 936). Needles, insol. water, v. sol. alcohol and ether. Its alkaline solution is levorotatory. On distillation, the distillate solidifies to a clear glassy mass, easily soluble in ether, and resembling gum copal in its proper-

ties. When this substance is heated with HI and P it yields a terpene (quinoterpene) which probably has the formula  $C_{20}H_{34}$ . This terpene is also formed by direct reduction of pyroquinovic acid with HI and P (Liebemann, *B.* 17, 869).

Salts.—KA' (dried at 110°).—BaA'.

Quinoterpene  $C_{20}H_{34}$ . (above 360°). Formed as above. Dextrorotatory.

Oxy-quinoterpene  $C_{20}H_{32}O_2$  or  $C_{20}H_{34}O$ . *Cholestol*. [139°]. (above 360°). Accompanies quinovin in false cinchona bark (Liebemann, *B.* 17, 871; 18, 1803; Hesse, *A.* 234, 377). Needles (from alcohol). Reduced by HI and P to quinoterpene. Yields an acetyl derivative [126°] and a benzoyl derivative [144°].

QUINOXALINE  $C_8H_4N_2$  i.e.  $C_6H_4 \begin{smallmatrix} \text{N:CH} \\ \text{N:CH} \end{smallmatrix}$

[27°]. (222° uncor.). Formed by the action of o-phenylene-diamine on glyoxal in aqueous solution (Hinsberg, *B.* 17, 320; *A.* 287, 334). White crystals, smelling like quinoline and piperidine, miscible with cold water, alcohol, ether, and benzene. Partially separated from aqueous solution by warming or by adding KOHAq. Its aqueous solution gives white pps. with  $HgCl_2$  and  $AgNO_3$ . Yields a sparingly soluble oxalate. Little attacked by oxidising agents. Sodium reduces it, in alcoholic solution, to phenylene-ethylene-diamine (Merz a. Ris, *B.* 20, 1190).— $B'HCl$ : needles, v. sol. water. Decomposes at 184°.— $B'H_2SO_4$ . [187°]. Silvery plates, v. sol. water.— $B'H_2PtCl_6$  (dried at 100°). Needles.

References.—AMIDO- and OXY-QUINOXALINE.

## R

RACEMIC ACID v. TARTARIC ACID.

RACEMIC CAMPHOR v. CAMPHOR.

RADICLE. Lavoisier and his followers regarded an acid as a substance formed by the combination of much oxygen with another body; the body with which the oxygen was combined was called by de Morveau the radicle of the acid, and the name was used in this sense by Lavoisier. 'Il faut donc distinguer dans tout acide la base acidifiable, à laquelle M. de Morveau a donné le nom de radical, et le principe acidifiant, c'est-à-dire, l'oxygène' (*Traité élémentaire de Chimie* [1789] 1, 69). That the radicle of an acid might be either a simple or a compound substance is evident from de Morveau's use of the term; in speaking of the nomenclature of acids of unknown composition, he says: 'Nous nous sommes contentés de désigner l'être simple qui y modifie l'oxygène par l'expression de base acidifiable, ou, pour abréger, de radicle, de tête acide' (*Mémoire sur le Développement des Principes de la Nomenclature Méthodique* [1787]). Lavoisier, in 1789, extended the meaning of the term radicle when he said (*Traité*, 1, 209) that most of the oxidisable and acidifiable radicles of mineral compounds were simple bodies, whereas the radicles of compounds of vegetable and animal origin were generally composed of at least two simple bodies. The notion of radicles was here, and elsewhere, extended by Lavoisier to mean the bases or foundations whereon more complicated bodies were built up, generally by the addition of oxygen.

As organic chemistry advanced, and many compounds were obtained from animal and vegetable sources, attempts were naturally made to find some reason for the existence of so vast a number of compounds all composed of but three or four elements. Lavoisier's assertion that the radicles of organic compounds are themselves composed of two or more elements, was revived, adopted, and developed. Berzelius, Liebig, Dumas, and other earlier workers in organic chemistry were struck by the enormous number of compounds produced by the union

of the four elements carbon, hydrogen, oxygen, and nitrogen. They said the true elements of organic chemistry are the radicles cyanogen, amidogen, benzoyl, ethyl, &c., &c. Dumas (*C. R.* 5, 300) said: 'In mineral chemistry the radicles are simple, in organic chemistry they are compound; therein consists the whole difference. The laws whereby the compounds are formed and their reactions are regulated are the same in both.' Liebig said: 'Organic chemistry is the chemistry of compound radicles.' In 1832 Liebig and Wöhler made apparent the meaning and wide applicability of the dictum that 'organic chemistry is the chemistry of compound radicles' by their researches into the constitution of the compounds obtained from oil of bitter almonds. By regarding these bodies as compounds of the radicle benzoyl,  $C_7H_5O$ , they became comparable with the compounds of the radicles potassium and other metals. From this time the conception of the radicle was firmly established.

The elements are the simple radicles, on which, and by the combinations of which, compounds are built up. The reactions of a series of compounds often show such similarities that we are obliged to conclude that the compositions of these compounds are also similar; in many cases this similarity of composition can be made apparent only by supposing that a certain group, or collocation, of elements enters into the composition of all the compounds. Such a group of elements, playing the part of a simple body throughout a series of reactions, but nevertheless separable into two or more elements, is called a compound radicle.

For an example of the working out of the conception of the radicle v. AMMONIUM COMPOUNDS, vol. i. pp. 200-201.

M. M. P. M.

RADI OIL. The product of the distillation of the wood of a juniper. Contains a sesquiterpene  $C_{15}H_{22}$ , whose hydrochloride  $C_{15}H_{21}Cl$  melts at 118° (Wallach, *A.* 238, 82).

RAFFINOSE  $C_{18}H_{34}O_{16}$  5aq (Morris a. Brown, *C. J.* 53, 619; De Vries, *R. T. C.* 8, 326; *C. R.*

106, 751; Tollens a. Mayer, *B.* 21, 1569). *Melitose*. *Gossypose*. *Melittose*. Mol. w. 528 to 644 (by Raoult's method) (cal. 594); 596 (by rate of osmosis in leaves of *Tradescantia*). [ $\alpha$ . 87°]. S. 17 at 16° (B.); 14 at 20° (Loiseau). S. (80 p.c. alcohol) 1.4 at 70°. [ $\alpha$ ]<sub>D</sub> = 104.6 (M. a. B.). [ $\alpha$ ]<sub>D</sub> = 116.6. H.C. 2,019,700 (Stohmann, *J. pr.* [2] 45, 320; cf. Berthelot a. Matignon, *C. R.* 111, 18). Discovered by Johnston (*C. S. Mem.* 1, 159) in a manna, which drops from various kinds of eucalyptus in Tasmania. Further examined by Berthelot (*C. R.* 41, 392) and Rischbiet a. Tollens (*B.* 18, 2611). Occurs also in cotton-seed (Ritthausen, *J. pr.* [2] 29, 351; Böhm, *J. pr.* [2] 30, 37), in beet-root molasses (Loiseau, *Bl.* [2] 26, 365; Tollens, *B.* 18, 26; A. 232, 201; Lipmann, *B.* 18, 3087; Lindet, *C. R.* 110, 795; *Bl.* [3] 8, 682).

*Preparation*.—Cotton-seed cake is extracted with spirit (S.G. 848). The extract is boiled down to a small bulk, and then shaken with ether (to remove colouring matters). After a time lumps of sugar separate; these are dissolved in 80 p.c. alcohol at 70°, boiled with animal charcoal, and allowed to stand. In a week glittering needles, arranged in hemispherical masses, separate (H. Ritthausen, *J. pr.* [2] 29, 351).

*Properties*.—Groups of needles, v. c. sol. hot water, v. sl. sol. alcohol. Has a slightly sweet taste. Does not reduce Fehling's solution. Not turned brown by boiling KOHAq. At 108° it gives off its water of crystallisation without melting; the anhydrous raffinose is not very hygroscopic. A second hydrate (containing 6aq) may be got as lamellae by crystallisation from dilute alcohol (Berthelot, *C. R.* 109, 548; *Bl.* [3] 2, 656). Readily ferments, giving with good yeast approximately as much alcohol as cane-sugar, while with feeble yeast only one-third of that quantity is formed. Raffinose can be assimilated by young plants, being converted into starch (Brown a. Morris, *C. J.* 57, 486).

*Reactions*.—1. Boiling dilute H<sub>2</sub>SO<sub>4</sub> splits it up into lavalulose and 'melibiose' C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>, which yields with phenyl-hydrazine the osazone C<sub>22</sub>H<sub>32</sub>N<sub>4</sub>O<sub>8</sub>. The mixture of lavalulose and melibiose shows [ $\alpha$ ]<sub>D</sub> = 50°. On further boiling with dilute H<sub>2</sub>SO<sub>4</sub> the melibiose is hydrolysed, the product consisting of galactose (1 mol.), lavalulose (1 mol.), and dextrose (1 mol.) (Scheibler a. Mittelmeier, *B.* 22, 1678, 3118; Tollens, *A.* 238, 808; 249, 227). Melibiose is identical with eucalyn, and may be reduced by sodium-amalgam to melibiotite C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>, a syrup which does not reduce Fehling's solution, but yields galactose on boiling with dilute acids. Invertin also splits up raffinose first into lavalulose (which may be fermented by yeast) and melibiose, and then this melibiose may be split up at 36° by a conc. solution of invertin into dextrose and galactose. The *Pneumococcus* of Friedländer sets up fermentation in suitable solutions of raffinose (Percy Frankland, *C. J.* 59, 270).—2. NaOEt gives a compound containing 6 to 7 p.c. sodium.—3. Boiling HNO<sub>3</sub> (S.G. 1.15) gives 23 p.c. of mucic acid. Saccharic acid is also formed.

*Salts* (Beythien a. Tollens, *A.* 255, 195).—NaC<sub>12</sub>H<sub>21</sub>O<sub>10</sub>.—Na<sub>2</sub>C<sub>12</sub>H<sub>20</sub>O<sub>10</sub>.aq. Crystals.—C<sub>12</sub>H<sub>20</sub>O<sub>10</sub>(SrO)<sub>2</sub>.aq. Sl. sol. water.—C<sub>12</sub>H<sub>20</sub>O<sub>10</sub>.SrO.

—C<sub>12</sub>H<sub>21</sub>O<sub>10</sub>.BaO.—C<sub>12</sub>H<sub>20</sub>O<sub>10</sub>.2BaO. Crystals.—C<sub>12</sub>H<sub>20</sub>O<sub>10</sub>(CaO)<sub>2</sub>.2aq.—C<sub>12</sub>H<sub>20</sub>O<sub>10</sub>.3PbO.

*Estimation*.—In a mixture of cane-sugar and raffinose, the amount of raffinose may be determined by observing the change of rotatory power after hydrolysis (Cretyd, *B.* 19, 3115; Gunning, *Fr.* 28, 45). The raffinose may also be pptd. by lead acetate from a solution in methyl alcohol, and the effect on the polarising action of the liquid observed (Lotman, *Chem. Zeit.* 12, 391; Gunning).

**RANGIFORMIC ACID** C<sub>11</sub>H<sub>18</sub>O<sub>9</sub>. [106°]. Occurs, together with atranoric acid, in the lichen *Cladonia rangiformis* (Paterno, *G.* 12, 259). Plates (from benzene), sol. ether. Its ammoniacal solution gives a flocculent pp. of AgA' on adding AgNO<sub>3</sub>.

**RAPIC ACID** C<sub>11</sub>H<sub>18</sub>O<sub>9</sub>. Occurs as glyceride, together with the glycerides of erucic and benenic acids, in rape-seed oil (Reimer a. Will, *B.* 20, 2387). Oil. Yields stearic acid on fusion with potash. The zinc salt melts at 78°. The Na salt is gelatinous, v. sol. water, sl. sol. alcohol.

**REDUCINE** C<sub>12</sub>H<sub>21</sub>N<sub>3</sub>O<sub>9</sub> or C<sub>12</sub>H<sub>21</sub>N<sub>3</sub>O<sub>8</sub>. An alkaloid occurring, as well as para-reducine C<sub>12</sub>H<sub>21</sub>N<sub>3</sub>O<sub>8</sub>, according to Thudichum (*C. R.* 106, 1803) in urine. It reduces ferric, cupric, mercuric, and silver salts, and forms an insoluble barium compound.

**REDUCTION**. This term is used as synonymous with deoxidation in its widest sense. v. DEOXYDATION, vol. ii. p. 377; and cf. OXIDATION, vol. iii. p. 657.

**REGIANIN** v. JUGLONE.

**RENNET** v. MILK and PROTEINS.

**RESACETIC ACID** v. vol. i. p. 18.

**RESACETOPHENONE** v. DI-OXY-ACETOPHENONE.

**RESINS**. Amorphous substances, occurring in all parts of plants, but especially in the bark (Wiesner, *Sitz. W.* 52 [2] 118). Frequently associated with essential oils. Resins are also formed from various oils by atmospheric oxidation or by the action of alcoholic potash. Boiling aqueous potash resinifies aldehydes. P<sub>2</sub>O<sub>5</sub> converts various aldehydes (e.g. benzoic aldehyde) into resins. These resins are solid, translucent, with conchoidal fracture, insol. water, wholly or partially sol. alcohol and aqueous alkalis. The resins, therefore, contain acids. The resins soften when heated, but are decomposed by distillation. By potash-fusion protocatechuic acid is obtained from guaiacum, benzoin, dragon's blood, asafetida, esparto resin, myrrh, acaroid resin, and opopanax. By potash-fusion p-oxy-benzoic acid is got from benzoin, dragon's blood, aloes, and acaroid resin; phloroglucin from dragon's blood, esparto resin, and gamboge; and resorcin from galbanum, asafetida, gum ammoniac, sagapenum, and acaroid resin (Hlasiwetz a. Barth, *A.* 134, 265; 138, 61; 139, 83). Dammar, sandarac, mastic, and incense-resin are not attacked by fused potash. Resins containing gum or mucilage, soluble in water, are called gum-resins. Resins mixed with essential oils are termed balsams. The following resins are completely soluble in alcohol of 96 p.c.: benzoin, caranna, resins and balsams from conifers (colophony), dragon's blood, guaiacum, mani-resin, mastic from Alexandria and from Bombay, black balsam of Peru,

*podocarpus* resin, sandarac, balsam of Tolu, xanthorrhoea resin. The following resins are only partially dissolved by alcohol of 95 p.c.: ammoniac, asafetida, bellium, Canada balsam, ceradial resin, copaiba balsam, copal, dammar, elemi, euphorbium, euryops resin, galbanum, gamboge, liquidambar, common mastic, Mecca balsam, myrrh, olibanum, opopanax, white balsam of Peru, sagapenum, sonora-lac, and liquid storax (Hirschsohn, *Ar. Ph.* [3] 10, 481; 11, 54, 152, 247, 312, 434). Ether dissolves completely: caranna, Canada balsam, conifer resins, copaiba balsam, dragon's blood, elemi, guaiac-resin, mani-resin, mastic, podocarpus resin, and sandarac. Most other resins are partially soluble in ether.  $\text{FeCl}_3$  gives in alcoholic solution a blue colour with guaiacum and caranna, a dark-green colour with benzoin and some sorts of asafetida, and a black colour with gamboge, balsam of Peru, opopanax, storax, sagapenum, shellac, and xanthorrhoea resin.  $\text{FeCl}_3$  gives in an alcoholic solution of Canada balsam and of some sorts of dammar, a pp. which disappears on heating, and with copal and sonora-lac a pp. which does not disappear on heating. Alcohol containing  $\text{HCl}$  is coloured brick-red by white balsam of Peru and ceradial resin; red to violet by common myrrh and euryops-resin; blue to violet by some sorts of elemi; yellowish-brown to green by guaiac-resin; yellow, changing through brown to cherry-red, by benzoin and balsam of Tolu; crimson by xanthorrhoea resin; greenish, changing to dingy violet, by asafetida; yellow by gamboge and caranna; light rose-coloured by podocarpus resin; and brown by other resins. Conc.  $\text{H}_2\text{SO}_4$  forms a cherry-red solution with benzoin from Siam and with balsam of Tolu; a yellow solution with gamboge; a solution with yellowish-brown fluorescence with asafetida; and brown with other resins. A drop of  $\text{H}_2\text{SO}_4$  added to a solution of pine-wood resin in  $\text{H}_2\text{OAc}$  gives a red or violet colour as the liquids mix (Morawski, *C. C.* 1888, 1630). Fossil resins (*e.g.* amber) are often found in beds of coal and lignite, being clearly derived from plants. Schmidt a. Erban (*M.* 7, 655; *cf.* Kremel, *Fr.* 26, 262) have determined, for a great variety of commercial resins, the quantity of alkali necessary to neutralise an alcoholic solution, and the amount required for saponification, and also the amount of iodine the resins can take up. They also base a method of separation upon the relative solubilities of resins. A classification of red resins according to their solubility in chloroform, benzene, and  $\text{CS}_2$  is given by Dobbie a. Henderson (*Tr. E.* 30, 624). Colophony softens under boiling water, while powdered shellac, mastic, elemi, and dammar agglomerate, and sandarac, copal, and amber remain unchanged (Kliebhau, *C. C.* 1888, 87). The products of distillation of colophony have been examined by many chemists (Fremy, *A. Ch.* [2] 59, 13; A. 15, 284; Pelletier a. Walter, *A. Ch.* [2] 67, 267; Thénard, Robiquet, a. Dumas, *C. R.* 1838, i. 460; Schiel, *A.* 115, 96; Couerbe, *J. pr.* 18, 165; Curie, *C. N.* 30, 189; Kelbe, *B.* 13, 1157; B. 14, 1240; A. 210, 1; B. 15, 808; Renard, *C. R.* 91, 416; B. 13, 2000; B. [2] 36, 215; Tilden, *B.* 13, 1604; Anderson, *C. N.* 20, 76; Mills, 'Destructive Distillation,' 31; Tichborne, *Ph.* [3] i. 302; Morris, *C. J.* 41,

167) by whom the following substances have been described as constituents: water, retinaphtha  $\text{C}_8\text{H}_8$  (108°) (P. a. W.), retinyl  $\text{C}_8\text{H}_8$  (150°) (P. a. W.), retinol  $\text{C}_8\text{H}_8$  (150°) (236°-246°) (P. a. W.), retisterene [67°] (325°) (T. R. a. D.), carbonic acid, carbonic oxide, ethylene (S.), propylene (S.), heptane (97°) (T.), octane (S.), a valerylene (50°) (C.), cymenes (170°-178°) (K.), heptinene  $\text{C}_{11}\text{H}_{12}$  (101°) (R.), colophenone  $\text{C}_{11}\text{H}_{10}\text{O}$  (S.) (97°), a terpene (160°) (S.), abietic acid (K.), isobutyric and methyl-propyl-acetic acids (K.), hydrocarbons  $\text{C}_{11}\text{H}_{10}$  (190°-200°) (K.), and iso-butyric aldehyde (T.). Renard (*A. Ch.* [6] 1, 223) found among the products of distillation of colophony (rosin oil), pentane, amylene, hexane, hexylene, toluene, toluene tetrahydride, toluene hexahydride, xylene, xylene tetrahydride, xylene hexahydride, *m*-ethyl-propyl-benzene, terpenes, isobutyric aldehyde and acid, and valeric aldehyde and acid. Lwoff (*B.* 20, 1017) found, in resin oil, valeric, heptonic, ennoic, and hendecic acids. Resin oil is coloured violet by  $\text{H}_2\text{SO}_4$  of S.G. 1.53 (Holde, *C. C.* 1888, 952).

**Resin of *Pinus Laricio* (Poir).** [c. 100°]. V. sol. alcohol, ether, and oil of turpentine; insol. ligroin. Contains much methoxyl (Bamberger, *M.* 12, 411). Turned red by air, and finally brown. It contains a little free caffeic acid  $\text{C}_8\text{H}_7(\text{OH})\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$  [195°] and ferulic acid [4:3:1]  $\text{C}_8\text{H}_7(\text{OH})(\text{OMe})\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$  [169°]. 4 p.c. of caffeic and 1 p.c. of ferulic acid may be extracted by boiling with water. The resin also contains some vanillin  $\text{C}_8\text{H}_7(\text{OH})(\text{OMe})\cdot\text{CHO}$ . The resin yields pyrocatechin and protocathechuic acid on fusion with potash.

**Resin of *Picea vulgaris* (Link).** [c. 100°]. Contains methoxyl (Bamberger, *M.* 12, 456). Contains *p*-coumaric acid and vanillin. Potash-fusion gives protocathechuic and *p*-oxybenzoic acids.

**Resin of *Pinus sylvestris*** contains an acid  $\text{C}_{20}\text{H}_{30}\text{O}_4$  [143°], insol. water, v. sol. alcohol, ether, and  $\text{HOAc}$ .  $[\alpha]_D = -74^\circ$ . It yields the salts  $\text{C}_{20}\text{H}_{28}\text{AgO}_4$ ,  $(\text{C}_{20}\text{H}_{28}\text{O}_4)_2\text{Ba}2\text{aq}$ ,  $(\text{C}_{20}\text{H}_{28}\text{O}_4)_2\text{Ca}$ , and  $(\text{C}_{20}\text{H}_{28}\text{O}_4)_2\text{Cu}$ , and oily  $\text{C}_{20}\text{H}_{28}\text{EtO}_4$ , which on distillation forms oily  $\text{C}_{20}\text{H}_{28}\text{EtO}_4$ . Alcoholic  $\text{HCl}$  converts the acid into an isomeride [160°],  $[\alpha]_D = -93^\circ$  (Shkateloff, *J. R.* 20, 477).

**Resin from *Ficus rubiginosa*** contains 'sycoceryl acetate'  $\text{C}_{21}\text{H}_{38}\text{O}_2$  [121°] which on saponification gives acetic acid and sycoceryl alcohol  $\text{C}_{21}\text{H}_{38}\text{O}$  [114°] (De la Rue a. Müller, *Tr.* 1860, 43; Rennie a. Goyder, *C. J.* 61, 916).

**Formation.**—1. By potash-fusion from galbanum (Hlasiwetz a. Barth, *A.* 130, 354), *m*-iodo-phenol (Körner, *Bl.* [2] 7, 261), phenol-*p*-sulphonic acid (Glutz, *Bl.* [2] 8, 361), *p*-chloro-benzene sulphonic acid (Oppenheim a. Vogt, *A. Suppl.* 6, 376), from umbelliferone (Hlasiwetz a. Grabowski, *A.* 139, 99), from asafetida, from gum ammoniac, from sagapenum, from acaroid resin (Hlasiwetz, *A.* 130, 354; 138, 63; 139, 78), from *o*-, *m*-, and *p*-bromo-phenol (Fittig a. Mager, *B.* 8, 362), from *p*-chloro-phenol (Faust, *B.* 6, 1022), from *p*-iodo-phenol above 165° (Nölting a. Wrzesinsky, *B.* 8, 820), from phenol (Barth a. Schreder, *B.* 12, 420), and from benzene *m*- or *p*-disulphonic acid (Barth a. Senhofer, *B.* 8, 1483; Fahlberg, *Am.* 2, 195).—2. By dry distillation of brazilin (E. Kopp, *B.* 6, 446).—3. By the action of nitrous acid on *m*-amido-phenol (Bantlin, *B.* 11, 2101).

**Preparation.**—By fusing benzene *m*-disulphonic acid with NaOH (Mühlhäuser, *D. P. J.* 263, 154).

**Properties.**—Colourless trimetric tables (from water, alcohol, or ether); *a:b:c* = 912:1:1.059 (Calderon, *C. R.* 84, 779) or needles (from benzene). *V.* sol. water, alcohol, and ether, insol. chloroform and CS<sub>2</sub>. Acquires a reddish tint on exposure to air. Neutral to litmus. Has a sweet taste. FeCl<sub>3</sub> colours its aqueous solution dark violet. Its ammoniacal solution, exposed to the air, becomes rose-red and finally brown. The ammoniacal solution leaves on evaporation a dark-blue mass, which forms a blue solution, turned red by acids. Bleaching-powder gives a transient violet colour. A drop of a solution of NaOCl gives a violet colour, quickly changing to yellow, and on heating to dark-red or brown (Stark, *Ph.* [3] 21, 848; Boddé, *Ar. Ph.* [3] 27, 656). Resorcin reduces boiling ammoniacal AgNO<sub>3</sub> and boiling Fehling's solution. On heating resorcin with a few drops of nitro-benzene and conc. H<sub>2</sub>SO<sub>4</sub> a blue mass is got which, when poured into water and made alkaline, gives a solution with vermilion fluorescence. If resorcin is added to conc. H<sub>2</sub>SO<sub>4</sub> and a little NaNO<sub>2</sub>, and the mixture is heated to 100°, a product is got which, when mixed with water and rendered alkaline by NH<sub>3</sub>, imparts to fusel oil a crimson colour with vermilion fluorescence (Bindschedler, *M.* 5, 168). Resorcin fused with phthalic anhydride forms fluorescein, which dissolves in aqueous alkalis with strong green fluorescence (Baeyer, *A.* 183, 8). Resorcin heated with alcohol, beet-sugar, and HClAq gives a reddish-violet colour (Ihl, *Chem. Zeit.* 13, 264). A solution of resorcin (1 pt.) in absolute alcohol (2 pts.), mixed with an aldehyde and a few drops of conc. HClAq, gives, after standing for some hours and then pouring into water, a resinous or crystalline pp. (Michael a. Ryder, *Am.* 9, 134). A mixture of resorcin and furalaldehyde touched with a drop of HCl gives an indigo-blue substance, which dissolves with green colour in water, and is ppd. by HCl in blue flakes (Baeyer, *B.* 5, 25). On warming a liquid containing chloral or chloroform with resorcin and NaOH a yellowish-red colour with green fluorescence is got (Schwarz, *Fr.* 27, 668). Cupric sulphate and excess of ammonia form a deep-black liquid, which dyes wool black (Wagner, *D. P. J.* 220, 86).

**Titration.**—1. Bromine-water is run in until all the resorcin is converted into tribromo-resorcin, which is ppd.:  $C_6H_3(OH)_3 + 3Br_2 = C_6H_2Br_3(OH)_3 + 3HBr$ . The excess is determined by adding KI and titrating with hyposulphite (Degener, *J. pr.* [2] 20, 322).—2. Potash and potassium iodide are added to the solution, and then a neutral solution of bleaching-powder is run in. On adding HCl a pp. of tri-iodo-resorcin is formed, and the excess of iodine is titrated by hyposulphite (Degener).

**Reactions.**—1. Soda-fusion gives phloroglucin (65 p.c.), some pyrocatechin (3 p.c.), and tetra-oxy-diphenyl (1½ p.c.) (Barth a. Schreder, *B.* 12, 503).—2. Exhaustive chlorination in presence of I forms CCl<sub>4</sub> and CO<sub>2</sub> (Ruoff, *B.* 9, 1483).—3. ICl forms tri-iodo-resorcin (Michael a. Norton, *B.* 9, 1752).—4. An alkaline solution gives with KI a violet-red pp. of C<sub>6</sub>H<sub>2</sub>I<sub>3</sub>KO<sub>2</sub> (Messinger a. Vortmann, *B.* 22, 2320).—5. A solution of resorcin (10 g.) in water (100 c.c.) gives a purple colour with 5 c.c. of very dilute solutions of nitrates, to which a drop of 15 p.c. HClAq and 2 c.c. of H<sub>2</sub>SO<sub>4</sub> have been added (Lindo, *C. N.* 58, 176).—6. Resorcin (15 g.) dissolved in water (70 c.c.) and warmed with a mixture of (60 c.c. of) HBrAq (S.G. 1.47) and (20 c.c. of) HNO<sub>3</sub> (S.G. 1.39) gives C<sub>6</sub>H<sub>2</sub>BrN<sub>3</sub>O<sub>3</sub> as a lustrous violet mass, which forms a red solution in alcohol, changed by alkalis to a blue liquid (Brunner a. Krämer, *B.* 17, 1873; 21, 2481). It yields C<sub>6</sub>H<sub>2</sub>BrN<sub>3</sub>O<sub>3</sub> as an orange-red amorphous powder [120°], *v. sol.* hot alcohol. 7. Resorcin (15 g.) heated with water (60 g.), HNO<sub>3</sub> (20 c.c. of S.G. 1.39), and HCl (60 c.c. of S.G. 1.2) for half an hour on a water-bath forms a violet mass C<sub>6</sub>H<sub>2</sub>BrN<sub>3</sub>O<sub>3</sub>, insol. chloroform, sol. alcohol and ether. It yields yellowish-brown flocculent C<sub>6</sub>H<sub>2</sub>BrN<sub>3</sub>O<sub>3</sub> (Brunner, *B.* 21, 2479).—8. A blue colouring matter (laccoid) is got by heating resorcin (55 pts.) with NaNO<sub>2</sub> (18 pts.) at 130°, dissolving in NH<sub>4</sub>Ac and reppg. by HCl (Benedikt a. Julius, *M.* 5, 534).—9. Bromine in CS<sub>2</sub> forms C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>(OH)<sub>2</sub> [111°] (Zehenter, *M.* 8, 293).—10. With AlCl<sub>3</sub> it gives the compound (C<sub>6</sub>H<sub>2</sub>O<sub>2</sub>)Al<sub>2</sub>Cl<sub>3</sub>, which is *v. sol.* hot CS<sub>2</sub>, less sol. cold CS<sub>2</sub>; decomposed at once by water into resorcin, Al<sub>2</sub>O<sub>3</sub>, and HCl (Claus a. Merklin, *B.* 18, 2934).—11. Dry ammonia passed into a solution of resorcin in dry ether forms (C<sub>6</sub>H<sub>2</sub>O<sub>2</sub>)NH<sub>3</sub>, which separates as a liquid, solidifying as colourless deliquescent crystals, turning green and afterwards blue in the air (Malin, *A.* 138, 80).—12. H<sub>2</sub>O<sub>2</sub> and NH<sub>4</sub>Ac give, after acidification, a brown pp. ('laccoid') which forms an indigo blue solution in alkalis (Zulkowsky a. Peters, *M.* 11, 243; cf. Wurster, *B.* 20, 2934).—13. Ammonium carbonate solution at 125° forms (4,2,1)- and (6,2,1)-di-oxy-benzoic acid (Senhofer a. Brunner, *Sitz. W.* [2] 80, 504).—14. Ammoniacal CaCl<sub>2</sub> at 300° forms a brownish-red colouring matter [72°], insol. water and alkalis, sol. alcohol (Seyewitz, *C. R.* 109, 946).—15. Sulphur and NaOHAq form, on boiling, C<sub>6</sub>H<sub>2</sub>O<sub>2</sub>S<sub>2</sub>, a yellow powder, sol. alkalis, insol. water, and decomposing before fusion (Lange, *B.* 21, 263).—16. K<sub>2</sub>S<sub>2</sub>O<sub>8</sub>, acting on potassium resorcin forms C<sub>6</sub>H<sub>2</sub>(OH)(O.SO<sub>2</sub>K) and C<sub>6</sub>H<sub>2</sub>(O.SO<sub>2</sub>K)<sub>2</sub>. The latter salt is converted, by heating in the dry state at 160°, into a salt of resorcin disulphonic acid (Baumann, *B.* 11, 1911).—17. COCl<sub>2</sub> forms

$C_6H_4CO_2$ , a red amorphous substance, insol. water, v. sol. alcohol (Birnbbaum, *B.* 14, 1753).—18. An alcoholic solution of *potassium xanthate* forms  $C_6H_4(OH)_2CS_2H$ , crystallising in yellow needles [131°], sol. hot water (Lippmann a. Fleissner, *M.* 9, 296).—19. *Acetone dicarboxylic acid* and conc.  $H_2SO_4$  form (8) umbelliferone-acetic acid  $\begin{matrix} C(OH):CH(C_2O_2CO) \\ CH=CH.C.C(C_2H_5CO_2H) \end{matrix} > CH$  [202], crystallising in needles (containing aq), insol. ether (Michael, *J. pr.* [2] 37, 469).—20. *Benzene sulphonic chloride* added to a solution kept slightly alkaline forms  $C_6H_4(O_2SO_2C_2H_5)_2$ , crystallising from hot alcohol in needles [70°] (Georgesen, *B.* 24, 417).—21. *Hydrogen ammonium o-sulphobenzoic acid* forms  $C_{12}H_{12}NSO_4$  2aq as pale-yellow crystals, v. sol. water and alcohol. Its alkaline solutions are slightly fluorescent. Conc.  $HCl$  aq at 220° reconverts it into the parent substances (Fahlberg a. Barge, *B.* 22, 754). Resorcin (4 mols.) heated with o-sulphobenzoic acid (1 mol.) forms  $C_{12}H_{12}NSO_4$  4aq.—22. *Chloro-acetic acid* forms  $C_6H_4(OCH_2CO_2H)_2$  [194°], which yields a di-bromo-derivative (Gabriel, *B.* 12, 1640).—23.  $ClCO_2Et$  acting on  $C_6H_4(OK)_2$  forms  $C_6H_4(O_2CO_2Et)_2$ , a thick oil (300°) (M. Wallach, *Z.* 226, 84).—24. Dry *oxalic acid* (1 mol.) in a sealed tube at 200° forms 'resorcin-oxalein'  $C_{10}H_6O_4$ , a hygroscopic red powder, sol. alcohol and ether (Claus, *B.* 10, 1305; 14, 2503). At 100° it becomes  $C_{10}H_{12}O_4$ , which is less sol. alcohol. Dilute alkaline solutions are yellow, with dark-green fluorescence. Bromine gives  $C_{10}H_6Br_2O_4$ .  $HNO_3$  forms  $C_{10}H_6(NO_2)_2O_4$ .  $H_2SO_4$  yields  $C_{10}H_6(SO_3H)_2O_4$ .  $Ac_2O$  forms red  $C_{10}H_6Ac_2O_4$  and colourless  $C_{10}H_6Ac_4O_4$ .—25. Crystallised oxalic acid (1 mol.) heated with resorcin (2 mols.) at 120° yields two compounds  $C_{12}H_{10}O_4$ , one of which fluoresces green in alkaline solutions (Gukessian, *B.* 11, 1184). 26.  $HOAc$  and  $ZnCl_2$  at 145° form di-oxy-acetophenone. Resorcin (100 g.) boiled with  $HOAc$  (200 g.) and  $ZnCl_2$  (300 g.) for two hours forms 'acetfluorescein'  $C_{12}H_{10}O_4$  and 'resacetin'  $C_{16}H_{12}O_4$ . Resacetin crystallises by spontaneous evaporation of its ammoniacal solution in red needles. Its solution in  $KOH$  aq is red, but soon turns brown. It yields the salts  $B'HCl$  2aq and  $B'H_2SO_4$  (dried at 110°) and a triacetyl derivative  $C_{16}H_{10}Ac_3O_4$  [229°]. Acetfluorescein forms minute brownish-red crystals. Its dilute alkaline solutions exhibit green fluorescence (Nencki a. Sieber, *J. pr.* [2] 23, 540; Rasiński, *J. pr.* [2] 26, 59).—27. Resorcin (20 pts.) heated with *formic acid* (10 pts.) and  $ZnCl_2$  (20 pts.) for 30 minutes at 140° forms 'resaurin'  $C_{18}H_{14}O_6$  or  $(C_6H_5(OH)_2)_2C < \begin{smallmatrix} O \\ C_6H_5(OH) \end{smallmatrix}$ . Resaurin is a brick-red hygroscopic powder, forming a red solution in alkalis, sol. alcohol, insol. ether and acids (Nencki a. Schmid, *J. pr.* [2] 23, 547).—28. On heating with  $ZnCl_2$  and *acetacetic ether* or *citric acid* 'resocyanin' is formed (Wittenberg, *J. pr.* [2] 24, 125; 26, 74; Schmid, *J. pr.* [2] 26, 81). Resocyanin can be prepared by heating dry *citric acid* (60 g.) with resorcin (60 g.) and  $H_2SO_4$  (150 g.) for an hour at 180°. Resocyanin  $C_{18}H_{14}O_6$  [185°] is insol. cold water, sl. sol. ether, v. sol. alcohol. Its alkaline solutions are colourless with blue fluorescence. Its solutions are not

coloured by  $FeCl_3$ . It yields  $C_{18}H_{12}Br_2O_6$  [250°] and  $C_{18}H_{14}Ac_2O_6$  [150°]. Resocyanin yields resorcin when fused with potash. It may be reduced to a hydride  $C_{18}H_{20}O_6$  [259°] which yields  $C_{18}H_{18}Ac_2O_6$  [222°].  $NaOMe$  and  $MeI$  give  $C_{18}H_{18}Me_2O_6$  [159°].—29. A cold alcoholic solution of *sodium malonic ether* forms  $C_{18}H_{14}O_6$  [191°], which is v. sol. hot alcohol, insol. cold water. Its alkaline solutions are fluorescent. It splits up when heated above 191° into  $CO_2$  and methyl-umbelliferone (Michael, *Am.* 5, 434; *J. pr.* [2] 35, 455; 37, 469).—30. Resorcin (7 pts.) heated with *phthalic anhydride* at 200° forms *fluorescein* (vol. ii. p. 557).—31. Resorcin (2 mols.) heated with *phthalimide* (1 mol.) and  $H_2SO_4$  at 100° forms  $C_{20}H_{14}NSO_4$ , a light-yellow powder, insol. benzene and ether, v. sol. alcohol. It forms  $C_{20}H_{12}NaNSO_4$  7aq and  $C_{20}H_{14}AcNSO_4$ , a yellowish-green crystalline powder (Ostretzer, *M.* 11, 425).—32. *p-Benzoyl-benzoic acid* forms, on heating, di-oxy-tri-phenyl-carbinol carboxylic anhydride (v. vol. iii. p. 738).—33. *Maleic anhydride* forms, on heating, *maleic-fluorescein*  $\begin{matrix} CH:CH \\ CO-O \end{matrix} > C < \begin{matrix} C_6H_5(OH) \\ C_6H_5(OH) \end{matrix} > O$ , which exhibits deep green fluorescence in alkaline solution and gives crystalline  $C_{18}H_{12}Et_2O_4$  and  $C_{18}H_{14}Ac_2O_4$  [167°] (Burckhardt, *B.* 18, 2864).—34. *Succinic acid* (13 g.) heated with resorcin (20 g.) and  $H_2SO_4$  (40 g.) at 195° forms 'succinyl-fluorescein'  $C_{18}H_{12}O_6$  or  $\begin{matrix} CH_2:CH_2 \\ CO-O \end{matrix} > C < \begin{matrix} C_6H_5(OH) \\ C_6H_5(OH) \end{matrix} > O$ , which is crystalline (containing 3aq) and fluoresces in alkaline solution. It yields  $C_{18}H_{12}Br_2O_6$  (Nencki a. Sieber, *J. pr.* [2] 23, 153).—35. *Tartaric acid* (1 mol.) heated with resorcin (2 mols.) and  $H_2SO_4$  (1 p.c.) at 165° forms resorcin-tartreïn, a dark olive-green powder, which fluoresces in alkaline solution (Fraude, *B.* 14, 2558).—36.  $Na_2CO_3$  added to a solution of resorcin and *quinone* forms a deep-green solution changing through yellow to brownish-red on shaking with air (Wurster, *B.* 20, 2934).—37. Heated with *aniline* and  $CaCl_2$  it yields *m-oxy-di-phenylamine*. With *aniline* and  $ZnCl_2$  it yields *di-phenyl-m-phenylene-di-amine* (Calm, *B.* 16, 2786; cf. Merz a. Weith, *B.* 14, 2345).—38. *Aldehyde* in presence of weak acids forms  $C_{18}H_{14}O_6$  or  $CH_2:CH(O_2C_2H_5)_2$ , yellow crystals, insol. water and ether, sol. alcohol. At 120° this body is converted into brown crystalline  $C_{20}H_{16}O_6$ . By heating the compound  $C_{18}H_{14}O_6$  with zinc-dust in a current of hydrogen at 300°, resorcin is produced.  $Ac_2O$  at 140° gives  $C_{18}H_{14}Ac_2O_6$  [282°] (Causse, *Bl.* [2] 47, 89; *J. Ph.* [5] 13, 354).—39. *Chloral hydrate* in aqueous solution containing  $NaHSO_4$  forms silky needles of  $C_{18}H_{12}O_6$ , insol. water and benzene, sol. ether and alcohol. Its alkaline solutions are fluorescent. It yields a diacetyl derivative [252°] (Causse, *Bl.* [3] 8, 861). Resorcin and *glyoxylic acid* yield the same  $C_{18}H_{12}O_6$ . By boiling chloral hydrate (5 pts.) with resorcin (10 pts.) and water (40 pts.) there is formed  $C_{18}H_{14}O_6$  crystallising from dilute alcohol in yellowish needles, and yielding  $C_{18}H_{14}Ac_2O_6$  [150°] and  $C_{18}H_{12}Br_2O_6$  [165°] (Michael a. Comey, *Am.* 5, 350).—40. *Benzoic aldehyde*, alcohol, and a little  $HCl$  give  $C_{20}H_{16}O_6$  2aq [above 330°], a colourless resin, insol. water, v. e. sol. alcohol. Its alkaline solution absorbs oxygen from the air.  $Ac_2O$  and  $NaOAc$  form  $C_{20}H_{16}Ac_2O_6$ .  $HCl$

converts it into the isomeric  $C_{22}H_{20}O_4$ , aq. crystallising from alcohol in dimetric tables, reduced by sodium-amalgam to  $C_{22}H_{22}O_4$ , crystallising from alcohol in prisms, and converted by  $Ac_2O$  and  $NaOAc$  into  $C_{22}H_{22}Ac_2O_4$ , crystallising from xylene in prisms (Michael, *Am.* 5, 840).—41.  $CH_3.CCl_3$  and caustic soda form  $CH_3.C(O.C_2H_5.OH)_2$ , [159°], v. sol. alcohol, sl. sol. hot water (Heiber, *B.* 24, 3684).—42. *Camphor* forms the compounds  $C_{22}H_{20}O_2(C_{10}H_{16}O)$  [29°],  $[a]_D = 22.5^\circ$ , crystallising in hygroscopic rectangular plates, and  $C_{22}H_{20}O_2(C_{10}H_{16}O)_2$ , a syrupy liquid, S.G. 1.037;  $[a]_D = 25.9^\circ$  (Léger, *C. R.* 111, 110).—43. *Phenyl-hydrazine* (2 mols.) rubbed with powdered resorcin (1 mol.) forms  $C_{22}H_{20}O_2.2N_2H_4Ph$ , crystallising in unstable satiny needles [76°], v. sol. benzene alcohol, and ether. It is decomposed by water and alkalis (Baeyer a. Kochendörfer, *B.* 22, 2195).—44. *Quinone* (1 mol.) added to a solution of resorcin (1 mol.) in hot benzene forms  $C_{12}H_8O_4$  [c. 90°] crystallising in dark-red needles with green reflex, m. sol. water (Nietzki, *A.* 215, 136).—45. *Cyanic acid* passed into an ethereal solution of resorcin forms  $C_8H_8N_2O_4$ , [120°], sl. sol. ether, m. sol. hot water (Traube, *B.* 22, 1579).—46. *Phenyl cyanate* forms at 100°  $C_8H_8(O.CO.NHPh)_2$ , [164°] (Snape, *C. J.* 47, 772).—47. *Urea* (2 pts.) in a current of  $CO_2$  at 250° forms  $C_{20}H_{20}N_4O_4$ , aq., an olive-brown amorphous powder, melting above 360°, v. sl. sol. hot  $HOAc$ , sl. alkalis (Birnbbaum, *B.* 13, 1619).—48. Heated with aqueous  $KHCO_3$  or ammonium carbonate it yields di-oxy-benzoic acid.—49. Resorcin (1 pt.) mixed with acetone (2 pts.) and fuming  $HClAq$  (1 pt.) forms  $C_{15}H_{10}O_4$  or  $CMex(O.C_2H_5.OH)_2$ , which crystallises in small prisms [213°], insol. water and ether, sol.  $KOHAq$  and  $Na_2CO_3Aq$ . It is decomposed by heat into acetone and resorcin. It forms a crystalline hydrate  $C_{15}H_{10}O_4.aq.$   $Ac_2O$  yields  $C_{15}H_{10}Ac_2O_4$ , [126°] while  $BzCl$  gives  $C_{15}H_{10}.Bz_2O_4$ , [115°] (Causse, *Bz.* [3] 7, 563).—50. Resorcin (20 g.) heated with  $K_2CS_2$  under pressure at 100° forms  $C_8H_8S_2O_4$ , [150°–155°], sl. sol.  $CS_2$ , converted by potash-fusion into resorcin and (4,2,1)-di-oxy-benzoic acid [205°] (Pribram a. Glücksmann, *M.* 13, 626).

*Mono-methyl ether*  $C_6H_4(OH)(OMe)$ . (244°). V.D. ( $H=1$ ) 62.2 (obs.). Formed by heating resorcin (1 mol.) with  $KOH$  (1 mol.) and  $KMeSO_4$  at 160° (Habermann, *B.* 10, 868). Formed also from resorcin,  $NaOMe$ , and  $MeI$  (Tiemann, *B.* 13, 2362; 14, 2019). Prepared by heating resorcin with  $MeOH$  and  $KHSO_4$  for 10 hours at 180° (Wallach, *B.* 16, 151). Liquid, sol. hot water, alcohol, ether, benzene, and  $NaOHAq$ . Slightly volatile with steam.  $FeCl_3$  colours its solution violet. Acetic anhydride forms  $C_6H_4(OAc)(OMe)$  (255°).  $KOH$  and  $K_2S_2O_8$  form  $C_6H_4(OMe)(SO_3K)$ , crystallising in plates, sol. water and hot alcohol.

*Di-methyl ether*  $C_6H_4(OMe)_2$ . (215°) (R. Schiff, *B.* 19, 562); (224°) (Stohmann). V.D. 68.8 (obs.). S.V. 157.13. S.G.  $\approx 1.075$ . H.F.p. 74.034 [ $C_{10}H_8=94,000$ ;  $H_{22}O=69,000$ ] (Stohmann, *J. pr.* [2] 85, 27). S.V. 157.1. Prepared by heating resorcin (1 pt.) with  $MeOH$ ,  $KOH$  (1.5 pts.), and  $MeI$  (3 pts.) for 6 hours at 250° (Oechsner de Coninck, *Bz.* [2] 34, 149). Oil, v. sol. alcohol and ether. Volatile with steam. Not coloured by  $FeCl_3$ .

*Methyl ethyl ether*  $C_6H_4(OMe)(OEt)$ . (216°). Formed from  $C_6H_4(OH)(OMe)$ ,  $KOH$ , and  $K_2SO_4$  at 165°; the product being distilled with steam (Spitz, *M.* 5, 488). Liquid.

*Methyl propyl ether*  $C_6H_4(OMe)(OPr)$ . (226°). Colourless liquid.

*Methyl isobutyl ether*  $C_6H_4(OMe)(OCH_2Pr)$ . (234°). Liquid.

*Methyl isoamyl ether*  $C_6H_4(OMe)(OC_4H_9)$ . (236°). Liquid.

*Mono-ethyl ether*  $C_6H_4(OH)(OEt)$ . Liquid.  $HNO_3$  saturated with nitrous acid added to its ethereal solution at 0° forms  $C_6H_4(NO_2)(OH)(OEt)$  and two colouring matters:  $C_{20}H_{12}N_2O_4$ , [230°] crystallising in red needles, insol. water, sl. sol. boiling alcohol, forming a purple solution in  $H_2SO_4$ ; and  $C_{11}H_7N_2O_4$ , [223°] crystallising in orange-red needles, forming a bluish-violet solution in  $H_2SO_4$  (Weselsky a. Benedikt, *M.* 1, 891).

*Di-ethyl ether*  $C_6H_4(OEt)_2$ . [12.4°]. (229°) (Pukall, *B.* 20, 1140); (235°) (Herzig a. Zeisel, *M.* 11, 300). Formed from resorcin,  $KOH$ , and  $EtI$ . Colourless prisms, volatile with steam. On adding one drop of  $KNO_3$  solution followed by  $HClAq$  to its solution in  $HOAc$ , an intense emerald green colour is produced. Yields two di-bromo-derivatives [101°] and [77°]. Converted by dissolving in  $HOAc$ , adding  $NaNO_2$ , and passing in  $HCl$  into  $C_6H_4(NO)(OEt)$ , [123°] and  $C_6H_4(NO)(OH)(OEt)$ , whence  $BzCl$  forms yellow crystals of  $C_6H_4(NO)(OEt)(OBz)$  [155°] (Kraus, *M.* 12, 374).

*Hexa-chloro-di-vinyl ether*  $C_6H_2(OC_2Cl_2)_2$ . [54°]. Formed by heating  $C_6H_4(OAc)_2$  with  $PCl_5$  at 100° (Michael, *Am.* 9, 210). Long prisms, insol. hot water.

*Di-propyl ether*  $C_6H_4(OPr)_2$ . (251°). V.D. 7.02 (obs.). Liquid, m. sol. hot water, sol. alcohol, ether, and ligroin (Kariof, *M.* 1, 258; *B.* 13, 1677). Br forms  $C_6H_4Br(OPr)_2$ , [70°].

*Mono-benzyl ether*  $C_6H_4(OH)(OC_6H_5)$ . Formed from resorcin,  $KOH$ , alcohol, and benzyl bromide (Schiff a. Pellizzari, *A.* 221, 376; *G.* 13, 504).

*Di-benzyl ether*  $C_6H_4(OC_6H_5)_2$ . [76°]. Glittering tables (from alcohol).

*Tetra-nitro-di-phenyl ether*  $C_6H_4(O.C_6H_4(NO_2))_2$ . [184°]. Formed from resorcin,  $NaOEt$ , and (1,2,4)-chloro-di-nitro-benzene in alcohol (Nietzki a. Schündelen, *B.* 24, 3586). Colourless plates. Converted by  $HNO_3$  into a penta-nitro-derivative [68°], and by  $H_2SO_4$  and  $HNO_3$  into the hexa-nitro-di-phenyl ether [220°].

*Di-acetyl derivative*  $C_6H_4(OAc)_2$ . (273°) (Nencki, *J. pr.* [2] 23, 147); (278° i.V.) (Typke, *B.* 16, 552). Formed from resorcin and  $AcCl$  (Malin, *A.* 138, 79). Oil.

*Di-benzoyl derivative*  $C_6H_4(OBz)_2$ . [117°]. H.F. 124.598 (Stohmann, *J. pr.* [2] 36, 10). From resorcin (5 g.), benzoic acid (11 g.) and  $POCl_3$  (13 g.), the latter being added slowly (Rasiński, *J. pr.* [2] 26, 64). Formed also by shaking resorcin with  $BzCl$  and  $NaOHAq$  (Hinsberg, *A.* 254, 254). Plates (from ether).

*Anhydride*  $C_{12}H_{10}O_2$  i.e.  $O(C_6H_4.OH)_2$ . *Resorcinyl oxide*. *Resorcin ether*. Formed by heating resorcin with  $NaOH$  and  $CO_2$  (Böttger, *B.* 9, 182), with  $Na$  and  $CO_2$  (Barth, *B.* 9, 309),

with  $\text{HClAq}$  under pressure (Barth a. Weider, *B.* 10, 1464), or with  $\text{H}_2\text{SO}_4$  (Barth, *A.* 164, 122; Kopp, *B.* 6, 447; Annaheim, *B.* 10, 976). Formed also by heating resorcin at  $195^\circ$  with the disulphonic acid of resorcin or of phenanthrene (Hazura a. Julius, *M.* 5, 191). Brownish-red amorphous powder, acquiring by pressure a green metallic lustre. Nearly insol. water, v. sl. sol. cold alcohol and ether.  $\text{KOH aq}$  forms a dark red solution with green fluorescence. Potash-fusion reconverts it into resorcin. Oxidised by nitric acid to isophthalic acid. Yields  $\text{C}_{12}\text{H}_8\text{Ac}_2\text{O}_8$ , which forms a reddish-violet solution in alkalis, and  $\text{C}_{12}\text{H}_8\text{Br}_2\text{O}_8$ .

**Anhydride**  $\text{C}_{12}\text{H}_8\text{O}_8$ . Formed, together with  $\text{C}_{12}\text{H}_{10}\text{O}_8$ , by heating resorcin with  $\text{HClAq}$  at  $180^\circ$ . Brick-red powder, v. sol. alcohol and ether. Its alkaline solution is brownish-yellow with violet-blue fluorescence. Yields  $\text{C}_{12}\text{H}_{10}\text{Ac}_2\text{O}_8$  and  $\text{C}_{12}\text{H}_{12}\text{Br}_2\text{O}_8$ . Oxidised by nitric acid to isophthalic acid.

**Resazurin**  $\text{C}_{12}\text{H}_8\text{NO}_4$  (B. a. K.), or  $\text{C}_{12}\text{H}_8\text{NO}_4$  (Nietzki, *B.* 22, 3021; 24, 3366). **Diazoresorcin.** **Azoresorcin.** **Resazoin.** Formed by the action of nitrous acid on an ethereal solution of resorcin (Weselsky, *B.* 4, 613; *M.* 1, 889; 5, 607). Formed also by the action of  $\text{MnO}_2$  and  $\text{H}_2\text{SO}_4$  on an alcoholic solution of resorcin and nitroso-resorcin. Prepared by adding fuming  $\text{HNO}_3$  (6 c.c.) to resorcin (10 g.) dissolved in ether (500 c.c.) at  $-7^\circ$ . Dark-red prisms with green reflex. Insol. water and ether, v. sl. sol. cold alcohol and  $\text{HOAc}$ . Its alkaline solutions are bluish-violet. Conc.  $\text{H}_2\text{SO}_4$  forms a red solution.  $\text{HCl}$  forms a crystalline hydrochloride. Yields  $\text{Ba}(\text{C}_{12}\text{H}_8\text{NO}_4)_2$  crystallising in brown needles, and a sodium salt, which forms greenish needles, v. sol. water, sl. sol.  $\text{NaOHAq}$ , fluorescing brick red in dilute alcoholic solution. Resazurin forms  $\text{C}_{12}\text{H}_8\text{Br}_2\text{NO}_4$  on bromination.

**Reactions.**—1.  $\text{AcCl}$  in a sealed tube at  $100^\circ$  forms  $\text{C}_{12}\text{H}_8\text{Cl}_2\text{NO}_4$  (?) crystallising from  $\text{HOAc}$  in golden plates and amorphous  $\text{C}_{12}\text{H}_8\text{Cl}_2\text{N}_2\text{O}_6$  (?) (Weselsky, *A.* 162, 288; Brunner a. Krämer, *B.* 17, 1854).—2. Conc.  $\text{H}_2\text{SO}_4$  at  $210^\circ$  and conc.  $\text{HClAq}$  at  $100^\circ$  form resorufin.—3. On heating with *tin* and conc.  $\text{HClAq}$  an emerald-green solution is got, from which on cooling 'hydrodiazoresorufin hydrochloride' separates as colourless leaflets or needles, which, when exposed to air, acquire a coppery lustre, and when heated in a current of air produce resorufin. Hydrodiazoresorufin is dioxypheinoxazine, the formula being  $\text{C}_6\text{H}_4(\text{OH}) < \overset{\text{O}}{\text{N}} > \text{C}_6\text{H}_3\text{OH}$  (Nietzki, *B.* 22, 3020).

4. Hot conc.  $\text{HNO}_3$  forms 'tetrazoresorcin nitrate'  $\text{C}_{12}\text{H}_8\text{N}_4\text{O}_{11}$  (?), crystallising in lustrous garnet-red needles, sol. water, alcohol, and ether with indigo-blue colour. According to Brunner a. Krämer (*B.* 17, 1864; 18, 587) these crystals are tri-nitro-resazurin  $\text{C}_{12}\text{H}_8(\text{NO}_2)_3\text{NO}_4$ . By heating them with conc.  $\text{HNO}_3$  Weselsky obtained 'tetrazoresorufin nitrate'  $\text{C}_{12}\text{H}_8\text{N}_4\text{O}_{11}$  (?), crystallising from  $\text{NHO}$ , in dark-red needles, and from wet ether in purple needles (containing 11 aq). *Tin* and  $\text{HClAq}$  acting upon either of these bodies form a red body, probably tri-amido-resorufin hydrochloride, and a colourless body, probably tri-amido-di-oxy-pheinoxazine. By passing air through an ammoniacal solution of the colourless body there are formed lustrous green crystals of 'hydroimidotetrazoresorufin'.

$\text{C}_{12}\text{H}_8\text{N}_4\text{O}_{11}$  aq (W.) or  $\text{C}_{12}\text{H}_8(\text{NH}_2)_3\text{NO}_4$  (B.) (possibly tri-amido-resorufin).—5. **Bromine** added to its solution in  $\text{NaOHAq}$  forms  $(\text{C}_{12}\text{H}_8\text{Br}_2\text{NO}_4)\text{HBr}$  as a lustrous green mass, forming a blue alcoholic solution with red fluorescence (Brunner a. Krämer, *B.* 17, 1862). Nietzki obtained  $\text{C}_{12}\text{H}_8\text{Br}_2\text{NO}_4$ , which gave  $\text{C}_{12}\text{H}_8\text{NaBr}_2\text{NO}_4$ , 2aq, crystallising from dilute alcohol in lustrous green prisms.—6. Oxidised in  $\text{KOH}$  solution by  $\text{H}_2\text{O}_2$  to oxyresazurin  $\text{C}_{12}\text{H}_{12}\text{N}_2\text{O}_8$  (?), which forms almost colourless crystals giving a reddish-yellow solution in alkalis. This compound is also formed by alkaline  $\text{KMnO}_4$ . It is reduced by zinc-dust to  $\text{C}_{12}\text{H}_{14}\text{N}_2\text{O}_8$  (?), crystallising in colourless needles (Ehrlich, *M.* 8, 425).

**Acetyl derivative**  $\text{C}_{12}\text{H}_8\text{AcNO}_4$ . [222°]. Formed by heating the sodium compound with  $\text{NaOAc}$  and  $\text{Ac}_2\text{O}$  at  $100^\circ$  (Nietzki, *B.* 22, 3024). Ruby-red needles.

**Ethyl ether**  $\text{C}_{12}\text{H}_8\text{EtNO}_4$ . [215°]. Formed from the Ag salt, alcohol, and  $\text{EtI}$ . Dark-red needles. According to Weselsky the formula of the ether [202°] got from resazurin, alcohol, and  $\text{HCl}$  at  $100^\circ$  is  $\text{C}_{12}\text{H}_8\text{Et}_2\text{N}_2\text{O}_8$ .

**Resorufin**  $\text{C}_{12}\text{H}_8\text{NO}_3$ , i.e.  $\text{CO} \cdot \text{CH} : \text{C} \cdot \text{O} \cdot \text{CH} : \text{C} \cdot \text{OH}$   
 $\text{CH} : \text{CH} : \text{C} \cdot \text{N} : \text{C} \cdot \text{CH} : \text{CH}$ . **Azoresorufin.** **Diazoresorufin.**

**Formation.**—1. By heating resazurin with conc.  $\text{H}_2\text{SO}_4$  at  $210^\circ$ .—2. By heating resorcin with a solution of nitrous acid in  $\text{H}_2\text{SO}_4$  (Brunner a. Krämer, *B.* 17, 1847).—3. By warming nitroso-resorcin with resorcin and  $\text{H}_2\text{SO}_4$  (Fevre, *Bl.* [2] 39, 593).—4. By heating resorcin with nitrobenzene and  $\text{H}_2\text{SO}_4$  at  $170^\circ$ .—5. By the action of zinc-dust on an ammoniacal solution of resazurin (Weselsky a. Benedikt, *M.* 5, 608).—6. By boiling resazurin (1 pt.) with  $\text{FeCl}_3$  (2 pts.) and fuming  $\text{HClAq}$  (10 pts.) and ppg. with water (W. a. B.).—7. By action of nitroso-phenol on resorcin or of nitroso-resorcin on phenol in presence of  $\text{H}_2\text{SO}_4$  (Nietzki, *B.* 22, 3020; 23, 718).—8. By adding  $\text{MnO}_2$  to a solution of p-amido-phenol and resorcin in conc.  $\text{H}_2\text{SO}_4$ .

**Properties.**—Small dark-red grains (from dilute  $\text{HClAq}$ ), insol. water and ether, sl. sol. alcohol. Forms a bluish-violet solution in  $\text{H}_2\text{SO}_4$ . Alkalis form a crimson solution with scarlet fluorescence.

**Reactions.**—1. Reduced by *tin* and  $\text{HClAq}$  or by *zinc* and  $\text{HClAq}$  to dioxy-pheinoxazine  $\text{C}_{12}\text{H}_8\text{NO}_2$ , crystallising in nearly colourless needles, which soon become green in the air, and yielding  $\text{C}_{12}\text{H}_8\text{AcNO}_2$  [216°] crystallising in colourless needles, sl. sol. hot alcohol.—2. **Bromine** added to the alkaline solution yields the sodium salt  $\text{C}_{12}\text{H}_8\text{Br}_2\text{NO}_2 \cdot \text{Na} 2\text{aq}$ , crystallising in lustrous green needles.—3. **Nitric acid** (S.G. 1.37) forms a body crystallising in green needles, forming a purple solution in water, alcohol, and ether. This body is probably tri-nitro-resorufin. 4. Fuming  $\text{HCl}$  at  $100^\circ$  forms 'azoresorufyl chloride'  $\text{C}_{12}\text{H}_8\text{Cl}_2\text{N}_2\text{O}_3$  (?) crystallising in red plates, sol. ether (Brunner a. Krämer, *B.* 17, 1857). Its alkaline solution exhibits red fluorescence.

**Acetyl derivative**  $\text{C}_{12}\text{H}_8\text{AcNO}_3$ . [228°]. Formed by heating resorufin with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$ . Orange scales, v. sol. acetone, sl. sol. alcohol and ether.

*Ethyl ether*  $C_{12}H_{14}EtNO_3$ . [225°]. Orange-red needles (Nietzki).

**RESORCIN-AZO-** v. AZO-COMPOUNDS and DISAZO-COMPOUNDS.

**RESORCIN-BENZEIN** v. TETRA-OXY-TRIPHENYL-CARBINOL.

**RESORCIN CARBOXYLIC ACID** v. DI-OXY-BENZOIC ACID.

**Resorcin (a)-dicarboxylic acid**  
 $C_6H_4(OH)_2(CO_2H)_2$ . [276°]. Formed, together with di-oxy-benzoic acid, by heating resorcin (1 pt.) with ammonium carbonate (4 pts.) and water (5 pts.) in a sealed tube (Senhofer a. Brunner, *Bn.* 2, 1266). Minute tables (from water), v. sl. sol. hot water.  $FeCl_3$  colours its aqueous solution red. —KIA"aq: needles. —KA"3aq: needles, v. e. sol. water. —BA"5aq: needles. —CuA"5aq. —AgA": amorphous pp.

**Resorcin (8)-dicarboxylic acid**  
 $C_6H_4(OH)_2(CO_2H)_8$ . [250°]. Formed by heating (1,8,5)-di-oxy-benzoic acid with ammonium carbonate and water (S. a. B.). Four-sided prisms (containing aq), sl. sol. cold water.  $FeCl_3$  colours its solution violet. —K<sub>2</sub>A". —Ba(HA")<sub>2</sub>7aq. —BA"4aq: needles. —Ba<sub>2</sub>C<sub>6</sub>H<sub>3</sub>O<sub>2</sub>2aq (dried at 160°). —PbC<sub>6</sub>H<sub>3</sub>O<sub>2</sub>1aq. —CuA"3aq.

**Resorcin dicarboxylic acid**  
 $C_6H_4(OH)_2(CO_2H)_2$  [4:2:5:1] (?). [192°]. Formed by oxidising the corresponding aldehyde [127°] (Tiemann a. Lewy, *B.* 10, 2212). Slender needles.

**Diresorcin dicarboxylic acid** v. TETRA-OXY-DIPHENYL DICARBOXYLIC ACID.

**RESORCIN ALDEHYDE** v. DI-OXY-BENZOIC ALDEHYDE.

**Resorcin dicarboxylic aldehyde** v. DI-OXY-ISOPHTHALIC ALDEHYDE.

**RESORCIN-INDOPHANE**  $C_{12}H_8N_2O_8$ . Ppd., as K salt, by warming potassium tri-nitroresorcin with aqueous KCy (Schreder, *A.* 163, 297). Small lustrous needles, forming a bluish-violet aqueous solution. —Na<sub>2</sub>C<sub>6</sub>H<sub>3</sub>N<sub>2</sub>O<sub>8</sub>aq. —K<sub>2</sub>C<sub>6</sub>H<sub>3</sub>N<sub>2</sub>O<sub>8</sub>aq: dark-brown lustrous crystals, exploding when heated. —BaC<sub>6</sub>H<sub>3</sub>N<sub>2</sub>O<sub>8</sub>aq.

**DIRESORCIN-PHTHALEIN**  $C_{20}H_{12}O_8$  5aq (Link, *B.* 13, 1654) or  $C_{20}H_{12}O_8$  (Benedikt a. Julius, *M.* 5, 182). [245°]. Formed by heating diresorcin (tetra-oxy-diphenyl) with phthalic anhydride and SnCl<sub>4</sub> or H<sub>2</sub>SO<sub>4</sub> at 115°. Silvery plates or needles, forming an indigo-blue solution in alkalis. Converted by heating with zinc-dust and caustic soda into diresorcin-phthalin  $C_{22}H_{10}O_8$  8aq (L.) or  $C_{22}H_{10}O_8$  2aq (B. a. J.), crystallising from water in colourless plates [238°], forming a colourless solution in alkalis.

**RESORCIN SULPHONIC ACID**

$C_6H_3(OH)_2(SO_3H)$ . Formed by potash-fusion from the disulphonic acid (H. Fischer, *M.* 2, 337). —KA"2aq: crystals.

**Resorcin disulphonic acid**  $C_6H_3(OH)_2(SO_3H)_2$ . Prepared by sulphonation of resorcin (Piccard a. Humbert, *B.* 9, 1479; Tedeschi, *B.* 12, 1267). Deliquescent needles (containing 2aq), sol. water and alcohol, insol. ether.  $FeCl_3$  gives a red colour. Gives phloroglucin on fusion with

potash. Bromine forms tri-bromo-resorcin even in the cold. —KA"aq: needles. —KA"4aq: deliquescent needles. —NaA"aq. —BA"3aq. —BA"8aq. —Ba<sub>2</sub>C<sub>6</sub>H<sub>3</sub>S<sub>2</sub>O<sub>8</sub> 4aq. —CuA"10aq: triclinic crystals. —Ba<sub>2</sub>C<sub>6</sub>H<sub>3</sub>S<sub>2</sub>O<sub>8</sub> 5aq: crystals. —Pb<sub>2</sub>C<sub>6</sub>H<sub>3</sub>S<sub>2</sub>O<sub>8</sub> 4aq.

**Resorcin disulphonic acid**  
 $C_6H_3(OH)_2(SO_3H)_2$ . Formed from di-amido-benzene disulphonic acid by the diazo-reaction (Limpricht, *B.* 8, 290). Long four-sided needles. BA"2aq: crystalline pp., got by adding alcohol to its aqueous solution.

**Resorcin trisulphonic acid**  $C_6H_3(OH)_2(SO_3H)_3$ . Formed by heating the disulphonic acid with fuming H<sub>2</sub>SO<sub>4</sub> at 200° (Piccard a. Humbert, *B.* 10, 182). In neutral solution it gives a violet colour with  $FeCl_3$ . —Ba<sub>3</sub>A"3aq. Insol. water and HClAq.

**References.**—IODO-, NITRO-, and NITROSO-RESORCIN SULPHONIC ACID.

**RESORCYLIC ACID** v. DI-OXY-BENZOIC ACID.

**RESORCYLIC ALDEHYDE** v. DI-OXY-BENZOIC ALDEHYDE.

**Resorecylic dialdehyde** v. DI-OXY-ISOPHTHALIC ALDEHYDE.

**RETENE**  $C_{18}H_{18}$  i.e.  $CH_3C_6H_4[1:2]$ . Mol. w. 234. [98.5°]. (394°) (Schweizer, *A.* 264, 195). V.D. 8.3 (calc. 8.1) (Knecht, *B.* 10, 2074). S. (95 p.c. alcohol) 3 in the cold; 69 at 78°. S.G. (solid) 1.13 at 16°. I.C.v. 2,323,600. H.C.p. 2,326,100. H.F. —13,100 (Berthelot a. Vieille, *A. Ch.* [6] 10, 447). Occurs in scales in fossil pine-stems, accompanying fichtelite in peat bogs, and is a product of the distillation of wood (Fritsche, *J. pr.* 75, 281; Fehling, *A.* 106, 388; Wahlforss, *Z.* [2] 5, 73; Krauss, *A.* 106, 391; Ekstrand, *Bl.* [2] 24, 53; *A.* 185, 75; Bamberger a. Hooker, *A.* 229, 115). Produced by passing acetylene through a red-hot tube (Berthelot, *J.* 1866, 516). White plates, sol. alcohol, v. sol. hot HOAc, ether, and CS<sub>2</sub>. Not attacked by potash-fusion or by alkaline KMnO<sub>4</sub>. Dissolved by fuming HNO<sub>3</sub>. It is not attacked by sodium-amalgam or HIAq at 200°.

**Reactions.**—1. Absorbs chlorine, forming  $C_{18}H_{16}Cl_2$ , which splits up on heating into HCl and chloro-retene  $C_{18}H_{17}Cl$ , a crystalline body. —2. Bromine and water form di-bromo-retene  $C_{18}H_{16}Br_2$  [180°] crystallising from CS<sub>2</sub> in colourless tables. Excess of Br at 100° forms viscid  $C_{18}H_{14}Br_4$  and crystalline  $C_{18}H_{14}Br_4$  [212°]. —3. Oxidised by chromic acid mixture to retenequinone, phthalic acid, and HOAc. CrO<sub>3</sub> in HOAc forms retenequinone, retenic acid  $C_{18}H_{12}O_2$ , and an acid  $C_{18}H_{10}O_2$  crystallising from hot alcohol in plates [139°], forming NaA' and BA'2, both crystallising in plates.

**Compound with picric acid**  
 $C_{18}H_{14}C_6H_2(NO_3)_3OH$ . [124°]. S. (95 p.c. alcohol) 2.3 at 10°; 20 at 78°. Orange-yellow needles (from alcohol). Decomposed by water. Crystallises as  $(C_{18}H_{14})(C_6H_2)C_6H_2N_3O_7$  from benzene.

**Compound with di-nitro-anthraquinone.** Dark orange-red needles (from HOAc).

**Tetra-hydride**  $C_{18}H_{22}$ . (280° at 50 mm.). Formed by adding Na to a solution of retene in isoamyl alcohol (Bamberger a. Lodler, *B.* 20, 3076). Pale-yellow liquid.

**Dodeca-hydrate**  $C_{18}H_{36}$ . (336° uncor.). Formed by heating retene with HI and P at 260° (Liebermann a. Spiegel, *B.* 22, 780). Colourless oil with bluish fluorescence. Yields no retenequinone when oxidised by  $HNO_3$ .

**Perhydrate**  $C_{18}H_{36}$ . [48°]. (335° i.v.) at 719 mm. V.D. 8.69 (calc. 8.58). This is probably the constitution of fichtelite (Bamberger a. Strasser, *B.* 22, 3361; Spiegel, *B.* 22, 3369; cf. vol. ii. p. 548). By heating with iodine it is converted into  $C_{18}H_{16}$  (346° cor.) at 714 mm.

**RETENE-FLUORENE** v. METHYL-ISOPROPYL-FLUORENE.

**RETENE-GLYCOLLIC ACID**  $C_{18}H_{18}O_3$  i.e.  $C_{18}H_{16}:C(OH).CO_2H$ . Formed by boiling retenequinone with  $NaOH$ aq (Bamberger a. Hooker, *A.* 229, 132). White crystals, sl. sol. hot water. — $AgA'$ : flocculent pp., sl. sol. hot water.

**RETENE KETONE** v. METHYL-ISOPROPYL-DIPHENYLENE KETONE.

**RETENEQUINONE**  $C_{18}H_{16}O_2$  i.e.  $CO_2C_6H_4.CO_2H$ . *Retistenequinone*. *Dioxy-retistene*. [192°]. S. (95 p.c. alcohol) 15 at 0°; 2.2 at 78°. Formed by oxidising retene with  $CrO_3$  in  $HOAc$  (Wahlforss, *Z.* [2] 5, 73; Ekstrand, *A.* 185, 75; Bamberger a. Hooker, *B.* 18, 1024; *A.* 229, 117). Orange-red prisms, v. sl. sol. cold alcohol and ether, sl. sol. aniline and  $HOAc$ , sol. benzene and chloroform. Not attacked by  $Cl$  in the cold. Not affected by hot  $HNO_3$ . Conc.  $H_2SO_4$  forms a green solution. Alcoholic potash imparts to its alcoholic solution a claret colour which disappears on shaking with air, but reappears on warming in absence of air.

**Reactions**.—1. Bromine forms  $C_{18}H_{16}Br_2O_2$  [252°], crystallising from  $HOAc$  in orange prisms. 2. Cold  $NaOHAq$  does not dissolve it, but on boiling converts it into retene-glycollic acid.—3. On distillation with *baryta* it yields retene-ketone and oily  $C_{18}H_{16}$  (215–220°).—4. Distillation with *zinc-dust* forms retene.—5.  $H$  and  $P$  reduce it to retene.—6. In boiling alcoholic solution it is reduced by sodium-amalgam to retene diphenic acid  $C_{18}H_{16}(CO_2H)_2$ , an unstable resin yielding  $AgA''$ .—7.  $KMnO_4$  forms oxy isopropyl-diphenylene ketone carboxylic acid.—8. *Phenyl-ene-o-diamine* forms  $C_{18}H_{16}<\begin{smallmatrix} C:N \\ C:N \end{smallmatrix}>C_6H_5$ , crystallising in needles [164°], insol. water, sl. sol. alcohol, v. sol. ether, resinified by strong acids.—9. Alcoholic ammonia added to a solution of the quinone in chloroform slowly forms the imide  $C_{18}H_{16}O(NH)$ , crystallising in unstable golden needles.—10. Aqueous  $SO_2$  forms hydrotenequinone  $C_{18}H_{16}<\begin{smallmatrix} C:OH \\ C:OH \end{smallmatrix}>$ , crystallising in white plates, sol. alcohol and alkalis. The same body is got by reducing the quinone with  $Zn$  and  $NaOHAq$ . It is oxidised by air to retenequinone.

**Oxim**  $C_{18}H_{16}O(NOH)$ . [128.5°]. Golden needles (from alcohol), decomposed by acids into the quinone and hydroxylamine. Forms green compounds with iron mordants (Von Kostanecki, *B.* 22, 1347).

**RETENE DISULPHONIC ACID**  $C_{18}H_{16}(SO_3H)_2$ . S. c. 40 in the cold. Formed by sulphonation (Ekstrand, *A.* 185, 86). Needles (containing 10 aq), v. sol. water and alcohol. Its aqueous solution is ppd. by  $H_2SO_4$ , forming

$H_2A''5H_2SO_4$ , crystallising in hair-like needles.— $K_2A''$ aq (dried at 100°). S. c. 18. Small silky needles.— $Na_2A''$ aq (dried at 100°). S. c. 40 in the cold.— $BaA''$ aq. S. 1.6.— $SrA''$ aq. S. 4.— $CaA''$ aq. S. 5.— $MgA''$ aq (dried at 100°). S. 4.— $CuA''$ aq: long needles. S. c. 30.— $PbA''$ aq (dried at 100°). S. 2.

**Chloride**  $C_{18}H_{16}(SO_2Cl)_2$ . [175°]. Prisms (from  $HOAc$ ).

**Retene trisulphonic acid**  $C_{18}H_{16}(SO_3H)_3$ . Got by heating retene with fuming  $H_2SO_4$  at 100°. Crystalline mass, v. sol. water, alcohol, and ether; not ppd. by  $H_2SO_4$ .— $Ba_3A'''$ aq. Needles. S. 7.— $Pb_3A'''$ aq: slender needles.

**RETENIC ACID**  $C_{18}H_{16}O_2$ . [222°]. A product of oxidation of retene (Ekstrand, *A.* 185, 111). Needles (from alcohol), v. sol. alcohol, ether, and  $HOAc$ . May be sublimed.— $NaA$ : plates, m. sol. water.

**RETINAPHTHA** is **TOLUENE**.

**RETINDOLE** v. **INDOLE**.

**RETISTENE** is **RETENE**.

**RHAMNETIN** is the *Methyl ether of QUERCETIN* (q.v.).

**RHAMNITE**  $C_8H_8O_2$  i.e.

$CH_3.CH(OH).CH(OH).CH(OH).CH(OH).CH_2OH$ . [121°].  $[\alpha]_D = 10.7^\circ$ . Formed by reducing isodulcitate with sodium-amalgam in a solution kept nearly neutral by  $H_2SO_4$  (E. Fischer a. Piloty, *B.* 23, 3104). Triclinic crystals, with sweet taste, v. sol. water and alcohol, sl. sol. chloroform, v. sl. sol. ether. Dextrorotatory. Does not reduce Fehling's solution.

**RHAMNOHEPTOSE**  $C_8H_{16}O_7$  i.e.

$CH(OH).CH(OH).CH(OH).CH_2$   
 $CH(OH).CH(OH).CH(OH).CHO$ .  $[\alpha]_D = 8^\circ$ . Formed by the action of sodium-amalgam on the lactone, [c. 160°],  $[\alpha]_D = 55.6^\circ$ , of hexa-oxy-octoic acid, which is formed from rhamnohexose by successive treatment with  $HCl$  and *baryta* (Fischer a. Piloty, *B.* 23, 3106). Sweet syrup. Dextrorotatory. Yields  $C_{12}H_{12}O_6(N_2HPH)$  [200°] and  $C_8H_8O_6(N_2HPH)_2$  [c. 200°]. Converted by treatment with  $HCl$ , followed by saponification, into hepta-oxy-annoic acid  $CH(OH).CH(OH).CH(OH).CH_2$   
 $CH(OH).CH(OH).CH(OH).CH(OH).CO_2H$  the lactone of which [c. 172°] is levorotatory  $[\alpha]_D = -51^\circ$ .

**RHAMNOHEXITE**  $C_8H_{16}O_6$  i.e.

$CH(OH).CH(OH).CH(OH).CH_2$   
 $CH(OH).CH(OH).CH_2(OH)$  [c. 173°].  $[\alpha]_D = 11.6^\circ$ . Formed by reducing rhamnohexose with sodium-amalgam (Fischer a. Piloty, *B.* 23, 3106). Small colourless prisms (from hot alcohol). Does not reduce Fehling's solution.

**RHAMNOHEXOSE**  $C_8H_{16}O_6$  i.e.

$CH_3.CH(OH).CH(OH).CH(OH).CH(OH).CH_2$   
 $CH(OH).CH(OH).CH_2(OH)$  [181°].  $[\alpha]_D = -61^\circ$ . Formed by reducing the lactone of isodulcitate carboxylic acid with sodium-amalgam in acid solution at a low temperature (Fischer a. Piloty, *B.* 23, 3104). Small tables, sl. sol. alcohol. Its aqueous solution tastes sweet. Yields a di-phenyl-di-hydrazide [200°].

**RHAMNOSE** v. **ISODULCITE**.

**RHATANINE**  $C_{19}H_{18}NO_6$ . S. 8 at 100°. S (alcohol) 0.1 at 15°; 0.4 at 78°. Occurs in the extract of rhatany root (Wittstein, *J.* 1854, 656; Ruge, *Viertelj. d. nat. Ges. in Zurich*, 6, Helt 3; Gintl, *Sitz. W.* [2] 60, 668; Kreitmair, *A.* 176, 69). Spherical groups of white needles,  $\mu D$

insol. ether. Not pptd. by lead acetate or subacetate. Resembles tyrosine. On heating with a little solution of  $\text{Hg}(\text{NO}_3)_2$  it becomes rose-red, and gives a brown pp. on further addition of  $\text{Hg}(\text{NO}_3)_2$ . Boiling  $\text{HNO}_3$  gives a red colour changing to blue, and finally to a fluorescent green. Sulphuric acid forms a sulphonic acid  $\text{C}_{10}\text{H}_7\text{NO}_6(\text{SO}_3\text{H})$  aq crystallising from alcohol in plates yielding  $\text{BaA}'_2 \cdot 2\frac{1}{2}\text{aq}$  and  $\text{BaA}'_2 \cdot 5\text{aq}$ .

Salts.— $\text{H}_2\text{A}''\text{HCl}$ : monoclinic prisms, decomposed by treatment with water or alcohol.— $(\text{H}_2\text{A}'')_2\text{H}_2\text{PtCl}_6 \cdot \text{Na}_2\text{A}''$ : deliquescent amorphous mass.— $\text{KA}''$ .— $\text{BaA}'' \cdot 2\text{aq}$ .— $\text{SrA}'' \cdot 2\text{aq}$ .— $\text{CaA}''$ .— $\text{MgA}''$ .— $\text{Ag}_2\text{A}''$ : minute needles, sl. sol. cold water.— $\text{H}_2\text{A}''\text{HNO}_3$ .— $\text{H}_2\text{A}''\text{H}_2\text{SO}_4$ : trimetric crystals.— $\text{H}_2\text{A}''\text{H}_3\text{PO}_4$ : small prisms.

**RHATANITANNIC ACID**  $\text{C}_{10}\text{H}_{10}\text{O}_6$  (Raabe, J. 1880, 1060). Occurs in rhatany extract from the root-bark of *Krameria triandra* (Wittstein, J. 1854, 656; Grabowski, A. 143, 274). Amorphous, sol. water. Reduces Fehling's solution. Gives a dark-green colour with  $\text{FeCl}_3$ . Yields phloroglucin and protocatechuic acid on fusion with potash. Boiling dilute  $\text{H}_2\text{SO}_4$  forms 'rhatania-red'  $\text{C}_{10}\text{H}_{10}\text{O}_6$ , which yields pyrocatechin on distillation.

**RHINACANTHIN**  $\text{C}_{11}\text{H}_{10}\text{O}_6$ . Occurs in the root of *Rhinanthus communis* (Liberius, J. 1881, 1022). Tasteless resin, sol. alcohol. Does not form glucose on boiling with  $\text{HClAq}$ .

**RHINANTHIN**  $\text{C}_{20}\text{H}_{32}\text{O}_{26}$  (L.) or  $\text{C}_{41}\text{H}_{50}\text{O}_{40}$ . A glucoside occurring in the seeds of the yellow rattle (*Rhinanthus crista-galli*), and giving rise to the violet colour of bread prepared from rye contaminated with these seeds. Occurs also in the seeds of *Alectrolophus hirsutus* (Ludwig, Z. [2] 5, 303; Ar. Ph. [2] 142, 199), and in the leaves and stalks of the snap-dragon (*Antirrhinum majus*) (Phipson, C. N. 58, 99). Stellate groups of prisms, with bitter-sweet taste, v. sol. water and alcohol. Gives a bluish-green solution on warming with alcoholic  $\text{HCl}$ . Resolved by dilute  $\text{HClAq}$  into brown amorphous rhinanthogen and a sugar.

**RHIZOPOGONIC ACID**  $\text{C}_{20}\text{H}_{20}\text{O}_6$ . [127°]. Obtained from the mushroom *Rhizopogon rubescens* by extracting with ether (Oudemans, R. T. C. 2, 155). Red needles, insol. water, v. e. sol. ether, chloroform, and boiling alcohol. Its alkaline solutions are intensely violet.— $\text{KA}'$  aq: minute dark-violet crystals.

**RHODAMMINES** v. RHODIUM-AMMONIUM COMPOUNDS, p. 405.

**RHODANIDES**, another name for Sulphocyanides (q. v. vol. II. p. 348).

**RHODANIC ACID**  $\text{C}_2\text{H}_3\text{NS}_2\text{O}$  i.e.

$\text{HS} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{S} \cdot \text{CN}$  or  $\text{CH}_2 \cdot \begin{smallmatrix} \text{S} \cdot \text{CS} \\ \text{CO} \cdot \text{NH} \end{smallmatrix}$  (Andreasch, M. 10, 73). [169°]. Formed by warming an aqueous solution of chloro-acetic acid (1 mol.) with ammonium sulphocyanide (3 mols.) (Nencki, J. pr. [2] 16, 1; B. 17, 2279; Ginsberg a. Bondzynski, B. 19, 113). Formed also by passing  $\text{HCl}$  into an alcoholic solution of thioglycollic acid and potassium sulphocyanide (Freydl, M. 10, 82). Yellow six-sided prisms and tables, v. sl. sol. cold water, v. sol. alcohol and ether. Acid in reaction. Boiling baryta-water splits it up into  $\text{HCyS}$  and thioglycollic acid. Water at 200° forms  $\text{CO}_2$ ,  $\text{H}_2\text{S}$ ,  $\text{NH}_3$ , and thioglycollic acid. Reacts with aldehydes in presence of  $\text{HCl}$ , form-

ing compounds of the type  $\text{R} \cdot \text{CH} \cdot \text{C}(\text{SH}) \cdot \text{CO} \cdot \text{S} \cdot \text{CN}$ . Ethylidene-rhodanic acid  $\text{C}_2\text{H}_5\text{NS}_2\text{O}$  [148°] forms yellow needles, sol. hot water. Benzylidene-rhodanic acid  $\text{C}_{10}\text{H}_7\text{NS}_2\text{O}$  [200°] also forms yellow needles, converted by hot  $\text{H}_2\text{SO}_4$  (4 pts.) into  $\text{C}_{10}\text{H}_7\text{NS}_2\text{O}$ , crystallising in needles, yielding  $\text{NaA}'$ ,  $\text{KA}'$ , and  $\text{NH}_4\text{A}'$ , and converted by  $\text{HNO}_3$  into  $\text{C}_{10}\text{H}_7\text{NS}_2\text{O}$ , crystallising in yellow needles yielding  $\text{NaA}'$  aq. o-Nitro-benzylidene-rhodanic acid  $\text{C}_{10}\text{H}_6\text{N}_2\text{S}_2\text{O}$  [189°] crystallises from dilute alcohol, and may be reduced to o-amido-benzylidene-rhodanic acid, which yields  $\text{C}_{10}\text{H}_6\text{AcN}_2\text{S}_2\text{O}$  [280°–285°] and  $\text{C}_{10}\text{H}_6\text{Ac}_2\text{N}_2\text{S}_2\text{O}$  [189°]. p-Nitro-benzylidene-rhodanic acid [252°] is also crystalline (Bondzynski, M. 8, 357).  $\text{FeCl}_3$  added to a hot solution of rhodanic acid forms a brown pp., from which alcohol extracts  $\text{C}_{10}\text{H}_7\text{NS}_2\text{O}$ , as a brownish-red powder, forming a red solution in alkalis.

Salts.— $\text{CuA}'_2$  aq: yellowish-green amorphous pp.— $(\text{C}_2\text{H}_5\text{NS}_2\text{O})_2\text{CuCl}$ : golden needles.

**RHODATES**. No salts have been isolated the acidic radicle of which is composed of Rh and O; but there is some reason to think that such salts exist in the solution obtained by passing Cl into an alkaline solution of  $\text{Rh}_2(\text{OH})_6$ ; v. under HYDRATED RHODIUM DIOXIDE, p. 405.

**RHODINOL**  $\text{C}_{11}\text{H}_{18}\text{O}$  i.e.

$\text{CH}_2 \cdot \text{C}(\text{C}_2\text{H}_5) \cdot \text{CH} \cdot \text{CH} \cdot \text{CHMe} \cdot \text{CH}_2 \cdot \text{OH}$ . (217°). S.G. 1.88. Occurs in German and Turkish oil of roses (Eckart, B. 24, 4205). Oxidised by chromic acid mixture to an aldehyde, rhodinol, and rhodinolic acid.  $\text{P}_2\text{O}_5$  yields a terpene.  $\text{KMnO}_4$  forms valeric, butyric, acetic, oxalic, and carbonic acids and  $\text{C}_8\text{H}_8\text{O}_4$ , possibly an alcohol.

**RHODIUM**. At. w. 102.7. Mol. w. unknown. Melts at c. 2000° (Pictet, C. R. 88, 1317). S.G. 12.1 (Deville a. Debray, J. 12, 240). S.H. -0.5803 (10° to 97°; specimen contained trace of Ir) (Regnault, A. Ch. [3] 63, 1). C.E. -0.000085 at 40° (Fizeau, C. R. 68, 1125).

Occurrence.—With the other Pt metals in platinum-ore; the p.c. of Rh varies from 0 to c. 5; as much as 12.3 p.c. was found in a South American ore by Deville a. Debray (A. Ch. [2] 29, 187; cf. Kern, C. N. 35, 88).

Del Río (v. D. a. D., l.c.) found an alloy of Rh and Au in Mexico, containing from 34 to 43 p.c. Rh. Rhodium was separated from the other Pt metals in 1803 by Wollaston (T. 1804. 419), at the same time as he isolated Pd. The name *rhodium* was given by W. because of the rose-colour of the salts ( $\rho\acute{\alpha}\delta\delta\omicron\nu$  = a rose).

Formation.—1. By reducing  $\text{RhCl}_3 \cdot 3\text{NaClAq}$  by Zn, H, formic acid, &c.—2. By strongly heating  $\text{RhCl}_3 \cdot 3\text{NH}_4\text{Cl}$ .

Preparation.—Rh is generally prepared by adding iron to the mother-liquors from which Pt has been extracted (v. PLATINUM, this vol. p. 286), and then treating the solid so pptd. The processes for the treatment of this residue are many; that described here is the one employed by Claus (J. pr. 85, 129), and by Gibbs (J. pr. 84, 65; 94, 19), and is a modification of Claus's older method (cf. Deville a. Debray, C. R. 78, 1782). The platinum-residue—which contains Rh, Ru, Pd, Ir, Cr, Cu, and Pb—is fused at a bright red heat with 1 pt. Pb and 1 pt.  $\text{PbO}$ ; the regulus, after separation of slag, is treated with nitric acid (equal vols. conc. acid and water); the insoluble residue is washed, dried, and mixed

with its own weight of NaCl, and this mixture is heated to low redness, in a large porcelain tube, in a stream of Cl, for some time; the treatment with NaCl and Cl is repeated; after cooling, the contents of the tube are lixiviated with water, when  $\text{RhCl}_3 \cdot 3\text{NaCl}$  dissolves with small quantities of the corresponding salt of Ir and traces of some of the other metals. The solution is heated with  $\text{HNO}_3\text{Aq}$ , to transform  $\text{IrCl}_3$  into  $\text{IrCl}_4$ , and Ir is then removed, as  $\text{IrCl}_3 \cdot 2\text{AmCl}$ , by fractional ppn. with conc.  $\text{AmClAq}$ . The filtrate from the last pp. of  $\text{IrCl}_3 \cdot 2\text{AmCl}$ , which is almost quite free from all metals except Rh, is evaporated to dryness with  $\text{HNO}_3\text{Aq}$ , to decompose the  $\text{AmCl}$ ; the residue is mixed with 3 or 4 times its weight of S, and heated to bright redness in a covered porcelain crucible, which is packed in powdered charcoal in a larger earthen crucible. The regulus thus obtained is boiled for some time with *aqua regia*, and then with conc.  $\text{H}_2\text{SO}_4$ ; it is then fused, at a low red heat, with 3 or 4 pts. Zn, whereby an alloy of Rh and Zn is formed, with the production of so much heat that part of the Zn is volatilised. After cooling, the alloy is digested with conc.  $\text{HClAq}$ , to remove impurities, and is then dissolved in *aqua regia*.  $\text{NH}_3\text{Aq}$  is added to this solution till the pp. which forms has dissolved; the solution is boiled, and evaporated until yellow  $\text{Rh}_2(\text{NH}_3)_6\text{Cl}_6$  separates; the whole is then evaporated to dryness at  $100^\circ$ , and the residue is treated with warm dil.  $\text{HClAq}$  until the washings show no yellow colour; the residue is dissolved in boiling water, and the liquid is filtered, hot, into dil.  $\text{HClAq}$ ; the small yellow crystals of  $\text{Rh}_2(\text{NH}_3)_6\text{Cl}_6$ , which separate are re-crystallised several times from hot, dil.  $\text{NH}_3\text{Aq}$ , whereby the salt is obtained quite pure. The pure  $\text{Rh}_2(\text{NH}_3)_6\text{Cl}_6$  is decomposed by heating strongly in a graphite crucible, and the Rh thus obtained is fused in a lime crucible in the O-H flame (v. vol. iii. p. 642). The fusion removes the last traces of Os and Si. For other methods of preparing Rh v. Bunsen, A. 146, 265; Fremy, C. R. 38, 1008; Lea, Am. S. 38, 81, 248; Schneider, P. Supp. 5, 261; Philipp, D. P. J. 220, 95; Martius, A. 67, 357; Wilm, Bl. [2] 34, 679.

**Properties.**—A very hard, white metal, with a tinge of blue-grey; about as ductile and malleable as Ag. Melts only in the full O-H flame, without volatilising; spits on cooling; is superficially oxidised when very strongly heated in air. Insoluble in acids when compact, but the finely divided metal ppd. from solutions is sol.  $\text{HNO}_3\text{Aq}$ , and also sl. sol.  $\text{HClAq}$  in presence of air (Wilm, Bl. [2] 34, 679). Alloys of Rh with Bi, Cu, Pb, Pt, or Zn are attacked by  $\text{HNO}_3\text{Aq}$ . Rh is obtained as a black porous solid by reducing solutions of Rh compounds by Zn, Hg, EtOH, or  $\text{HCO}_2\text{H}$  (v. Claus, J. pr. 85, 139; Wilm, l.c.). The finely divided Rh obtained by heating the purpureochloride takes up c. 13 p.c. O when heated in a stream of air ( $\text{RhO}$  requires 13.5 p.c. O), and the O is given up by heating in H.

In its chemical relationships Rh is closely allied to Ru and Pd, and less closely to Os, Ir, and Pt; v. NOBLE METALS, vol. iii. p. 623.

The at. w. of Rh has been determined (1) by analyses of  $\text{RhCl}_3 \cdot 3\text{KCl}$  (Berzelius, P. 13, 442 [1828]); (2) by analyses of a large number of

different Rh compounds (Claus, J. pr. 85, 139 [1862]); (3) by analyses of  $\text{Rh}_2(\text{NH}_3)_6\text{Cl}_6$  and  $\text{Rh}_2(\text{NH}_3)_6\text{Br}_6$  (Jørgensen, J. pr. [2] 27, 433, 489 [1883]); (4) by reducing pure  $\text{Rh}_2(\text{NH}_3)_6\text{Cl}_6$  in H, and determining the residual Rh (Seubert a. Kobbé, A. 260, 314 [1890]); (5) by determining S.H. of Rh (Regnault, A. Ch. [3] 63, 1). No compound of Rh has been gasified. The older values for at. w. of Rh varied from 104.3 to 103. Seubert a. Kobbé have shown that the true value is less than 103.

**Reactions and Combinations.**—1. Rhodium black heated in air combines with O to form  $\text{RhO}$ , according to Wilm (B. 15, 2225). Leidié (Bl. [2] 50, 664) says that the products contain from 14.5 to 17.8 p.c. O ( $\text{RhO}$  requires 13.5 p.c. O).—2. Oxidised to  $\text{Rh}_2\text{O}_3$ , and then to  $\text{RhO}_2$ , by fusion with potash and nitre (Claus, l.c.); also by heating strongly with barium peroxide (D. a. D., l.c.).—3. Fusion of Rh black with potassium-hydrogen sulphate produces what is probably a double Rh-K sulphate (Claus, l.c.).—4. Heated in chlorine to c.  $400^\circ$ ,  $\text{RhCl}_3$  is formed (v. Leidié, Bl. [2] 50, 664).—5. Mixed with scdium-chloride and heated in chlorine,  $\text{RhCl}_3 \cdot 3\text{NaCl}$  is produced; KCl and Cl, and BaCl, and Cl, act similarly (Berzelius, P. 13, 435; Bunsen, A. 146, 260).—6.  $\text{RhS}$  is formed by heating Rh black in vapour of sulphur (B., l.c.).—7. Rh dissolves in mollen phosphoric acid (Fischer, P. 18, 257), also in mollen acid phosphates (Rose-Finkner, Hand. d. anal. Chem. 6th ed., 1, 354).—8. Finely divided Rh dissolves in mollen zinc (Jørgensen, J. pr. [2] 27, 433, 489).—9. Hydrogen is absorbed in large quantities by Rh. The finely divided metal obtained by heating  $\text{RhCl}_3 \cdot 3\text{AmCl}$  becomes sensibly hot when H is passed over it (Wilm, l.c.).—10. Rh black decomposes chlorine water, forming  $\text{HClAq}$  and O, and solutions of hypochlorites, forming chlorides and O (Jørgensen, l.c.). It also decomposes hydrogen peroxide, giving off O.—11. Rh black decomposes formic acid solution to H and  $\text{CO}$ ; alcohol in presence of alkali is oxidised to alkali acetate, and H is given off, at c.  $30^\circ$  (D. a. D., A. Ch. [2] 29, 137; 56, 385; cf. Hoppe-Seyler, B. 16, 117).—12. When Rh black obtained by heating  $\text{RhCl}_3 \cdot 3\text{AmCl}$  is heated in coal-gas, or in ethylene, the volume of the Rh increases and C is absorbed (Wilm, Bl. [2] 34, 679).

**Detection.**—Rh may be brought into solution in water, either by repeated fusion with  $\text{KHSO}_4$ , or by mixing with NaCl and heating to low redness in Cl. To detect Rh in solution, Demarcay (C. R. 101, 951) recommends to add  $\text{AmCl}$  to a neutral, or an almost neutral, solution which has been boiled with  $\text{HClAq}$ , then to add fairly conc. freshly prepared  $\text{NaClOAg}$ , and then a 20 p.c. acetic acid solution, drop by drop, with constant shaking, till any pp. formed by the  $\text{NaClOAg}$  dissolves to an orange-coloured solution; on standing, this solution decolourises, deposits a greyish pp., and finally acquires an intense sky-blue colour, which remains for some time. Free  $\text{HNO}_3$ , or  $\text{H}_2\text{SO}_4$ , should be absent, not much acetic acid should be added, and the temperature should not be raised. By taking two equal portions of the liquid to be tested, diluting one with water to the same bulk as the other occupies when the reagents are added, and comparing the two, .00019 g. Rh can be

detected in 3 c.c. liquid. The other Pt metals give no reaction with  $\text{NaClO}_4\text{aq}$  under the above conditions.

**Rhodium, alloys of.** Rh alloys with many metals, by fusion with them. Some of the alloys seem to have definite compositions, e.g.  $\text{Rh}_2\text{Pb}$  and  $\text{RhZn}_2$ . Descriptions of the alloys will be found in the papers referred to:—As (Wollaston, *T.* 1804. 419); Bi (W., *l.c.*); Au (W., *l.c.*; van Riemsdyk, *J.* 1880. 1269); Fe (Faraday a. Stodart, *G. A.* 66, 167); Pb (Debray, *C. R.* 90, 1195; Deville a. D., *C. R.* 44, 1101; 94, 1557); Pt (D. a. D., *l.c.*); Ag (W., *l.c.*); Sn (D., *l.c.*; Leidié, *C. R.* 106, 1076); Zn (D. a. D., *l.c.*; Bunsen, *A.* 146, 271; Jörgensen, *J. pr.* [2] 27, 434).

**Rhodium, ammonio-salts of, v. RHODIUM-AMMONIUM COMPOUNDS, p. 405.**

**Rhodium, chlorides of.** The only chloride of Rh which has been isolated with certainty is  $\text{RhCl}_3$ . The lower chloride  $\text{RhCl}_2$  probably exists.

**RHODIUM DICHLORIDE  $\text{RhCl}_2$ .** This chloride probably exists. Berzelius obtained a greyish-red powder, to which he gave this composition, by heating Rh in Cl, warming the product with  $\text{KOH aq}$ , and treating the hydrated oxide so formed with  $\text{HCl aq}$ , when  $\text{RhCl}_2$  dissolved and  $\text{RhCl}_3$  (?) remained (*P.* 13, 437). According to Fellenberg (*P.* 50, 63)  $\text{RhCl}_2$  is obtained, as a rose-red powder, insol. water,  $\text{HCl aq}$ , or  $\text{HNO}_3\text{aq}$ , undecomposed by  $\text{KOH aq}$ , by heating Rh in Cl. Claus (*J.* 1855. 423) and Leidié (*C. R.* 106, 1076; 107, 234) regard the existence of  $\text{RhCl}_2$  as unproved. According to L., no substance of constant composition is obtained by F.'s method.

(?) Double salt,  $\text{Am}_2\text{RhCl}_6 \cdot x\text{H}_2\text{O}$ . The compound to which Wilm gave this composition, and which he said was obtained by adding  $\text{AmCl}$  to  $\text{RhCl}_2\text{aq}$  in presence of much *aqua regia* (*B.* 16, 3033), is almost certainly identical with  $\text{Am}_2\text{RhCl}_6 \cdot \text{NH}_4\text{NO}_3 \cdot 3\frac{1}{2}\text{H}_2\text{O}$ , obtained by Leidié (v. AMMONIUM CHLOR-RHODITE, *infra*).

**RHODIUM TRICHLORIDE  $\text{RhCl}_3$  (Rhodo-chloride. Rhodo-rhodic chloride,  $\text{RhCl}_3 \cdot \text{RhCl}_2$ ,  $\text{Rhodium sesquichloride}$ ,  $\text{Rh}_2\text{Cl}_5$ ).**  $\text{RhCl}_3$  is the simplest formula possible, but it is not necessarily molecular. Leidié (*C. R.* 106, 1076; 107, 234) prepared  $\text{RhCl}_3$  by heating the alloy  $\text{RhSn}$ , in a rapid stream of dry, air-free Cl at the B. P. of S, until  $\text{SnCl}_2$  ceased to be formed, allowing to cool, and removing Cl by a current of  $\text{CO}_2$ . The chloride is thus obtained as a sealing-wax-red powder. The alloy  $\text{RhSn}$ , is formed by fusing 1 part finely divided Rh with 30 to 50 parts Sn, and treating the product for a day or two with fairly conc.  $\text{HCl aq}$  at  $0^\circ$  (Debray, *C. R.* 104, 1470, 1577).  $\text{RhCl}_3$  was also formed by Jörgensen (*J. pr.* [2] 27, 433) by heating  $\text{Cl}_2\text{Rh}(\text{NH}_3)_3\text{Cl}$  in a stream of Cl. Leidié (*Bl.* [2] 50, 664) says that  $\text{RhCl}_3$  is not obtained pure by Claus' method of heating Rh in Cl, as part of the  $\text{RhCl}_3$  is decomposed at the temperature which must be employed to cause combination of Rh and Cl. Leidié (*l.c.*) could not obtain pure  $\text{RhCl}_3$  by heating  $\text{Rh}_2\text{S}_3$  in Cl, nor by heating the double chlorides of Rh and alkali metals with  $\text{H}_2\text{SO}_4$ , as recommended by Claus; in the latter reactions L. obtained alkali sulphate and  $\text{Rh}_2(\text{SO}_4)_3$ .  $\text{RhCl}_3$  is a red powder, insol. water and acids; decomposes to Rh and

Cl at c.  $450^\circ$ – $500^\circ$  (L., *l.c.*). When moist  $\text{RhCl}_3$  is heated *in vacuo*, or in a stream of N, it is partially decomposed at  $100^\circ$ , and wholly at  $360^\circ$ , to  $\text{Rh}_2\text{O}_3$  and  $\text{HCl}$  (L., *l.c.*). Slowly reduced by H at low redness (v. Claus, *J.* 1855. 423).

**HYDRATE OF RHODIUM TRICHLORIDE  $\text{RhCl}_3 \cdot 4\text{H}_2\text{O}$ .** Said to be formed by Claus (*l.c.*) by dissolving freshly ppd.  $\text{Rh}(\text{OH})_3$  in  $\text{HCl aq}$ , and evaporating; by Berzelius (*P.* 13, 437) by decomposing  $\text{K}_2\text{RhCl}_6\text{aq}$  by  $\text{H}_2\text{SiF}_6\text{aq}$ , filtering, and evaporating. Described as a dark-red, glassy, deliquescent solid; s. sol. alcohol, insol. ether. Leidié (*Bl.* [2] 50, 664) could not obtain this, nor any definite hydrate of  $\text{RhCl}_3$ .

**Double salts. Chloro-rhodites**

$\text{RhCl}_3 \cdot 3\text{MCl}$ , or  $\text{M}_2\text{RhCl}_6$ .  $\text{M} = \text{Am}, \frac{1}{2}\text{Ba}, \frac{1}{2}\text{Pb}, \text{Hg}, \text{K}, \text{Ag}, \text{Na}$ . Also  $\text{M}_2\text{RhCl}_6$ ;  $\text{M} = ?\text{Am}$ , and K.

**Ammonium chlor-rhodite  $2\text{Am}_2\text{RhCl}_6 \cdot 3\text{H}_2\text{O}$  (Ammonium-rhodium trichloride).** Large, red, rhombic prisms (v. Kefenstein, *P.* 99, 275); by adding conc.  $\text{HCl aq}$  to  $\text{Na}_2\text{RhCl}_6\text{aq}$ , filtering from  $\text{NaCl}$ , and adding conc.  $\text{AmCl aq}$  (Claus, *l.c.*; Wilm, *B.* 16, 3033; Leidié, *l.c.*). Sol. water, or dil.  $\text{AmCl aq}$ ; insol. alcohol. The salt  $\text{Am}_2\text{RhCl}_6 \cdot \text{H}_2\text{O}$ , said to be formed by heating a solution of the preceding salt (Vauquelin, *A. Ch.* 93, 204), could not be obtained by Leidié (*l.c.*).

Double salt with ammonium nitrate,  $2(\text{Am}_2\text{RhCl}_6 \cdot \text{NH}_4\text{NO}_3) \cdot 7\text{H}_2\text{O}$ . Obtained, as violet-red crystals, by adding  $\text{HNO}_3\text{aq}$  to  $\text{Am}_2\text{RhCl}_6\text{aq}$ , and then excess of  $\text{AmCl aq}$ , concentrating, and drying the crystals *in vacuo*. Scarcely sol.  $\text{HNO}_3\text{aq}$ ; when boiled with water gives off same gases as are obtained by boiling  $\text{AmCl aq}$  with *aqua regia*.

**Potassium chlor-rhodites** (1)  $\text{K}_2\text{RhCl}_6 \cdot 3\text{H}_2\text{O}$ . Dark-red triclinic prisms; by adding conc.  $\text{KCl aq}$  to  $\text{RhCl}_2\text{aq}$ , and allowing to evaporate (Claus, *l.c.*). Obtained by Seubert a. Kobbé (*B.* 23, 2556) by saturating the filtrate from the salt  $\text{K}_2\text{RhCl}_6$  (*infra*) with  $\text{HCl}$ , filtering from  $\text{KCl}$ , and evaporating. Leidié (*l.c.*) failed to obtain this salt.

(2)  $\text{K}_2\text{RhCl}_6 \cdot \text{H}_2\text{O}$  (no water, according to L.). Brown triclinic prisms, sl. sol. water. Gives Rh,  $\text{KCl}$ , and Cl when heated to redness. Formed by heating a mixture of 1 part spongy Rh with 2 parts  $\text{KCl}$ , in a stream of Cl, so long as Cl is absorbed, dissolving in water, filtering, and evaporating under reduced pressure (S. a. K., *l.c.*).

**Sodium chlor-rhodite  $\text{Na}_2\text{RhCl}_6 \cdot 9\text{H}_2\text{O}$ .** Prepared like the K salt (Berzelius, Claus, Leidié).

The lead, mercurous, and silver salts are obtained by adding  $\text{Pb}(\text{NO}_3)_2\text{aq}$ ,  $\text{HgNO}_3\text{aq}$ , or  $\text{AgNO}_3\text{aq}$ , to solution of an alkali salt (Claus, *l.c.*). The barium salt is obtained like the K and Na salts (Bunsen, *A.* 146, 276). Compounds of  $\text{RhCl}_3$  with methylamine chlorides are described by Vincent (*Bl.* [2] 44, 513).

**Rhodium, cyanides of, and derivatives, v. vol. ii. p. 346.**

**Rhodium, hydrosulphide of,  $\text{RhS}_2\text{H}_4$  ( $=\text{Rh}_2\text{S}_3 \cdot 3\text{H}_2\text{S}$ ).** A brownish-black, voluminous pp., obtained by passing  $\text{H}_2\text{S}$  into solution of a Rh salt at c.  $100^\circ$  (Leidié, *Bl.* [2] 50, 664). Insol. acids, or alkali sulphide solutions; decomposed by Br and *aqua regia*. Gives off  $\text{H}_2\text{S}$ , and forms  $\text{Rh}_2\text{S}_3$  when boiled with much water in N, or when heated with water in a sealed tube to  $100^\circ$ .

**Rhodium, hydroxides of, v. RHODIUM OXIDES AND HYDRATED OXIDES.**

**Rhodium, iodide of.** The black substance obtained by Jørgensen in making  $\text{Rh}_2(\text{NH}_3)_{16}\text{I}_2$  (v. IODOPURPURORHODIUM IODIDE, p. 406) was probably  $\text{RhI}_3$ ; analysis gave 21.8 p.c. Rh, the formula requiring 21.3 p.c. According to Claus (l.c.) an iodide of Rh is formed when  $\text{KIAq}$  is added to solution of a salt of Rh.

**Rhodium, oxides and hydrated oxides of.** Rh and O combine, when Rh is strongly heated in O, probably with formation of  $\text{RhO}$ . The only oxides of Rh which have been isolated with certainty are  $\text{Rh}_2\text{O}_3$  and  $\text{RhO}_2$ ;  $\text{RhO}$  also probably exists, and there are indications of the formation of  $\text{Rh}_2\text{O}_3$ . The hydrated oxides, or hydroxides, are  $\text{Rh}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  [ $=\text{Rh}(\text{OH})_3$ ], and  $\text{Rh}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$  [ $=\text{Rh}(\text{OH})_2$ ].

**Rhodium monoxide  $\text{RhO}$  (Rhodous oxide).** Probably formed when Rh black is heated in a stream of air (Wilm, B. 15, 2225). Leidié (Bl. [2] 50, 664) says that from 14.5 to 17.8 p.c. O is taken up;  $\text{RhO}$  requires 13.5 p.c. O. The grey powder obtained by heating  $\text{Rh}(\text{OH})_3$  was looked on by Claus as probably  $\text{RhO}$ . Deville and Debray (A. Ch. [3] 61, 83) obtained what they regarded as  $\text{RhO}$  containing a little  $\text{PbO}$  by melting Rh with  $\text{PbO}$ , Pb, and borax, cupelling, and treating the residue with  $\text{HNO}_3\text{Aq}$ .  $\text{RhO}$  is said to be fairly easily reduced to Rh by heating in H.

**Rhodium sesquioxide  $\text{Rh}_2\text{O}_3$  (Rhodo-rhodic oxide).** This oxide may be formed when Rh black is heated to redness in air. Leidié found from 14.5 to 17.8 p.c. O taken up (Bl. [2] 50, 664);  $\text{Rh}_2\text{O}_3$  requires 18.92 p.c. O.  $\text{Rh}_2\text{O}_3$  was obtained by Claus (J. pr. 76, 24; 80, 232; 85, 129) by heating  $\text{Rh}(\text{NO}_3)_3$  in a Pt crucible till oxides of N ceased to come off; also by fusing Rh with  $\text{BaO}_2$  and  $\text{Ba}(\text{NO}_3)_2$ . Freymy (A. Ch. [3] 44, 385) says that  $\text{Rh}_2\text{O}_3$  is produced by heating  $\text{Na}_2\text{RhCl}_6$  to redness in a stream of O.  $\text{Rh}_2\text{O}_3$  is also formed by heating  $\text{Rh}_2\text{O}_3\text{H}_2$ .  $\text{Rh}_2\text{O}_3$  forms a grey solid; insol. acids; reduced by H to Rh (Claus, l.c.). Freymy obtained it as lustrous, metal-like, crystals, somewhat volatile when heated in a stream of O, which decomposed  $\text{ClAq}$  giving  $\text{HClAq}$  and O.

**HYDRATED RHODIUM SESQUIOXIDE.** (1)  $\text{Rh}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  (Rhodo-rhodic hydroxide,  $\text{Rh}_2\text{O}_3\text{H}_2$ ). A black gelatinous pp. formed by adding excess of  $\text{KOH}$  to  $\text{HClAq}$ , and a little alcohol, to  $\text{Na}_2\text{RhCl}_6\text{Aq}$ . Sl. sol. conc.  $\text{HClAq}$  (Claus, l.c.). (2)  $\text{Rh}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  (Hydrated rhodo-rhodic hydroxide,  $\text{Rh}_2\text{O}_3\text{H}_4$ ). Obtained by adding  $\text{KOH}$  to solution of  $\text{RhCl}_3$ , the latter being in excess, allowing to stand till the pp. is citron-yellow (the first rose-red pp. contains the hydrate mixed with  $\text{K}_2\text{RhCl}_6$ ), and washing with hot water (Claus, l.c.). The whole of the  $\text{KOH}$  cannot be removed from the pp. by washing. Sol.  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , and when freshly ppd. also in acetic acid. Also sol. conc.  $\text{KOH}$ aq, but reppd. on dilution (Desoutils, Gm.-K. 3, 1261). Said by Leidié (C. R. 107, 234) to be sol. in solution of alkali hydrogen oxalates. Solutions of this hydrate in acids yield the salts  $\text{Rh}_2\text{X}$  on evaporation;  $\text{X} = \text{NO}_3$ ,  $\text{C}_2\text{O}_4$ ,  $\text{SO}_4$ ,  $\text{SO}_3$ , &c.

**Rhodium dioxide  $\text{RhO}_2$  (Rhodi- or rhodic oxide).** A brown solid; obtained by repeatedly fusing finely divided Rh with  $\text{KOH}$  and  $\text{KNO}_3$ .

Insol. acids, or boiling  $\text{KOH}$ aq. Reduced to Rh by H at a high temperature (Claus, l.c.).

**HYDRATED RHODIUM DIOXIDE  $\text{RhO}_2 \cdot 2\text{H}_2\text{O}$  (Rhodic hydroxide,  $\text{RhO}_2\text{H}_2$ ).** Obtained by Claus (l.c.) by leading Cl into a solution of  $\text{Rh}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  in  $\text{KOH}$ aq till a dark-brown gelatinous pp. was formed, then adding pieces of  $\text{KOH}$  from time to time, and continuing the passage of Cl until pp. became more compact, and green, and the solution became blue-violet. A greenish solid, sol.  $\text{HClAq}$ , forming a greenish-blue solution, which evolves Cl and becomes the deep-red colour of  $\text{RhCl}_3$  solution (cf. Jørgensen, J. pr. [2] 27, 446).

**Rhodic acid and rhodates (?)**. The blue-violet solution obtained by passing Cl into  $\text{Rh}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  in  $\text{KOH}$ aq (*supra*) is fairly permanent, but after some time it ppts. a blue powder, gas is given off, and the liquid becomes colourless. When the blue powder is dried it becomes green  $\text{RhO}_2 \cdot 2\text{H}_2\text{O}$ . A blue pp. is also obtained by carefully neutralising the blue-violet solution by  $\text{HNO}_3\text{Aq}$ ; this powder, when moist, is sol.  $\text{HClAq}$ , with evolution of Cl; on heating, more Cl is evolved, and the liquid becomes the red colour of  $\text{RhCl}_3$  solution. Claus (l.c.) regarded the blue-violet solution as containing potassium rhodate, and the blue pp. he looked on as rhodium trioxide or rhodic anhydride,  $\text{RhO}_3$ .

**Rhodium, salts of.** But few salts are known obtained by replacing H of oxyacids by Rh; the chief are nitrate, nitrite, oxalates, phosphates, and sulphates; a few double salts are also known.

**Rhodium, sulphides of.** Rh and S combine when heated, probably forming  $\text{RhS}$ .  $\text{Rh}_2\text{S}_3$  is formed by ppn. from Rh salts.

**Rhodium monosulphide  $\text{RhS}$  (Rhodous sulphide).** Said by Berzelius to be formed by heating finely divided Rh in S vapour; also, according to Vauquelin (A. Ch. 88, 167), by heating  $\text{Am}_2\text{RhCl}_6$  with S. Fellenberg (P. 50, 63) obtained  $\text{RhS}$  by heating dry  $\text{Rh}_2\text{S}_3$  in  $\text{CO}_2$  (?). A white-blue, lustrous solid; heated in air gives spongy Rh; heated in Cl forms  $\text{RhCl}_3$  and  $\text{S}_2\text{Cl}_2$  (F., l.c.).  $\text{RhS}$  is insol. *aqua regia*, according to Debray (C. R. 97, 1333) (v. also Gibbs, J. pr. 91, 171; Lecoq de Boisbaudran, C. R. 96, 152).

**Rhodium sesquisulphide  $\text{Rh}_2\text{S}_3$  (Rhodo-rhodic sulphide).** Formed, by passing  $\text{H}_2\text{S}$  into solution of a Rh salt, as a black pp. according to Leidié (C. R. 106, 1076, 1533) the pp. is  $\text{Rh}_2\text{S}_3 \cdot 3\text{H}_2\text{S}$  (v. RHODIUM, HYDROSULPHIDE, p. 404), which becomes  $\text{Rh}_2\text{S}_3$  by heating for some time with water at  $100^\circ$ , in a closed vessel or in N. Leidié (l.c.) obtained  $\text{Rh}_2\text{S}_3$  in black crystalline tablets, by heating  $\text{RhCl}_3$  to  $360^\circ$  in a stream of  $\text{H}_2\text{S}$ ; according to L., this is the only method whereby pure  $\text{Rh}_2\text{S}_3$  can be prepared. Loses 8 p.c. S when heated in N to dull redness; all S expelled only in O-H flame (L., l.c.). Insol. alkali solutions; not acted on by  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ ,  $\text{BrAq}$ , or *aqua regia* (L., l.c.). Forms the double salt  $\text{Rh}_2\text{S}_3 \cdot 3\text{Na}_2\text{S}$ , by adding excess of conc.  $\text{Na}_2\text{SAq}$  to  $\text{Na}_2\text{RhCl}_6\text{Aq}$ ; decomposed by water, stable in presence of excess of alkali sulphide (Leidié, l.c.). M. M. P. M.

**RHODIUM-AMMONIUM COMPOUNDS.** (Rhodamines. Ammoniacal rhodium bases.) When a solution of Rh in *aqua regia* is evaporated with excess of  $\text{NH}_3\text{Aq}$  a compound

$\text{Rh}_2\text{Cl}_4 \cdot 10\text{NH}_3$  is obtained. By treating this body with moist  $\text{Ag}_2\text{O}$  and water in the cold  $\text{Rh}_2\text{Cl}_4 \cdot \text{O}_2\text{H}_2 \cdot 10\text{NH}_3$  is formed; if heat is used, the product is  $\text{Rh}_2\text{O}_3 \cdot \text{H}_2\text{O} \cdot 10\text{NH}_3$ . These compounds react as definite salts, which exchange their more negative radicles without losing Rh or  $\text{NH}_3$ . The classification of the rhodium-ammonium compounds generally adopted is similar to that used for the Cr and Co compounds (v. vol. ii. pp. 158 and 222). In the following general formulae M and X represent negative radicles, which may be the same or different

*Purpureo-rhodium series.*

*Roseo-rhodium series.*

*Luteo-rhodium series.*

The Rh compounds were investigated by Berzelius (*Lehrbuch*, 5th ed., 3, 956); Vauquelin (*A Ch.* 89, 167); Claus (*Beiträge zur Chemie der Platinmetalle*, Dorpat, 1854); and more recently by Jörgensen (*J pr.* [2] 27, 633; 34, 894; 44, 48).

#### I. PURPUREO-RHODIUM COMPOUNDS

$\text{M}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot \text{X}_2$ . Changed to roseo salts, without loss of  $\text{NH}_3$ , by boiling with alkali solution. The two atoms of radicle represented by M, are not removed by the ordinary reagents for removing this radicle from salts.

*Chloro-purpureo-series* (Jörgensen, l.c.).

*Chloropurpureorhodium chloride*

$\text{Cl}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot \text{Cl}_2$ . This salt is prepared by dissolving the alloy  $\text{RhZn}_2$  in *aqua regia*, evaporating to dryness, treating the residue with water, filtering, adding excess  $\text{NH}_3\text{Aq}$ , evaporating to dryness at  $100^\circ$ , heating with dil.  $\text{HClAq}$ , and filtering while hot; the insoluble salt is washed with dil.  $\text{HClAq}$ , dissolved in boiling water, and the hot solution is filtered into  $\text{HClAq}$  (1:1 by volume); the purpureo-chloride which separates is washed with dilute  $\text{HClAq}$ , and then with alcohol. Small lustrous yellow rhombic crystals; isomorphous with chloropurpureo-cobalt chloride (v. Topsøe, *J. pr.* [2] 27, 433; Keferstein, *A. Ch.* 99, 275). S.G. 2.079 at  $18^\circ$ . S. 56 cold water, considerably more sol. hot water. Sol. without decomposition in hot conc.  $\text{H}_2\text{SO}_4$ , also in boiling  $\text{NaOHAq}$ . Easily reduced to Rh, but not acted on by such oxidisers as *aqua regia* or  $\text{HClAq}$  and  $\text{KClO}_4$ . Heated in  $\text{CO}_2$  gives  $\text{Rh}_2\text{NH}_4\text{Cl}$ ,  $\text{NH}_3$ , and N; heated in H, gives Rh,  $\text{NH}_4\text{Cl}$ , and  $\text{NH}_3$ ; heated in  $\text{HCl}$  gas, gives Rh and  $\text{NH}_4\text{Cl}$ ; heated in Cl gives  $\text{RhCl}_3$  and  $\text{NH}_4\text{Cl}$ . Reacts with various substances to exchange  $\text{Cl}_2$  for equivalent quantities of other negative radicles. Combines with  $\text{PtCl}_4$  to form the *double salt*  $\text{Cl}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot \text{Cl}_2 \cdot 2\text{PtCl}_4$ .

*Chloropurpureorhodium hydroxide*

$\text{Cl}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot (\text{OH})_2$ . Known only in solution, which is obtained by rubbing the chlorochloride with a little water and moist  $\text{Ag}_2\text{O}$  for a few minutes, and filtering. Reacts strongly alkaline; gives salts by neutralisation with various acids. After warming, the solution contains roseo-chloride, and hydroxide  $\text{Rh}_2 \cdot 10\text{NH}_3 \cdot \text{Cl}_2(\text{OH})_2$ , along with  $\text{Rh}_2 \cdot 10\text{NH}_3 \cdot (\text{OH})_2$ , and gives a pp. with  $\text{AgNO}_3\text{Aq}$ .

The other salts of this series are the

*chloro-carbonate*  $\text{M}(\text{CO}_3)_2 \cdot 2\text{aq}$ , *chloro-nitrate*  $\text{M}(\text{NO}_3)_2$ , *silicofluoride*  $\text{M}(\text{SiF}_6)_2$ , and *chloro-sulphates*  $\text{M}(\text{SO}_4)_2 \cdot 2\text{aq}$  and  $\text{M}_2(\text{SO}_4)_3 \cdot 3\text{H}_2\text{SO}_4$ .  $\text{M} = \text{Cl}_2\text{Rh}_2 \cdot 10\text{NH}_3$ .

*Bromopurpureo-series* (Jörgensen, l.c.).

*Bromopurpureorhodium bromide*

$\text{Br}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot \text{Br}_2$ . Deep-yellow rhombic crystals; S.G. 2.65 at  $17.5^\circ$ ; scarcely sol. water. Prepared similarly to the chlorochloride, using  $\text{HBrAq}$  in place of  $\text{HClAq}$ ; also by dissolving the chlorochloride in 7 p.c. hot  $\text{NaOHAq}$ , digesting for about an hour at  $100^\circ$ , adding excess conc.  $\text{HBrAq}$ , washing the pp. which forms with dil.  $\text{HBrAq}$  and then with alcohol; also by saturating solution of roseo-hydroxide,  $\text{Rh}_2 \cdot 10\text{NH}_3 \cdot (\text{OH})_2$ , with dil.  $\text{HBrAq}$  and heating for some time at  $100^\circ$ . Forms a *double salt* with platinum bromide,  $\text{Br}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot \text{Br}_2 \cdot 2\text{PtBr}_2$ . The *bromo-nitrate*,  $\text{Br}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot (\text{NO}_3)_2$ , and *bromo-silicofluoride*,  $\text{Br}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot 2\text{SiF}_6$ , have been isolated.

*Iodopurpureo-series* (Jörgensen, l.c.).

*Iodopurpureorhodium iodide*  $\text{I}_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot \text{I}_2$ .

Prepared by heating the roseohydroxide with excess of  $\text{HIAq}$  for some time; then transforming the impure product into iodochloride by washing with water, then with alcohol, rubbing repeatedly with dil.  $\text{HClAq}$ , dissolving in hot water, and filtering into dil.  $\text{HClAq}$ . The iodo-chloride is then dissolved in hot water and poured into  $\text{KIAq}$ ; the pp. iodo-iodide is crystallised from hot water. Reddish-yellow, rhombic crystals; S.G. 3.11 at  $14.8^\circ$ ; very sl. sol. cold water. Forms a *double salt* with  $2\text{PtI}_4$ . The other salts of this series are the *iodo-chloride*  $\text{MCl}_2$ , *iodo-nitrate*  $\text{M}(\text{NO}_3)_2$ , *iodo-silicofluoride*  $\text{M}(\text{SiF}_6)_2$ , and *iodo-sulphate*  $\text{M}(\text{SO}_4)_2 \cdot 2\text{aq}$ .  $\text{M} = \text{I}_2\text{Rh}_2 \cdot 10\text{NH}_3$ .

*Nitratopurpureo-series* (Jörgensen, l.c.).

*Nitratopurpureorhodium nitrate*  $(\text{NO}_3)_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot (\text{NO}_3)_2$ .

Formed by heating the roseonitrate  $\text{Rh}_2 \cdot 10\text{NH}_3 \cdot (\text{NO}_3)_2$  to  $100^\circ$ ; also by adding an equal vol. conc.  $\text{HNO}_3\text{Aq}$  to an aqueous solution of the roseonitrate, and heating at  $100^\circ$ . Yellowish-white crystals; decomposes when heated. The other salts of this series are *nitrate-chloride*  $\text{MCl}_2$ , and *nitrate-dithionate*  $\text{M}(\text{S}_2\text{O}_8)_2 \cdot 2\text{aq}$ .  $\text{M} = (\text{NO}_3)_2\text{Rh}_2 \cdot 10\text{NH}_3$ .

*Nitritopurpureo-series* or *Xantho-*

*series* (Jörgensen, l.c. [2] 31, 49).

*Nitritopurpureorhodium nitrate*

$(\text{NO}_2)_2\text{Rh}_2 \cdot 10\text{NH}_3 \cdot (\text{NO}_2)_2$  (*Xanthorhodium nitrate*). 5 g. chlorochloride are heated with 50 c.c. water and 30 c.c.  $\text{NaOHAq}$  (7 p.c.) till dissolved; after cooling, 10 g. crystallised  $\text{NaNO}_2$  are added and then a slight excess of dil.  $\text{HNO}_3\text{Aq}$  (1 acid : 2 water). The powder which separates after a time is washed with dil.  $\text{HNO}_3\text{Aq}$ , and then with alcohol, and is crystallised from hot water. Octahedral crystals, isomorphous with corresponding Co salt. Insol. alcohol and dilute  $\text{HNO}_3\text{Aq}$ ; sl. sol. cold water; easily sol. hot water and conc.  $\text{HNO}_3\text{Aq}$ . No reaction with ordinary reagents for nitrites, e.g.  $\text{KIAq}$ ,  $\text{KMnO}_4\text{Aq}$ , &c. Conc.  $\text{H}_2\text{SO}_4$  does not evolve  $\text{NO}_2$ .

The other salts of this series are: *xanthobromide*  $\text{MBr}_2$ , *xanthochloride*  $\text{MCl}_2$ , *xanthodithionate*  $\text{M}(\text{S}_2\text{O}_8)_2 \cdot 2\text{aq}$ , *oxalate*  $\text{M}(\text{C}_2\text{O}_4)_2$ , *silicofluoride*  $\text{M}(\text{SiF}_6)_2$ , *sulphates*  $\text{M}(\text{SO}_4)_2$ , and  $\text{M}(\text{SO}_4)_3 \cdot 3\text{H}_2\text{SO}_4$ .  $\text{M} = (\text{NO}_2)_2\text{Rh}_2 \cdot 10\text{NH}_3$ .

## II. ROSEORHODIUM COMPOUNDS

$Rh_{10}NH_4X_{10} \cdot 2H_2O$ . All the atoms of the negative radicle in these salts react similarly; e.g.  $AgNO_3$  aq. ppt.  $6Cl$  from the chloride. Heated to  $100^\circ$   $2H_2O$  is given off, and purpleo- salts remain. These compounds are generally formed by treating the chloropurpleo- compounds with hot alkali solutions. Many are prepared from the hydroxide by the action of acids (Claus, L.; Jørgensen, Lc.).

*Roseorhodium hydroxide*  $Rh_{10}NH_4(OH)_{10}$ . Prepared by heating chloropurpleochloride with excess of moist  $Ag_2O$  and water for some days, filtering from  $AgCl$ , and evaporating *in vacuo*. A yellow deliquescent solid, with strongly alkaline reaction; ppts. metallic hydroxides from salts; decomposes  $NH_3$  salts, giving off  $NH_3$ . Neutralises acids, forming roseo- salts.

*Roseorhodium bromide*  $Rh_{10}NH_4Br_{10} \cdot 2H_2O$ . Ppd. by adding conc.  $HBr$  aq. to solution of the hydroxide; also by boiling chloropurpleochloride with  $NaOH$  aq. and then adding excess of conc.  $HBr$  aq. Pale-yellow crystals; changes to the purpleo- salt at  $100^\circ$ , or by crystallising from hot water. The other salts of this series are: carbonate  $M(CO_3)_2$  aq.; iodo- sulphate  $MI(SO_4)_2$ ; nitrate  $M(NO_3)_2$ , and the double salt  $M(NO_3)_2 \cdot PtCl_6$ ; phosphate  $M(HPO_4)_2$  aq., and the sodium pyrophosphate  $M(NaP_2O_7)_2$  23aq.; sulphate  $M(SO_4)_2$  3aq., and the double salt  $M(SO_4)_2 \cdot PtCl_6$ .

III. LUTEORHODIUM COMPOUNDS  $Rh_{12}NH_4X_{12}$ . These salts are very stable. Their colours are the same as those of corresponding roseo- salts. The chloride can be prepared by heating the chloropurpleochloride with conc.  $NH_3$  aq.; most of the other salts are obtained from the chloride (Jørgensen, J. pr. [2] 44, 48, 63). The negative radicles are all acted on similarly by reagents.

*Luteorhodium chloride*  $Rh_{12}NH_4Cl_{12}$ . Prepared by heating chloropurpleochloride with c. 30 times its weight  $NH_3$  aq. (25 p.c.  $NH_3$ ) for several days at  $100^\circ$ – $102^\circ$ , dissolving in hot water, and ppg. by conc.  $HCl$  aq. S. c. 12 at  $8^\circ$ . Not changed to chloropurpleochloride by digestion with  $HCl$  aq. at  $100^\circ$ . Forms the double salt  $Rh_{12}NH_4Cl_{12} \cdot 3PtCl_6$  6aq. The other salts of this series described by Jørgensen are: bromide  $MBr$ , nitrates  $M(NO_3)_2$  and  $M(NO_3)_2 \cdot HNO_3$ , phosphate  $M(PO_4)_2$  8aq. and sodium luteo-pyrophosphate  $M(NaP_2O_7)_2$  23aq., and sulphate  $M(SO_4)_2$  6aq.

*Rhodium-pyridine compounds*. Compounds of  $Rh$  with pyridine,  $C_5H_5N$ , and negative radicles have been prepared by Jørgensen (J. pr. [2] 27, 433). The compounds examined contain  $8C_5H_5N$ , and correspond with the chromtetrammonium series of ammoniacal compounds (vol. ii. p. 159), and with the octamine series of ammoniacal Co compounds (vol. ii. p. 225). The composition of these pyridine compounds is represented by the formula  $M.Rh_4(C_5H_5N)_8X_4$ , where  $M = Cl$  and  $X = Br, Cl, OH, NO_3$ , and  $SO_4$ . The salts resemble the  $NH_4$  compounds generally. The chloride ( $X = Cl$ ) is prepared similarly to chloropurpleorhodium chloride, using pyridine in place of ammonia; the other salts are prepared from the chloride by the action of acids.  $AgNO_3$  aq. ppts. one-third of the halogen only from the chloride and bromide. M. M. P. M.

## RHODIZONIC ACID v. DI-OXY-DIQUINOL.

**RHÆADINE**  $C_{12}H_7NO_4$ . [232°]. S. (80 p.c. alcohol)  $0.9$ . S. (ether)  $0.8$  at  $18^\circ$ . An alkaloid occurring in all parts of the red poppy *Papaver Rhæas*, and in the white seed capsules of the white poppy *Papaver somniferum* (Hesse, A. 140, 145; 149, 35; 153, 47). Small white prisms, nearly insol. water, alcohol, and ether. May be sublimed. Tasteless, and not poisonous. Its solution in very weak  $HCl$  is colourless, but in conc.  $HCl$  aq. and in  $H_2SO_4$  it forms purple solutions, the base being partially decomposed. The colourless solution is ppd. by tannin and by  $HgCl_2$ .

Salts.— $B'H_2PtCl_6$  2aq.: yellow amorphous pp.— $B'HI$  2aq.: mass of minute prisms.

**Rhæogenine**  $C_{12}H_{11}NO_4$ . [223°]. S. (80 p.c. alcohol)  $0.7$ . S. (ether)  $0.6$ . Formed by boiling rhæadine with dilute  $H_2SO_4$ . Small crystals (from alcohol), sl. sol. ether, alcohol, and water, v. sol. dilute acids. Its alcoholic solution turns litmus blue. Cannot be sublimed. Not coloured by acids. Its salts taste bitter.— $B'H_2PtCl_6$ — $B'HI$ : short prisms, m. sol. hot water.

RIBONIC ACID  $C_5H_8O_6$ , i.e.

$CH_2(OH).CH(OH).CH(OH).CH(OH).CO_2H$ .

*Tetra-oxy-valeric acid*. Formed by heating  $CH_2(OH).CH(OH).CH(OH).CH(OH).CO_2H$ , arabonic acid, with pyridine in a closed vessel at  $130^\circ$  (E. Fischer a. Piloty, B. 24, 4216). When set free from its salts it changes into the lactone.— $HgA_2$ : needles.— $CdA_2$ .  $[a]_D = 0.6^\circ$ . Needles.

*Lactone*  $C_5H_6O_5$ . [72°–76°].  $[a]_D = -18^\circ$ . Colourless prisms, v. s. sol. water and alcohol, v. sl. sol. ether. Converted by heating with pyridine and water at  $135^\circ$  into arabonic acid.  $HNO_3$  yields tri-oxy-glutaric acid. Phenyl hydrazine forms  $C_9H_8O_5(N_2H_5Ph)$  [164°].

**RIBOSE**  $*C_5H_{10}O_5$ . Formed by reducing the lactone of ribonic acid with sodium-amalgam (Fischer a. Piloty, B. 24, 4220). Colourless syrup. Yields a phenyl-hydrazide [155°] and a p-bromo-phenyl-hydrazide  $C_{11}H_{10}O_5N_2Br$  [165°].

RICINELAIDIC ACID  $C_{18}H_{34}O_8$ . [58°].

Formed by the action of nitrous acid on ricinoleic acid (Boudet, A. 4, 16; Playfair, A. 60, 322; Bouis, A. Ch. [3] 44, 82; Ulrich, Bl. [2] 9, 225). Got also by saponifying ricinelaïdin. White silky needles, v. sol. alcohol and ether. Reddens litmus. Yields n-heptoic acid on oxidation with  $HNO_3$  (Krafft, B. 21, 2735). Alkaline  $KMnO_4$  yields two tri-oxy-stearic acids [120°] and [116°] (Grüssner a. Hazura, M. 10, 196; Mangold, M. 13, 326). Forms oily  $C_{18}H_{34}BrO_8$ , converted by  $KOH$  aq. in the cold into  $C_{18}H_{32}BrO_8$ , whence alcoholic potash forms an acid melting at  $71^\circ$ .

Salts.— $BaA'$ : unctuous powder.— $AgA'$ : white powder, sol.  $NH_4$  aq.

*Ethyl ether EA'*. [16°]. Crystalline.

*Amide*  $C_{18}H_{35}NO_8$ . [93°] (Rowney, Chem. Gaz. 1855, 361).

## Reference.—BROMO-RICINELAIDIC ACID.

**RICINELAIDIN**. [45°] (Bouis); [66°] (Boudet). Formed by the action of nitrous fumes on castor oil. Solid, v. sol. alcohol and ether. Split up by boiling  $KOH$  aq. into glycerin and potassium ricinolaïdate. Yields heptoic aldehyde (enanthal) on dry distillation (Bertagnini, A. 85, 282). Yields octyl alcohol and potassium sebacate on distillation with potash (Bouis).

**RICINIC ACID**  $C_{18}H_{34}O_2$ , *i.e.*  $C_{17}H_{32}(OH).CO_2H$ . [81°]. (252° at 15 mm.). Formed by distilling barium ricinoleate *in vacuo* (Krafft, *B.* 21, 2736). Plates (from dilute alcohol). Yields, on oxidation by  $HNO_3$ , *n*-heptioic acid and an acid [c. 103°] not volatile with steam. Converted by HCl into diricinic acid  $C_{17}H_{32}(OH).CO.O.C_1H_{11}CO_2H$ , tricinic acid  $C_{17}H_{32}(OH).CO.O.C_1H_{11}CO.O.C_1H_{11}CO_2H$ , and polyricinic acids. Sulphuric acid forms these acids, as well as  $SO_3H.O.C_1H_{11}CO_2H$ ,  $SO_3H.O.C_1H_{11}CO.O.C_1H_{11}CO_2H$ , &c.  $H_2SO_4$  acting on castor oil forms the compound  $SO_3 \begin{smallmatrix} O.C_1H_{11}CO_2 \\ O.C_1H_{11}CO_2 \end{smallmatrix} C_1H_{11}CO_2H$  and the above acids, constituting Turkey red oil. The polyricinic acids are converted by boiling KOHAq but not by  $Na_2CO_3$  into ricinic acid. Hot water decomposes the polyricino-sulphuric acids into  $H_2SO_4$  and polyricinic acids (Juillard, *Bl.* [3] 6, 688).

**RICININE**. An alkaloid occurring, according to Tason (*C. J.* 17, 195; *C. N.* 22, 229; cf. Werner, *C. N.* 22, 203), in the seeds of the castor oil plant (*Ricinus communis*). Rectangular prisms or laminæ, insol. water, nearly insol. ether, sol. alcohol.

**RICINISOLIC ACID** *v.* TRI-OXY-STEARIC ACID.

**RICINOLEIC ACID**  $C_{18}H_{34}O_3$ , *i.e.*  $CH_2[CH_2]_7CH(OH).CH:CH[CH_2]_7CO_2H$  (?). [17°]. Occurs as glyceride in castor oil (Bussy a. Lecanu, *J. Ph.* 13, 70; Saalmlüller, *A.* 64, 108; Svanberg a. Grömodin, *J. pr.* 45, 431; Bouis, *A. Ch.* [3] 44, 103; 48, 99; Petersen, *A.* 118, 69). Prepared by saponification of castor oil by KOH or HCl and purified by means of its Ca or Ba salt (Claus, *B.* 9, 1916; Krafft, *B.* 21, 2731). Crystalline mass, miscible with alcohol and ether. Its alcoholic solution is alkaline in reaction. Does not absorb oxygen from the air. Yields  $C_{18}H_{32}O_4$ . Yields polymerides when heated with water in closed vessels (Seheurer-Kestner, *C. R.* 113, 201).

**Reactions**.—1. Oxidised by  $HNO_3$  to azelaic acid  $C_9H_{16}O_4$ , oxalic acid, and heptioic acid.—2. Alkaline  $KMnO_4$  forms two isomeric tri-oxy-stearic acids (Dieff, *J. pr.* [2] 39, 345; *B.* 20, 1211; Hazura a. Grüssner, *M.* 8, 475; Mangold, *M.* 13, 826).—3. Nitrous acid forms ricinelaic acid.—4. Yields methyl hexyl ketone (173°) and an acid  $C_{18}H_{32}O_3$  [81°] on distillation of the Ba salt.—5. The Na salt on distillation with NaOH yields methyl hexyl ketone, *sec*-octyl alcohol and sodium sebacate  $Na_2C_{10}H_{19}O_4$ .—6. Bromine forms oily  $C_{18}H_{32}Br_2O_3$ , converted by alcoholic potash into  $C_{18}H_{32}BrO_3$ , whence Br forms oily  $C_{18}H_{32}Br_2O_3$ , converted by alcoholic potash at 120° into ricinostearolic acid  $C_{18}H_{32}O_4$ , which combines with bromine forming unstable oily  $C_{18}H_{32}Br_2O_4$ .—7.  $PCl_5$  forms  $C_{18}H_{32}Cl_2O_4$ .—8. HI and P give  $C_{18}H_{32}IO_4$ .

**Salts**.— $BaA_2$ : soft scales (from alcohol), al. sol. water.— $SrA_2$ : small grains (from alcohol).— $CaA_2$  (dried at 100°). [80°].— $MgA_2$ : slender needles, v. sol. alcohol.— $PbA_2$ . [100°]. Crystalline mass, v. sol. ether.— $ZnA_2$ .— $AgA$ : curdy pp.

*Ethyl ether* Et.A'. Oil.

**Amide**  $C_{18}H_{33}CONH_2$ . [66°]. Nodules (from alcohol).

**References**.—Bromo- and Oxy-ricinolol<sup>10</sup> acid.

**RICINOLIC ACID** *v.* TRI-OXY-STEARIC ACID.

**RICINOSTEAROLIC ACID**  $C_{18}H_{32}O_7$ . [51°]. Formed by heating the dibromide of ricinoleic acid with alcoholic potash (Ulrich, *Z.* 1867, 547). Groups of needles (from alcohol), v. sol. ether. Volatile.— $BaA_2$ : plates (from alcohol) [135°].— $AgA$ : granular pp.

**RICINOSTEAROXYLIC ACID**  $C_{18}H_{32}O_8$ . [78°]. Formed by heating ricinostearolic acid with moist  $Ag_2O$  (Ulrich, *Z.* 1867, 550). Dendritic groups of needles (from alcohol), v. sol. ether.— $BaA_2$ .— $AgA$ : granular pp. decomposed by hot alcohol.

**ROBININ**  $C_{20}H_{30}O_{16}$ . [195°]. Occurs in the blossoms of the acacia (*Robinia pseudacacia*) (Zwenger a. Dronke, *A. Suppl.* 1, 257). Thin yellow needles (containing 54 aq). Neutral in reaction. Tasteless, sl. sol. cold water and alcohol, insol. ether. Sol. alkalis, forming yellow solutions. The ammoniacal solution turns brown in air.  $FeCl_3$  gives a brown colour. Its alcoholic solution is ppd. by lead subacetate. Reduces hot Fehling's solution.  $HNO_3$  forms oxalic and picric acids. Split up by boiling dilute acids into quercetin and a sugar.

**ROCCELLIC ACID**  $C_{18}H_{32}O_6$ . [132°]. S. (boiling alcohol of S.G. 819) 55. Occurs in various species of *Rocella* (Heeren, *S. J.* 59, 346; Liebig, *P.* 21, 31; Schunck, *A.* 61, 64; Hesse, *A.* 117, 332). Four-sided prisms, insol. water, v. sol. alcohol and ether, sl. sol. warm benzene. Sol.  $Na_2CO_3$  and borax.

**Salts**.— $BaA''$  (dried at 100°).— $CaA''$  aq: amorphous pp.— $PbA''_2(OH)_2$  2aq: white powder.— $AgA''$ : amorphous pp.

*Ethyl ether* Et.A'. Oil.

**Anhydride**  $C_{18}H_{30}O_5$ . Got by heating the acid above 220°. Oil, v. sol. hot alcohol and ether.

**Anilide**  $C_{18}H_{30}O_5(NHPh)_2$ . [55°]. Got by heating the acid with aniline at 190°. Colourless laminæ (from alcohol), insol. water,  $NH_4Aq$ , and  $HClAq$ .

**ROCCELLININ**  $C_{18}H_{30}O_6$ . Occurs in *Rocella tinctoria* (Stenhouse, *A.* 68, 69). Silky needles (from alcohol), nearly insol. cold alcohol and ether. Its solutions in alkalis are not coloured by air. Not decomposed by boiling KOHAq. Does not pp. metallic salts.

**ROCHELLE SALTS**. *Potassium-sodium tartrate*; *v.* TARTRATES.

**ROSANILINE**  $C_{20}H_{16}N_4O$  *i.e.*

$[(4:1)C_6H_4(NH_2)_2.C(OH).C_6H_4.Me(NH_2)] [1:3:4]$ .

**Tri-amido-di-phenyl-tolyl-carbinol**. Formed by oxidation of a mixture of aniline, *o*-toluidine, and *p*-toluidine (Hofmann, *J. pr.* 77, 190; 87, 226; *Pr.* 12, 2; Mühlhäuser, *D. P. J.* 266, 455, 503, 547).  $SnCl_4$ ,  $As_2O_3$ ,  $HNO_3$ ,  $Hg(NO_3)_2$ ,  $FeCl_3$ , and nitrobenzene may be used as oxidising agents. For the production of a red colouring matter it is essential that there should be present a base with methyl in the *p*-position to amidogen (*p*-toluidine, 1,3,4-xylydine, or mesidine), and also a base with H in the *p*-position to amidogen (*e.g.* aniline, *o*-toluidine, or 1,3,2-xylydine) (Rosenstiehl, *C. R.* 82, 415; 94, 1319; 95, 238; 98, 433; *A. Ch.* [6] 2, 360). When nitro-benzene is used as oxidising agent it appears to be itself reduced to benzene and

nitrogen, and not to take part in the formation of rosaniline. Thus, when chloro-nitro-benzene, nitro-aniline, or di-nitro-benzene is used, a substituted rosaniline (e.g. chloro-rosaniline) is not formed (Lange, *B.* 18, 1918). Colourless needles or plates, obtained by ppg. a solution of one of its salts with  $\text{NH}_4\text{Aq}$  and recrystallising. Nearly insol. water, sl. sol.  $\text{NH}_4\text{Aq}$ , m. sol. alcohol, insol. ether. Turns red in air. Dyes silk and wool in acid, neutral, and even in slightly ammoniacal solutions.

**Reactions.**—1. Reduced by ammonium sulphide or powdered zinc to tri-amido-di-phenyl-tolyl-methane (leucaniline) (Hofmann, *Pr.* 12, 2).—2. Yields alkyl derivatives on heating with alkyl iodides and phenyl derivatives on heating a salt with aniline (Hofmann, *Pr.* 13, 9). Benzyl chloride, methyl iodide, and  $\text{MeOH}$  form  $\text{C}_{20}\text{H}_{18}(\text{C}_6\text{H}_5)_3\text{N}_3\text{Me}$ , crystallising in lustrous green needles (Hofmann, *B.* 6, 263).—3. The hydrochloride, heated with water at  $235^\circ$ , forms  $\text{NH}_4\text{Cl}$ , phenol, red crystals of  $\text{C}_{20}\text{H}_{18}\text{N}_3\text{O}_2$  [ $176^\circ$ ], and colourless crystals, which turn red in air and then crystallise from alcohol in red needles  $\text{C}_{20}\text{H}_{18}\text{NO}_2$  (Liebemann, *B.* 5, 144; 6, 951).—4. The hydrochloride, heated with dilute  $\text{HClAq}$  at  $240^\circ$ , yields aniline and toluidine (*L.*).—5. Water at  $270^\circ$  forms di-oxy-benzophenone, di-amido-phenyl-tolyl-ketone, oxy-amido-phenyl-tolyl-ketone, phenol, and  $\text{NH}_3$  (Liebemann, *B.* 6, 951; 11, 1435; 16, 1927).—6. Potassium cyanide added to rosaniline acetate in alcohol yields  $\text{C}_{20}\text{H}_{18}\text{N}_3$ , a white crystalline powder, sol.  $\text{HClAq}$ , and reppd. by  $\text{NH}_4\text{Aq}$ . It separates from alcohol in monoclinic crystals. It forms crystalline salts.—7. A solution of a rosaniline salt is decolourised by  $\text{SO}_2$ , and the solution is turned red, and afterwards violet, by aldehydes, and gradually deposits copper-coloured scales of alkylidene derivatives (Schiff, *B.* [2] 7, 518). Thus  $\alpha$ -naphthol forms  $\text{C}_{20}\text{H}_{18}\text{CH}(\text{C}_6\text{H}_5)_3\text{N}_3$ , which yields  $\text{B}''\text{HAsO}_2$  and  $\text{B}'\text{H}_2\text{PtCl}_6$ .—8.  $\alpha$ -Naphthol reacts with rosaniline acetate in the cold, forming  $(\text{C}_6\text{H}_5)_3(\text{C}_{20}\text{H}_{18}\text{N}_3)_2$  (Schiff, *B.* [2] 5, 291).—9. By exhaustive chlorination it yields  $\text{CCl}_4$  and per-chloro-benzene (Merz a. Weith, *B.* 16, 2876).—10. Boiling  $\text{Ac}_2\text{O}$  yields a tetra-acetyl derivative as a reddish amorphous powder. The same body is got by treating tri-acetyl-tri-amido-di-phenyl-tolyl-methane with  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{HOAc}$  (Renouf, *B.* 16, 1303). A mono-acetyl derivative  $\text{C}_{20}\text{H}_{17}\text{AcN}_3$ , got by heating rosaniline hydrochloride with acetamide, is reddish-brown and yields dark-blue  $\text{B}'\text{HCl}$  with metallic lustre (Beckerhinn, *J.* 1870, 768).—11. May be sulphonated by  $\text{H}_2\text{SO}_4$  containing  $\text{SO}_2$  at  $130^\circ$  (Schoop, *Chem. Zeit.* 11, 572).—12. By diazotisation followed by reduction with tin and  $\text{HCl}$  in the cold it is converted into 'rosydrazide,' the hydrochloride of which forms green crystals, and dyes cotton brownish-red (Ziegler, *B.* 20, 1557).—13.  $\text{Br}$  forms a tetra-bromo-rosaniline (?) crystallising from benzene in prisms (Caro a. Graebe, *A.* 179, 203).—14. Aldehyde forms a blue product which is converted by  $\text{Na}_2\text{S}_2\text{O}_8$  into aldehyde green  $\text{C}_{20}\text{H}_{18}\text{N}_3\text{S}_2\text{O}_8$ , an amorphous green mass, sol. alcohol and ppg. by ether (Cherpin; Usébe, *J. pr.* 92, 337; Hofmann, *B.* 3, 761; Gattermann, *B.* 22, 227).

**Salts.**—These are derived from the anhydrous base  $\text{C}_{20}\text{H}_{18}\text{N}_3\text{O}(\text{C}_6\text{H}_5)_3\text{N}_3$ — $\text{C}_{20}\text{H}_{18}\text{N}_3\text{HCl}$ .

Red crystals with green lustre. Insol. ether, sl. sol. water, m. sol. alcohol. Its solution in water or alcohol is crimson. Dyes wool and silk magenta. The absorption-spectrum has been studied by Hartley (*C. J.* 51, 169).— $\text{C}_{20}\text{H}_{18}\text{N}_3\text{HCl}$ . Ppd. by conc.  $\text{HClAq}$ . Yellowish-brown needles, more sol. alcohol and water than  $\text{B}''\text{HCl}$ .—Decomposed by much water, forming  $\text{B}''\text{HCl}$ .— $\text{C}_{20}\text{H}_{18}\text{N}_3\text{HCl}$  or  $(\text{C}_6\text{H}_5)_3\text{N}_3\text{HCl} \cdot \text{CCl}(\text{C}_6\text{H}_5)_2$ . Got by passing dry  $\text{HCl}$  into rosaniline powder (Rosenstiehl, *Bl.* [3] 9, 122). Reddish-brown and hygroscopic, forming a magenta solution. Fumes in air, giving off  $\text{HCl}$ . After keeping it is not completely soluble.— $\text{C}_{20}\text{H}_{18}\text{N}_3\text{HBr}$ . Resembles the preceding salt.— $\text{C}_{20}\text{H}_{18}\text{N}_3\text{HOAc}$ . Large crystals with green metallic lustre; v. sol. water and alcohol.— $(\text{C}_{20}\text{H}_{18}\text{N}_3)_2\text{H}_2\text{PtCl}_6$ . Amorphous.— $(\text{C}_{20}\text{H}_{18}\text{N}_3)_2\text{H}_2\text{PtCl}_6 \cdot \text{C}_{20}\text{H}_{18}\text{N}_3\text{HBr}$ . Sl. sol. water.— $\text{C}_{20}\text{H}_{18}\text{N}_3\text{HI}$ . Green needles, v. sol. water.— $\text{C}_{20}\text{H}_{18}\text{N}_3\text{HNO}_3$ ; small crystals.— $(\text{C}_{20}\text{H}_{18}\text{N}_3)_2\text{H}_2\text{SO}_4$  (Dried at  $130^\circ$ ). Crystals with green lustre. Does not form an alum with  $\text{Al}_2(\text{SO}_4)_3$  (Wood, *C. N.* 38, 1).— $\text{C}_{20}\text{H}_{18}\text{N}_3\text{C}_6\text{H}_5\text{N}_3\text{O}$ . Red needles, very slightly sol. water.— $(\text{C}_{20}\text{H}_{18}\text{N}_3)_2\text{H}_2\text{C}_6\text{O}_4$ .—Tannate: ppg. by adding tannin to an aqueous solution of a salt of rosaniline. Red mass, insol. water, sol. alcohol and  $\text{HOAc}$  (*E.* Kopp, *J.* 1862, 694).—Aurinate: Got by heating equivalent quantities of rosaniline and aurin with alcohol (Dale a. Schorlemmer, *C. J.* 43, 186). Hexagonal crystals with green lustre (Dyson, *C. J.* 43, 471). More sol. alcohol than either constituent. Dyes silk magenta.—Phenate  $\text{C}_{20}\text{H}_{18}\text{N}_3\text{C}_6\text{H}_5\text{O}$ . Got by heating rosaniline with phenol, dissolving in alcohol, and ppg. with water (Dyson, *C. J.* 43, 470).

**Para-rosaniline**  $\text{C}_{19}\text{H}_{17}\text{N}_3\text{O}$  i.e.

$[(1:4)\text{C}_6\text{H}_4(\text{NH}_2)_2]\text{COH}$ . Tri-amido-tri-phenyl-carbinol.

**Formation.**—1. From tri-nitro-tri-phenyl-methane by oxidation by  $\text{CrO}_3$  and  $\text{HOAc}$  followed by reduction of the resulting tri-nitro-tri-phenyl-carbinol with zinc-dust and  $\text{HOAc}$  (*E.* a. O. Fischer, *B.* 11, 195, 473, 612, 1079, 1598; *A.* 194, 242).—2. By heating a mixture of aniline and *p*-toluidine with arsenic acid (Rosenstiehl, *A. Ch.* [5] 8, 192); formed therefore in the preparation of rosaniline (Graebe, *B.* 12, 2241).—3. By heating *p*-nitro-di-amido-tri-phenyl-methane with  $\text{FeCl}_2$  at  $170^\circ$  (O. Fischer, *B.* 15, 678).—4. By heating *p*-nitro-benzylidene bromide with aniline (Zimmermann a. Müller, *B.* 17, 2936).—5. By heating aurin with  $\text{NH}_4\text{Aq}$  at  $180^\circ$  (Dale a. Schorlemmer, *B.* 10, 1016).—6. By heating di-amido-di-phenyl-methane (from aniline and formic aldehyde) with aniline, aniline hydrochloride, and nitro-benzene or arsenic acid.

**Properties.**—Crystalline plates. Nearly colourless; sl. sol. water; absorbs  $\text{CO}_2$  from air. Its solution in conc.  $\text{HClAq}$  is coloured grass-green by a crystal of  $\text{KClO}_4$ .

**Reactions.**—1. Yields *o*-toluidine and di-amido-benzophenone [ $237^\circ$ ] on boiling with  $\text{HClAq}$  for a long time (Wicnelhaus, *B.* 19, 110).—2.  $\text{HIAq}$  at  $190^\circ$  forms aniline and *p*-toluidine.—3. Nitrous acid forms the tri-diazo-derivative, which on boiling is converted into aurin.—4. Reduced by zinc-dust and  $\text{HClAq}$  to tri-amido-tri-phenyl-methane.—5.  $\text{KCy}$  added to its hydrochloride in presence of alcohol forms 'hydro-

cyanpararosaniline'  $C_{16}H_{11}N_3.HCN$ , crystallising from hot alcohol in colourless prisms, forming  $BH_4Cl$ , 2aq.—6. Pararosaniline (5 g.) is slowly converted by conc.  $HClAq$  (55 g.), water (65 g.), and aldehyde (22 g.) in the cold into aldehyde-blue, a dark-blue hygroscopic powder, ppd. by adding  $NaCl$  to the product after dilution with water (Gattermann, *B.* 22, 227). Aldehyde blue yields, on distillation, a solid base  $C_{16}H_{11}N_3$ .

Salt.— $C_{16}H_{11}N_3.Cl$ . S. 24 at  $9^\circ$ .

Tri-methyl-rosaniline v. TRI-METHYL-TRI-AMIDO-DI-PHENYL-TOLYL-CARBINOL.

Hexa-methyl-pararosaniline v. HEXA-METHYL-TRI-AMIDO-TRI-PHENYL-CARBINOL.

Phenyl-rosanilines v. HEXA-PHENYL-TRI-AMIDO-TRI-PHENYL-CARBINOL and TRI-PHENYL-TRI-AMIDO-DI-PHENYL-TOLYL-CARBINOL.

ROSEINE. A name for salts of ROSANILINE.

ROSEMARY OIL. S.G.  $1.5-1.905$ .  $n_D^{20} = +42'$  to  $+9^\circ 48'$  in 100 mm. (Schimmel, *Ph.* [3] 21, 940; 22, 328). Obtained by steam-distillation from *Rosmarinus officinalis* (Kane, *Trans. Irish Acad.* 18, 135; Lallemand, *A.* 114, 197; *A. Ch.* [3] 57, 404; Gladstone, *J.* 1863, 549; Montgolfier, *Bl.* 1876, 18; Bruylants, *J. Ph.* [4] 29, 508). Contains a terpene (165%), dextrorotatory camphor, borneol, and cineol  $C_{15}H_{26}O$  ( $176^\circ-179^\circ$ ) (Weber, *A.* 238, 89). The cineol forms a hydrochloride ( $C_{15}H_{26}O.HCl$ ), a tetra-bromide [ $124^\circ$ ], and the iodide  $C_{15}H_{25}I_2$  [ $79^\circ$ ].

ROSE OIL. Obtained by steam-distillation from rose leaves. Contains a stearoptene  $C_{16}H_{31}$  [ $34^\circ$ ] ( $865^\circ$ ) which is not attacked by chromic acid mixture and appears to be a paraffin (Markownikoff, *B.* 23, 3191; *J. pr.* [2] 48, 311; cf. Blanchet, *A.* 7, 154; Gladstone & Dale, *C. J.* 17, 1; Salkülsinski, *N. R. P.* 24, 129; Bauer, *D. P. J.* 204, 253; Flückiger, *Z.* [2] 6, 126; Panajotoff, *B.* 24, 2700; Eckart, *B.* 24, 4205). Rose oil also contains rhodinol (*q.v.*). Bulgarian oil of roses contains roseol  $C_{16}H_{32}O$  ( $225^\circ$  cor.), which is oxidised by  $KMnO_4$  to  $C_{16}H_{30}(OH)$ , ( $240^\circ$ ) S.G.  $\frac{2}{3} 1.0445$ ;  $\frac{2}{3} 1.0343$ ; and is reduced by  $HI$  to  $C_{16}H_{34}$  ( $159^\circ$ ) S.G.  $\frac{2}{3} .7700$ ;  $\frac{2}{3} .7554$  (Ladenburg, *J. pr.* [2] 48, 293).

ROSEOCOBALT SALTS v. COBALTAMINES, vol. ii. p. 226.

ROSEOCHROMIUM SALTS v. CHROM-AMMONIUM SALTS, vol. ii. p. 160.

ROSEORHODIUM SALTS v. RHODIUM-AMMONIUM COMPOUNDS, this vol. p. 407.

ROSEWOOD OIL. The oil got by steam-distillation from the wood of *Convolvulus scoparius* contains a terpene  $C_{16}H_{32}$  ( $249^\circ$ ) (Gladstone & Dale). Rosewood also contains a black resin  $C_{22}H_{34}O_6$  [ $95^\circ$ ] S.G.  $1.266$ , which is insol. water, sol. alcohol, and gives a blood-red colour with  $H_2SO_4$  (Terreil & Wolf, *Bl.* [2] 83, 435).

ROSINDOLES. Red colouring matters, greatly resembling rosaniline, formed by heating indoles with  $BzCl$ , and by oxidation of benzylidene derivatives of indoles (E. Fischer & Wagner, *B.* 20, 815). Thus methyl-ketole yields dimethyl-rosindole,  $C_{22}H_{28}N_2$ , which may possibly be  $C_6H_5(C_6H_5NH)_2$ .

ROSINDONE  $C_6H_5 \langle \text{C} \equiv \text{N} \rangle \text{CO.CH:C} \cdot \text{NPh} \rangle C_6H_5$ .

Rosindulone. [ $262^\circ$ ]. Formed by heating rosin-dulone with conc.  $HClAq$  at  $170^\circ$  under pressure (Fischer & Hepp, *A.* 256, 238; 262, 244).

Formed also from oxy-naphthoquinone and phenyl-o-phenylene-diamine (Kehrmann, *J. pr.* [2] 43, 269; *B.* 24, 586). Red hexagonal tables, insol. hot water, m. sol. boiling alcohol, forming a scarlet solution with brick-red fluorescence. Reduced to naphthophenazine by distilling in a current of  $H$  over zinc-dust. Converted by *p*-toluidine at  $130^\circ$  into *p*-tolyl-rosinduline. Oxidised by  $CrO_3$  to rosindonic acid  $C_{22}H_{15}N_3O_4$ , which crystallises in colourless needles, sl. sol. alcohol, insol. water, v. sol. ether.

ROSINDULINE  $C_{22}H_{15}N_3$ , i.e.

$C_6H_5 \langle \text{C} \equiv \text{N} \rangle \text{CH:C} \cdot \text{NPh} \rangle C_6H_5$ . [199].

Formed by heating benzene-azo-(a)-naphthyl-amine with aniline and alcohol at  $165^\circ$  under pressure (Fischer & Hepp, *A.* 256, 236). Formed also by heating phenyl-o-phenylene-diamine with oxy-naphthoquinone imide,  $HOAc$ , and alcohol at  $100^\circ$  (Kehrmann, *J. pr.* [2] 43, 269; *B.* 24, 587). Reddish-brown plates, v. sol. alcohol and ether, insol. water. Conc.  $H_2SO_4$  forms a green solution, becoming red on dilution. The alcoholic solutions exhibit reddish-yellow fluorescence.— $BHCl$  3:1 aq.: red needles.

Rosinduline. This name has also been given to the phenyl derivative of the preceding body (v. vol. iii. p. 9).

ROSOLIC ACID v. TRI-OXY-DI-PHENYL-TOLYL-CARBINOL and TRI-OXY-TRI-PHENYL-CARBINOL.

ROTLERIN  $C_{11}H_{10}O_2$ ? [ $200^\circ$ ]. A yellow substance occurring in the fruit of *Rottlera tinctoria*, which grows in India (Anderson, *N. Ed. P. J.* [2] 1, 300; Jawein, *B.* 20, 182). It is identical with Mallotoxin (*q.v.*).

RUBAZONIC ACID  $C_{28}H_{18}N_4O_4$ . Formed by oxidation of oxy-amido-phenyl-methyl-pyrazole (Knorr, *A.* 238, 137). Got also by boiling pyrazole-blue with  $NH_4Aq$ . Prepared from the phenyl-hydrazide of oxy-phenyl-methyl-pyrazole by reduction with zinc-dust and  $HOAc$ , followed by oxidation with  $FeCl_3$  (Buchka & Sprague, *B.* 22, 2551). Insol. water and dilute acids, v. sol. ether and benzene. Its solutions in alkalis are deep violet, but on boiling become yellow.

RUBERYTHRIC ACID  $C_{28}H_{20}O_4$ , i.e.  $C_{11}H_7O_2(OH).O.C_6H_4.O_2(OH)$ . Rubianic acid. [ $260^\circ$ ]. Obtained from madder-root by extracting with boiling absolute alcohol (Rochleder, *A.* 80, 321; 82, 205; Schunck, *A.* 66, 176; Liebermann & Bergami, *B.* 20, 2241). Lemon-yellow needles, v. sol. hot water, v. sl. sol. alcohol, insol. ether. Its alcoholic solution is yellow. Alkalis form blood-red solutions. It does not ferment with yeast. Boiling dilute acids split it up into alizarin and sugar.  $Ac_2O$  and  $NaOAc$  yield  $C_{28}H_{20}Ac_4O_4$ , crystallising in yellow needles [ $230^\circ$ ].— $C_{28}H_{20}KO_4 \cdot BaA_2aq$ .

RUBIAN  $C_{28}H_{20}O_4$ . A glucoside in madder root, split up by acids, alkalis, or the madder-ferment (erythrozym) into glucose, alizarin, and other bodies (Schunck, *P. M.* [4] 12, 200, 270; *J. pr.* 59, 465). Amorphous resin, v. sol. water, m. sol. alcohol, insol. ether. Its solutions are very bitter. Yields ruberythric acid on treatment with baryta. It is probably a mixture of ruberythric acid and other bodies.

RUBIANIC ACID v. RUBERYTHRIC ACID.

RUBIDINE. A general name for homologues of pyridine of the formula  $C_{11}H_8N$ , e.g. DI-METHYL-ISOBUTYL-PYRIDINE.

**Rubidine**  $C_2H_5N$ . (230°). S.G. 1.017. Occurs in coal-tar (Thenius, *Rep. Chim. app.* 4, 181). Liquid, sl. sol. water, miscible with alcohol and ether. Its salts redden in the air. Bleaching-powder gives a red colour. Colours acidified fir-wood red. —  $B'_2H_5PtCl_6$ : reddish crystalline powder.

**RUBIDIUM**. Rb. At. w. 85.2. Mol. w. unknown. Melts at c. 38.5° (Bunsen, *A.* 125, 367). S.G. c. 1.52 (B., *l.c.*). Refraction-equivalent 12.1 (Gladstone, *Pr.* 18, 49); 11.6 (Kannonikoff, *J. R.* 1884 [1] 119). Chief lines in emission-spectrum are two in the red,  $Rb_\alpha$  and  $Rb_\beta$ , 7800 and 6297; and two in the violet,  $Rb_\gamma$  and  $Rb_\delta$ , 4216 and 4206 (Kirchoff & Bunsen, *P.* 113, 337; Lecoq de Boisbaudran, *Spectres lumineux* [1874] 46; v. also B. A. 1884, 438). Beketoff (*J. R.* 1888, 363) gives  $[Rb^2O] = 94,900$ .

**Occurrence**.—Never free. Salts are widely distributed, but in very small quantities, along with salts of Cs, and frequently also salts of Li, K, and Na. Many *lepidolites* contain Rb salts amounting to c. .24 p.c. Rb (K. a. B., *P.* 113, 337; 119, 1; Grandeau, *A. Ch.* [3] 67, 155; Allen, *Am. S.* [2] 34, 367). Traces of Rb salts have been found in specimens of *orthoclase* (Erdmann, *J. pr.* 80, 377, 448; Laspeyres, *A.* 134, 349; *petalite* (Grandeau, *l.c.*); *nicas* (Schrötter, *J. pr.* 85, 458); *basalt* (Engelbach, *A.* 135, 126); *carrollite* (Erdmann, *l.c.*); in *alum* obtained on the island of Volcano (Cossa, *Acc. dei Lincei*, 11, 9); *saltpetre* (Dieulafoy, *C. R.* 98, 1545). Small quantities of Rb salts, varying from c. .0002 to c. .03 g. RbCl per litre, occur in mineral springs (v. Bunsen, *A.* 122, 347; Grandeau, *A. Ch.* [3] 67, 155; Schrötter, *J. pr.* 85, 458; Redtenbacher, *J. pr.* 85, 458; Böttger, *J. pr.* 89, 378). Traces of Rb salts have been found in *sea water* (Sonstadt, *C. N.* 22, 25, 44); in *funaroles* giving out boric acid (Hofmann, *J. C. T.* 1863, 354); in *coffee, tea, cocoa*, and *tobacco* (Grandeau, *l.c.*); in the *ashes of beetroot* (G., *l.c.*; Lefèvre, *C. R.* 55, 430); in the *ashes of various plants* (von Than, *A. Suppl.* 2, 84); in *normal human urine* (Schiaparelli & Peroni, *G.* 10, 390). According to Lockyer a well-marked Rb line occurs in the solar spectrum (*Pr.* 27, 279).

**Historical**.—In 1860 Bunsen applied the method of spectroscopic analysis, then being worked out by him along with Kirchoff, to the examination of the residue obtained by evaporating very large quantities of the water from a mineral spring at Dürkheim. Two red lines appeared which were not known to belong to any element. By further investigation Bunsen separated the chloride of the element, and on electrolysis the molten chloride he obtained metallic globules, which rose to the surface and took fire. By strongly heating an intimate mixture of the carbonate of the new element with finely divided charcoal and distilling into a receiver under rock-oil, Bunsen obtained the metal in some quantity. The name rubidium was given because of the characteristic lines in the red part of the spectrum (*ruber* = dark red) (v. Bunsen, *A.* 113, 337; 122, 347).

**Formation**.—1. By distilling the mixture of  $Rb_2CO_3$  and C obtained by carbonising  $Rb_2H$  tartrate (Bunsen, *l.c.*; Setterberg, *A.* 211, 100).—2. By distilling a mixture of  $RbOH$  and Al (Beke-

toff, *J. R.* 1888, 363).—3. By passing a strong electric current through molten  $RbCl$ , the positive electrode being graphite, and the negative an iron wire, globules of Rb rise to the surface, and there take fire. If the negative electrode is surrounded with H (v. LITHIUM, vol. iii. p. 148), a small blue substance is formed, which dissolves in water with formation of  $RbOH$  and H; this blue solid is probably a lower chloride than  $RbCl$ , perhaps  $Rb_2Cl$  (Bunsen, *l.c.*).

**Preparation**.—The saline residues from the manufacture of lithium compounds from Saxon *lepidolite* (at Struve's works in Leipzig) were found by Bunsen (*l.c.*), Heintz (*J. pr.* 87, 310), and Erdmann (*J. pr.* 86, 294) to be rich in Rb salts. The specimen examined by Bunsen contained 19.75 p.c.  $RbCl$ . Cossa (*B.* 11, 811) recommended the natural alum from the island of Volcano as a good raw material for preparing Rb salts.

1. Bunsen's method (*A.* 122, 351) for separating Rb is based on the different solubilities in water of the platinoclides of K, Rb, and Cs; these solubilities at 17° are in the ratio of 15:2:1. One kilo. of the saline residue from the preparation of Li compounds from Saxon *lepidolite* is dissolved in 2.5 kilos. water, and *ppd.*, when cold, by 30 g. Pt in *agua regia*. After settling the liquid is drawn off, and the *pp.* is boiled 25 times in succession with small quantities of water (1.5 kilos. in all), each portion being poured into the liquid which was drawn off from the *pp.* by the  $PtCl_4$ . The 4 kilos. of liquid and washings are evaporated to 2.5 kilos. While this evaporation is proceeding, the washed platinoclride *pp.* is dried at 100°, heated nearly to redness in a stream of H until a mixture of Pt with  $RbCl$ , and perhaps a little  $CsCl$ , remains (if the solid melts reduction is incomplete); and the  $RbCl$  is dissolved out in hot water. The Pt which remains is dissolved in *agua regia*, and added to the liquid which has been evaporated. The *pp.* is washed with small quantities of water as before, dried, and reduced in H, the supernatant liquid and washings being evaporated. The reduced Pt is dissolved and added to the liquid, and so on. These processes are repeated seven or eight times. From 1 kilo. material Bunsen obtained .125 kilo.  $RbCl$ , containing 3.4 p.c.  $KCl$  and a little  $CsCl$ . To separate  $KCl$ , the approximately pure  $RbCl$  is dissolved in water (36 g. in 1 litre), heated to boiling, and a boiling solution of  $PtCl_4$  (30 g. Pt in *agua regia*, diluted to 1 litre) is added; the *pp.* is washed repeatedly with water at 40°–50°, then dried, and reduced in H; the  $RbCl$  is dissolved in water, and the Pt in *agua regia*, and these processes are repeated until the  $RbCl$  shows no trace of the red lines of K in the spectro-scope. Finally, Bunsen separated  $CsCl$  by transforming the chlorides into carbonates, and treating the powdered salts with boiling absolute alcohol until the insoluble  $RbCl$  ceased to show the blue lines of Cs in the spectroscopes ( $RbCl$  is insoluble, while  $CsCl$  dissolves, in absolute alcohol). This process has been modified by Heintz (*J. pr.* 87, 310), Grandeau (*A. Ch.* [3] 67, 155), Piccard (*J. pr.* 86, 449), Böttger (*J. pr.* 89, 378), Schrötter (*J. pr.* 85, 458), de Boisbaudran (*B.* [2] 17, 551), and others.

2. Redtenbacher's method (*J. pr.* 95, 148) is

based on the different solubilities of the alums of K, Rb, and Cs; the solubilities in water, at 17°, are as 22:4:1. The method has been modified by Stolba (*J. pr.* 99, 49), Godeffroy (*A.* 181, 176), Petersen (*D. P. J.* 224, 176), Cossa (*B.* 11, 811), Setterberg (*A.* 211, 100), Robinson & Hutchins (*C. N.* 49, 253). The mother-liquor from which  $\text{Li}_2\text{CO}_3$  has been separated by Schrötter's method (vol. iii. p. 149) is evaporated with  $\text{H}_2\text{SO}_4\text{aq}$ , with addition of  $\text{Al}_2(\text{SO}_4)_3$ , whereby Rb and Cs alums are obtained mixed with K alum. Or lepidolite may be decomposed by heating with  $\text{H}_2\text{SO}_4$  and  $\text{CaF}_2$ , the residue boiled with five or six volumes water, KOH added equal to 5 p.c. of the quantity of lepidolite used, the whole boiled with water, and filtered hot, when the alums crystallise out on cooling (Stolba, *loc.*). The alums are dissolved in half their weight of boiling water, half as much cold water is added, and after stirring the whole is let cool to 45°, when almost all the Rb and Cs alums separate, leaving much K alum in solution. The solution in water, and cooling, are repeated, temperature being allowed to fall to 40°; the alum which separates is dissolved in water equal to half the weight of the original quantity of mixed alums, boiled for some time, and allowed to cool to 60° while being stirred. The crystals which separate are almost pure Cs alum; the mother-liquor, when evaporated, yields almost pure Rb alum.

To prepare the metal, RbCl or Rb alum can be transformed into RbOH, and Rb prepared therefrom; or the RbOH may be dissolved in the proper quantity of tartaric acid to form RbH tartrate, which may then be charred, and Rb obtained from the mixture of  $\text{Rb}_2\text{CO}_3$  and C so formed.

To prepare RbOH, the RbCl is converted into  $\text{Rb}_2\text{SO}_4$  by  $\text{H}_2\text{SO}_4\text{aq}$ , the  $\text{Rb}_2\text{SO}_4$  is dissolved in water, boiled, BaOaq is added, the liquid being kept boiling. BaSO<sub>4</sub> is removed by decantation, and the liquid is evaporated to dryness in a silver dish as quickly as possible. RbOH is obtained from Rb alum by dissolving in hot water, ppg.  $\text{Al}_2\text{O}_3$  by slight excess of  $\text{NH}_4\text{aq}$ , filtering hot, evaporating to dryness in a Pt dish, strongly heating till  $(\text{NH}_4)_2\text{SO}_4$  is removed, and then proceeding to decompose the  $\text{Rb}_2\text{SO}_4$  by BaOaq as already described. RbOH is mixed with Al clippings in the ratio 2RbOH:Al (=1 part Al to 7.5 parts RbOH), and the mixture is heated to full redness in a furnace, in an iron cylinder, connected by an iron tube with a glass receiver. The Rb distils over, and appears like Hg in the receiver. As H is given off, the Rb is surrounded by a non-oxidising atmosphere ( $4\text{RbOH} + 2\text{Al} = \text{Rb}_2\text{O} \cdot \text{Al}_2\text{O}_3 + 2\text{Rb} + 2\text{H}_2$ ). From 28 to 33 p.c. of the Rb in RbOH is obtained (Beketoff, *J. R.* 1888, 363; abstracts in *C. J.* 58, 108, and *B.* 21, Ref. 424). For a description of the method of preparing Rb from  $\text{Rb}_2\text{CO}_3$  and C v. Bunson (*A.* 125, 367) and Setterberg (*A.* 211, 100). An explosive compound similar to the compound of K and CO (this vol. p. 300) is liable to be formed.

For a method of separating Rb from Cs and K, based on the formation of double compounds of RbCl with  $\text{SbCl}_3$ , and with  $\text{SnCl}_4$ , v. Muthmann (*B.* 26, 1019 [1893]).

**Properties.**—A very lustrous, white metal,

with an extremely faint tinge of yellow. Soft as wax, even at  $-10^\circ$ ; melts very easily (*c.*  $38.5^\circ$ ). Lighter than water. Bunson (*A.* 125, 367) made one determination of S.G., which gave 1.62, but the result is not final. Heated in absence of O, the metal distils below redness, forming a blue vapour. Rb dissolves in liquid  $\text{NH}_3$  (Seeley, *C. N.* 23, 169). When exposed to air Rb is at once covered with a greyish-blue film, which is supposed to be a suboxide; much heat is produced, and the metal soon takes fire. Decomposes cold water very rapidly, with evolution of H, which takes fire. Rb is the most positive element next to Cs. It closely resembles K in its chemical relations (*v. ALKALIS, METALS OF THE*, vol. i. p. 114). The at. w. of Rb has been determined (1) by determining Cl in RbCl by Bunson (*P.* 113, 339; 115, 584 [1861]), Piccard (*J. pr.* 86, 454 [1862]), and Godeffroy (*A.* 181, 189 [1875]); (2) by determining V.D. of RbCl and RbI at  $c. 1200^\circ$  (Scott, *Pr. E.* 14, 410). The S.H. of Rb has not been determined; but from observations of the molecular heats of RbCl and  $\text{Rb}_2\text{CO}_3$ , and comparisons of these with those of the corresponding salts of metals that have normal atomic heats, it is probable that the atomic heat of Rb is *c.* 6.4, and, therefore, that the S.H. is *c.* .075. The atom of Rb is monovalent in the gaseous molecules RbCl and RbI.

**Reactions and Combinations.**—1. Rapidly oxidises in air; much heat is produced, and the metal ignites. Beketoff (*J. R.* 1888, 363) gives  $[\text{Rb}^2\text{O}] = 94,900$ .—2. Decomposes cold water, with rapid evolution of H and production of RbOHAq; Beketoff (*loc.*) gives  $[\text{Rb}^2\text{H}^2\text{Oaq}] = 96,400$ , with formation of RbOHAq and H.—3. Burns in vapour of chlorine, bromine, iodine, sulphur, and arsenic, forming compounds with those elements (Bunson, *loc.*).

**Detection and Estimation.**—Phosphomolybdic acid gives a yellow pp. insol. acids (Debray, *Bl.* [2] 5, 404). Silicotungstic acid ( $\text{SiW}_{12}\text{O}_{42} \cdot \text{H}_{12} \cdot x\text{H}_2\text{O}$ ) ppt. Rb salts, but not salts of K (Godeffroy, *B.* 9, 1365). As Cs salts are pptd. by  $\text{SbCl}_3$  in conc. HClAq, added to solutions containing conc. HCl (as  $6\text{CsCl} \cdot \text{SbCl}_3$ ), while Rb salts give no pp., Rb can be separated from Cs salts by addition of HClAq and  $\text{SbCl}_3$  in HClAq (*G. B.* 8, 9). Rb is best detected by the spectroscope. The most characteristic lines are in the blue-violet,  $\text{Rb}_\lambda (\lambda = 4206)$ , and  $\text{Rb}_\beta (\lambda = 4216)$ : .0002 mgm RbCl can be detected (Bunson, *loc.*). Rb is determined in the form of RbCl. For the separation of Rb from K, and estimation of the Rb, v. Bunson (*loc.*). Bunson determined RbCl in presence of CsCl by finding the sum of the two chlorides, then estimating the total Cl, and calculating the quantity of each salt.

**Rubidium, amalgam of.** When conc. RbClAq is electrolysed, using Hg as negative electrode, a solid, white, lustrous, crystalline amalgam is formed. Decomposes cold water rapidly; becomes oxidised superficially in air, and then deliquesces with formation of RbOH. Is electropositive to K amalgam (Bunson, *A.* 122, 347).

**Rubidium, bromide of.** RbBr. Formula probably molecular, from analogy of RbCl and RbI. Formed by burning Rb in Br. Also by saturating HBrAq with  $\text{Rb}_2\text{CO}_3$ , and evaporating.

White, lustrous, regular octahedra. S. 98 at 5°, 104·8 at 16° (Reissig, A. 127, 33). Melts at c. 683° (Carnelley, C. J. 33, 279). Combines with IBr, to form RbBr.IBr; and with Br to form RbBr.Br<sub>2</sub> (Wells a. Wheeler, Am. S. [3] 43, 475).

Rubidium, chloride of. RbCl. Mol. w. 120·57. V.D. at 1200°–1500° 69·7 (Scott, Pr. E. 14, 410). Melts at c. 710° (Carnelley, C. J. 33, 279). By burning Rb in Cl. Also by saturating HClAq with Rb<sub>2</sub>CO<sub>3</sub>, evaporating, and crystallising from water. Also by reducing Rb<sub>2</sub>PtCl<sub>6</sub> in H<sub>2</sub> and dissolving out RbCl in water (cf. Preparation, p. 411). White, lustrous, cubical crystals; unchanged in air; decrepitates when heated, and then melts, and volatilises at a very high temperature. S. 76·38 at 1°, 82·89 at 7°; sol. alcohol (Bunsen, Lc.). Molten RbCl is a good conductor of electricity (Hampe, Chem. Zeitung, 1887, No. 54). Double compounds: RbCl combines with many metallic chlorides; some at any rate of the products, e.g. the platinum- and platinum-chlorides Rb<sub>2</sub>PtCl<sub>6</sub> and Rb<sub>2</sub>PtCl<sub>4</sub>, are best regarded as Rb salts of acids containing metals and Cl. The following compounds have been prepared: M=RbCl. — 6M.SbCl<sub>3</sub> (1); 3M.2SbCl<sub>3</sub> (6); 6M.BiCl<sub>3</sub> (1); 2M.CdCl<sub>2</sub>, M.CdCl<sub>2</sub>.xH<sub>2</sub>O (1); 2M.CrCl<sub>3</sub>.aq (2); 2M.CuCl<sub>2</sub> (1); M.AnCl<sub>3</sub> (3); 3M.FeCl<sub>3</sub> (1); 2M.FeCl<sub>3</sub>.aq (2); 2M.MnCl<sub>2</sub>.3aq (1); 2M.HgCl<sub>2</sub>, 2M.HgCl<sub>2</sub>.2aq, 2M.HgCl<sub>2</sub>, M.4HgCl<sub>2</sub> (1); 2M.NiCl<sub>2</sub> (1); 2M.PtCl<sub>4</sub> (4); 2M.PtCl<sub>2</sub> (5); 3M.TiCl<sub>3</sub> (2); 2M.SnCl<sub>4</sub> (1); 2M.ZnCl<sub>2</sub> (1).

References to above.—(1) Godefroy, B. 8, 9; (2) Neumann, A. 244, 329; (3) Rosenbladt, B. 19, 2535; (4) Nilson, Bl. [2] 27, 210; (5) Bunsen, A. 122, 347; (6) Muthmann, B. 26, 1019, 1425.

RbCl also combines with IBr to form RbCl.IBr; with ICl, to form RbCl.ICl; with BrCl, to form RbCl.BrCl; and with Br to form RbCl.Br<sub>2</sub> (Wells a. Wheeler, Am. S. [3] 43, 475).

Rubidium, cyanide of. Setterberg (A. 211, 100) probably obtained a cyanide of Rb by passing dry HCN into an alcoholic solution of RbOH. Reissig (A. 127, 33) failed to obtain the salt free from products of decomposition.

Rubidium, ferrocyanide of; v. vol. ii. p. 335.

Rubidium, fluoride of. RbF. Formula probably molecular, from analogy of RbCl and RbI. S.G. 3·202 at 16·5° (Clarke, Am. S. [3] 13, 293). Melts at c. 753° (Carnelley, C. J. 33, 279). Forms a double compound with uranyl fluoride, 4RbF.UO<sub>2</sub>F<sub>2</sub>.6aq (Ditte, C. R. 91, 186).

Rubidium, hydroxide of. RbOH. A white, brittle solid, with slight greyish tinge; very alkaline and caustic; easily sol. water, with production of much heat; sol. alcohol. Formed by decomposing H<sub>2</sub>O by Rb; also by boiling Rb<sub>2</sub>SO<sub>4</sub> till air is driven out, adding BaO<sub>2</sub> gradually, keeping the liquid boiling till BaSO<sub>4</sub> ceases to be formed, decanting from BaSO<sub>4</sub>, which separates out rapidly, and evaporating in a silver dish. Melts below redness; is not decomposed by heating. When molten attacks Pt. Beketoff (J. R. 1888, 363) gives [Rb, O, H] = 164,800; [Rb·O, H·O] = 69,900.

Rubidium, iodide of. RbI. Mol. w. 211·63. V.D. 110·8 at 1200°–1500° (Scott, Pr. E. 14, 410). Melts at c. 642° (Carnelley, C. J. 33, 279). Lustrous, white, regular octahedra; unchanged

in air. S. 137·5 at 6·9°, 152 at 17·4°. Formed by saturating HIAq with Rb<sub>2</sub>CO<sub>3</sub>, evaporating, and crystallising from water. Also by heating Rb in I vapour (Reissig, A. 127, 33). RbI combines with I to form RbI.I<sub>2</sub> (Wells a. Wheeler, Am. S. [3] 43, 475).

Rubidium, oxides of. No oxide of Rb has been isolated. Rb burns in air, possibly with formation of an oxide and peroxide similar to K<sub>2</sub>O and K<sub>2</sub>O<sub>2</sub>. The greyish-blue film which is formed on the surface of the metal when exposed to the air is perhaps a suboxide. According to Beketoff (J. R. 1888, 363), the thermal value of [Rb<sub>2</sub>O] is 94,900.

Rubidium, salts of. The principal salts formed by replacing H of oxyacids by Rb are borate, carbonates, chlorate and perchlorate, chromate and dichromate, molybdate, nitrate, oxalate, silicotungstate, sulphate, and thio-sulphate (v. CARBOGATES, NITRATES, &c.).

Rubidium, silicofluoride of. Rb<sub>2</sub>SiF<sub>6</sub>. White, regular crystals. S.G. 3·338 at 20°. S. c. 16 at 20°, 1·35 at 100°. By ppg. hot Rb alum solution by CuSiF<sub>6</sub> (Stolba, J. pr. 102, 1).

M. M. P. M.

RUBIJERVINE v. JERVINE.

RUE OIL. The essential oil (c. 229°) obtained by distilling *Ruta graveolens* contains methyl ennyl ketone C<sub>11</sub>H<sub>20</sub>O (224°), a ketone C<sub>12</sub>H<sub>22</sub>O (232°), and a small quantity of terpene (Gerhardt, C. R. 26, 225, 361; Calours, O. R. 26, 262; Greville Williams, T. 1858 [1] 99; A. 107, 374; Hallwachs, A. 113, 103; Harbordt, A. 123, 293). By boiling oil of rue with nitric acid (S.G. 1·2) an acid C<sub>11</sub>H<sub>17</sub>N<sub>3</sub>O<sub>4</sub> may be obtained (Chiozza, A. 85, 225; Alexejeff, Z. 1865, 736). This acid is a heavy oil, forming KA' and NaA', crystallising from alcohol in greenish-yellow tables (Limpach, A. 190, 298).

RUFICOCIN v. CARMINIC ACID.

RUFIGALLIC ACID v. HEXA-OXY-ANTHRAQUINONE.

RUFIN C<sub>20</sub>H<sub>12</sub>O<sub>8</sub>. A product of the action of heat on phlorizin (Mulder, Rev. Scientif. 3, 50; Stas, A. 50, 198). Dark-red resin, sol. alcohol, nearly insol. ether and water. Its alkaline solutions are red. Ac<sub>2</sub>O forms C<sub>20</sub>H<sub>10</sub>AcO<sub>8</sub> (Schiff, A. 156, 5).

RUFIOPINE is TETRA-OXY-ANTHRAQUINONE.

RUFOL v. DI-OXY-ANTHRACENE.

RUTHENAMMINES v. RUTHENIUM-AMMONIUM COMPOUNDS, p. 418.

RUTHENATES v. RUTHENIUM, SALTS OF OXYACIDS OF, p. 417.

RUTHENITES v. RUTHENIUM, SALTS OF OXYACIDS OF, p. 417.

RUTHENIUM. At. w. 101·4. Mol. w. unknown. Melts at highest temperature attainable by O-H flame, which is above 2000° (Deville a. Debray, A. Ch. [3] 56, 385). S.G. 12·26 at 0° (crystallised) (D. a. D., C. R. 83, 928); older determinations varied from 8·6 to 11·4. Joly (C. R. 116, 430) gives S.G. of Ru melted in an electric furnace as 12·63 at 0° referred to water at 4°. S.H. 0·611 from 0° to 100° (Bunsen, P. 141, 1). C.E. at 40° (linear) 0·00009363 (Fizeau, C. R. 68, 1125).

Occurrence.—In many platinum ores; Ru is a constant ingredient of osmiridium (vol. iii. p. 47), the quantity varying from 3 to 6 p.c. (v. Claus, A. 56, 267; 59, 234; Gibbs, Am. S. [2] 24,

427; 81, 68; 84, 841). Wöhler found  $\text{Ru}_2\text{S}_3$  in *laurite*, a rare mineral occurring in Borneo and in Oregon (*J. pr.* 98, 226).

In 1828 Osann (*P.* 13, 283; 14, 329; *cf.* 64, 197) thought he had discovered three new metals in the portion of a Pt ore insol. in *aqua regia*; to these metals he gave the names *polin*, *pluranium*, and *ruthenium* (from *Ruthenia* = Russia). In 1845 Claus (*A.* 56, 257; 59, 234; *cf.* 63, 359) examined the substance called ruthenium oxide by Osann, and found it to consist chiefly of  $\text{SiO}_2$ ,  $\text{TiO}_2$ ,  $\text{Fe}_2\text{O}_3$ , and  $\text{ZrO}_2$ ; from this material Claus isolated a new metal, to which he assigned Osann's name, *ruthenium*.

**Formation.**—1. By reducing  $\text{Ru}_2\text{O}_3$  by heating in H or C.—2. By strongly heating  $(\text{NH}_4)_2\text{RuCl}_6$ ,  $(\text{NH}_4)_2\text{RuCl}_4$ ,  $\text{Ru}(\text{NH}_4)_2\text{Cl}_2$ , or  $\text{Ru}(\text{NH}_4)_2\text{Cl}_2 \cdot \text{H}_2\text{O}$ .—3. By heating  $\text{RuSn}_2$  in a graphite boat in a stream of HCl.

**Preparation.**—Deville a. Debray (*C. R.* 82, 926) prepared pure Ru by heating the ordinary metal in a stream of O till every trace of Os was removed as  $\text{OsO}_4$  (vol. iii. p. 646), fusing with KOH and  $\text{KNO}_3$ , dissolving in water, saturating with Cl, and distilling off  $\text{RuO}_4$  into  $\text{HClAq}$ , by heating in a stream of Cl on a water-bath, ppg.  $\text{Ru}_2\text{O}_3$  by adding alcohol to the solution of  $\text{KRuO}_4$ , heating the pp. in coal-gas till reduced to Ru, melting in a graphite crucible with 5 to 6 parts pure tin, treating with boiling  $\text{HClAq}$ , washing and drying the crystalline  $\text{RuSn}_2$ , which remained, and heating this strongly in a graphite boat in a stream of HCl.—2. Osm-iridium is mixed with 2 parts  $\text{KNO}_3$  and 1 part KOH, and the mixture is heated to redness in a large silver crucible, embedded in MgO in an earthenware crucible; the molten portion is poured off, and the residue is heated with more  $\text{KNO}_3$  and KOH. The fused mass is lixiviated with water; the orange solution, which contains KOH and K salts of  $\text{HNO}_3$ ,  $\text{HNO}_2$ ,  $\text{H}_2\text{OsO}_6$ , and  $\text{H}_2\text{RuO}_4$ , is neutralised by  $\text{HNO}_3\text{Aq}$ , when a black pp. forms containing  $\text{OsO}_4 \cdot x\text{H}_2\text{O}$  and  $\text{Ru}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ . This pp. is filtered off, the filtrate being set aside, and is washed and boiled with  $\text{HClAq}$  and  $\text{HNO}_3\text{Aq}$  in a retort connected with a receiver which is kept very cold; the boiling is continued till a drop of the distillate, when brought alternately into the oxidising and reducing parts of the Bunsen flame, ceases to give a bright flash in the former, i.e. until  $\text{OsO}_4$  ceases to distil off. The residue, which contains  $\text{RuCl}_3$  and  $\text{RuCl}_4$ , is dissolved in a little water, excess of  $\text{NH}_4\text{Cl}$  is added to the hot conc. solution, the liquid is poured off from  $(\text{NH}_4)_2\text{RuCl}_6$ , evaporated and mixed with more  $\text{NH}_4\text{Cl}$ , when  $(\text{NH}_4)_2\text{RuCl}_6$  ppts. Excess of  $\text{NH}_4\text{Cl}$  is removed from the pps. by washing with alcohol. By strongly heating the pps. Ru is obtained. The solution filtered from the pp. of  $\text{OsO}_4 \cdot x\text{H}_2\text{O}$  and  $\text{Ru}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  contains  $\text{OsO}_4$  and  $\text{RuO}_4$ ; it is made strongly acid by  $\text{HClAq}$ ,  $\text{OsO}_4$  is distilled off, the solution is evaporated till most of the  $\text{KNO}_3$  crystallises out, the mother-liquor is evaporated to dryness, the residue is dissolved in water, and  $\text{Ru}_2\text{S}_3$  is ppd. by adding  $(\text{NH}_4)_2\text{SAq}$  and then acidifying; after washing and drying, the  $\text{Ru}_2\text{S}_3$  is roasted, and the  $\text{Ru}_2\text{O}_3$  so formed is reduced by heating in H, or by strongly heating in a graphite crucible; or the  $\text{Ru}_2\text{O}_3$  may be dissolved in  $\text{HClAq}$ , and  $\text{NH}_4\text{-Ru}$  chlorides obtained from this solution and decomposed by

heat (Claus, *J. pr.* 85, 129; Carey Lea, *Am. S.* [2] 88, 88).

For other methods of separating Ru from osm-iridium v. Deville a. Debray (*A. Ch.* [3] 56, 885; *C. R.* 83, 927; Fremy, *A. Ch.* [3] 44, 385; Gibbs, *Am. S.* [2] 34, 343; 37, 61). Debray obtained *ruthenium* in crystals by dissolving the spongy metal in molten lead, heating strongly, and, after cooling, dissolving out the lead (with which Ru does not alloy) in  $\text{HNO}_3\text{Aq}$  (*C. R.* 90, 1195).

**Properties.**—A white, lustrous, hard, heavy, brittle metal. As obtained by heating the double ammonium chlorides, Ru forms a white spongy mass; the metal formed by reducing the oxide by H appears in white porous fragments, which can be powdered; after fusion in an electric furnace Ru appears greyish (Joly, *C. R.* 116, 430). Next to Os, Ru is the most infusible metal; small pieces can be melted at the highest temperature of the O-H flame (D. a. D., *A. Ch.* [3] 56, 385); a little  $\text{RuO}_4$  is formed and then decomposed to  $\text{RuO}_2$  (D. a. D., *C. R.* 80, 457). Insoluble in all acids if in compact pieces; very finely divided Ru dissolves slightly and slowly in boiling *aqua regia*. Not attacked by molten  $\text{KHSO}_4$ ; oxidised to  $\text{K}_2\text{RuO}_4$  by fusion with KOH,  $\text{KNO}_3$ , or  $\text{KClO}_3$ . Ru dissolves in molten Zn or Pb; treatment with  $\text{HNO}_3\text{Aq}$  leaves the Ru undissolved. Small quantities of Ru when alloyed with Pt metals soluble in acids go into solution, with the Pt metals, in these acids. Finely divided Ru combines with O, when heated in O or in air.

Ru is closely related to Rh and Pd, and less closely, but very distinctly, to Os, Ir, and Pt; v. NOBLE METALS, vol. iii. p. 628.

The atomic weight of Ru has been determined (1) by determining the ratio of Ru to KCl in  $\text{K}_2\text{RuCl}_6$  (Claus, *P.* 65, 218 [1845]; (2) by analyses of the salts  $\text{M}_2\text{Ru}(\text{NO})\text{Cl}_4$ , where  $\text{M} = \text{K}, \text{Na}, \text{and } \text{NH}_4$  (Joly, *C. R.* 107, 994; 108, 946 [1899]; (3) by determining V.D. of  $\text{RuO}_4$  (Debray a. Joly, *C. R.* 106, 328); (4) by measuring S.H. of Ru (Bunsen, *P.* 141, 1). Claus's determinations gave values from 102.2 to 104.8 for the at. wt.

The only compound of Ru whose mol. weight is known in the gaseous state is  $\text{RuO}_4$ ; the valency of the atom of Ru cannot be determined from this datum.

**Reactions and Combinations.**—1. Finely divided Ru, when heated to redness in air or in oxygen, rapidly absorbs 18.5 p.c. O (Claus, *J. pr.* 42, 364); after 10 hours, c. 23 p.c. O has combined (D. a. D., *C. R.* 87, 441); the product is a mixture of  $\text{RuO}_2$  and Ru (Claus failed to obtain a lower oxide than  $\text{RuO}_4$  in this way). Crystals of  $\text{RuO}_4$  are obtained by heating the metal in a tube in a rapid stream of O; according to Dobray and Joly (*C. R.* 106, 1494),  $\text{RuO}_4$  is formed and then decomposed (v. RUTHENIUM TETROXIDE, p. 417).—2. Heated in chlorine, a small portion is changed to a chloride; mixed with sodium chloride and heated in chlorine,  $\text{Na}_2\text{RuCl}_6$  is formed (Claus, *l.c.*).—3. Spongy Ru is said to form  $\text{HClAq}$  when placed in chlorine water; and to produce chlorides in solutions of hypochlorites, O being given off (Schönbein, *J. pr.* 98, 76).—4. Very finely divided Ru dissolves slightly when kept in boiling *aqua regia* for some time,  $\text{RuCl}_3$  being formed.—5.  $\text{M}_2\text{RuO}_6$

soluble in water. is formed by fusing Ru with caustic alkalis, alkali chlorates, or alkali nitrates. Alkaline earth nitrates or chlorates also form ruthenates (v. RUTHENATES, p. 417).

**Detection.**—A few mgs. of the substance to be tested are heated, in a spoon of Pt, with excess of  $\text{KNO}_3$  until the whole melts and ceases to give off gas; when cold, the mass is dissolved in water, when a strongly coloured orange-yellow solution is obtained; a little  $\text{HNO}_3$  aq is added to this solution, followed by  $\text{HCl}$  aq, and warming till the voluminous black pp., produced by  $\text{HNO}_3$  aq, dissolves to an orange-yellow solution;  $\text{H}_2\text{S}$  is passed into this liquid, until it appears black from the presence of suspended Ru sulphide (or oxysulphide); on filtering, an azure-blue liquid is obtained, probably containing  $\text{RuCl}_3$  (Bunsen, A. 146, 265). For estimation v. Deville a. Debray (C. R. 83, 927).

**Ruthenium, alloys of.** An alloy with iridium was obtained by Deville a. Debray (A. Ch. [3], 56, 385). A crystalline alloy with tin,  $\text{RuSn}_3$ , is formed by melting Ru with 10 to 15 parts Sn, and when cold treating with  $\text{HCl}$  aq. The tin is removed, and crystalline Ru remains, by heating, in a graphite boat, in  $\text{HCl}$  gas (D. a. D., l.c.; v. also C. R. 83, 927). Ru alloys with zinc; much heat is produced (D. a. D., l.c.). Ru dissolves in molten lead, but separates out again on cooling (Debray, C. R. 90, 1195).

**Ruthenium, ammonio-salts of; v. RUTHENIUM-AMMONIUM COMPOUNDS, p. 418.**

**Ruthenium, chlorides of.** Two chlorides,  $\text{RuCl}_3$  and  $\text{RuCl}_4$ , are obtained by heating finely divided Ru in a stream of Cl. No other chloride has been isolated; the existence of double compounds of  $\text{RuCl}_3$  with alkali chlorides is doubtful. The molecular weights of the chlorides are not known.

**RUTHENIUM DICHLORIDE  $\text{RuCl}_3$ .** (*Ruthenous chloride. Ruthenoso-chloride.*) Prepared by heating very finely divided Ru in a stream of Cl. Action begins at c.  $360^\circ$  (Joly, C. R. 114, 291) with formation of  $\text{RuCl}_3$ , which is removed by subliming, and the temperature is kept at dull redness for an hour or two; the residue is powdered, and again heated in Cl; and this treatment is repeated several times (Claus, A. 59, 234). A black crystalline mass; insoluble in water, acids, or alkali solutions. The azure-blue liquid formed by the action of reducers, such as Zn or  $\text{H}_2\text{S}$ , on solutions of  $\text{RuCl}_3$ , was thought by Claus (l.c.) to contain  $\text{RuCl}_3$ .

**RUTHENIUM TRICHLORIDE  $\text{RuCl}_4$ .** (*Ruthenous, or ruthenoso-ruthenic, chloride. Sesquichloride of ruthenium.*) Obtained, as a brown, crystalline, very hygroscopic solid, by dissolving  $\text{Ru(OH)}_3$  (Claus, A. 59, 234), or  $\text{RuO}_3$  (Joly, C. R. 107, 994), in  $\text{HCl}$  aq, and evaporating to dryness. Joly (C. R. 114, 291) obtained  $\text{RuCl}_4$  by heating finely divided Ru at  $360^\circ$  to  $440^\circ$  in a mixture of CO and Cl, the Cl being in excess. Claus says that  $\text{RuCl}_4$  is sol. water, with partial decomposition to an insol. oxychloride; and that, on heating, the solution decomposes with separation of a black powder (partly oxychloride, partly  $\text{RuO}_3\text{H}_2$ ), the colouring power of which is so great that 1 mgm. suffices to make 500 c.c. water appear quite black. Joly (C. R. 114, 291) says that  $\text{RuCl}_4$ , prepared by heating Ru in Cl and CO, is insol. cold water, acid solutions,  $\text{CCl}_4$ ,  $\text{CS}_2$ ,

$\text{CHCl}_3$ ,  $\text{Et}_2\text{O}$ , or  $\text{PCl}_5$ ; it is decomposed slowly by hot water; slowly dissolved by digesting with 50 times its weight of absolute alcohol, in a sealed tube. Solution in alcohol is purple-violet; slowly decomposes in moist air, more rapidly at  $60^\circ$ , giving  $\text{RuCl}_3\text{OH}$  (v. RUTHENIUM HYDROXYCHLORIDE, p. 416).  $\text{RuCl}_4$  absorbs  $\text{NH}_3$  to form  $2\text{RuCl}_4\cdot 7\text{NH}_3$ ; another compound containing  $\text{NH}_3$ , viz.  $\text{Ru}_2\text{Cl}_9(\text{OH})_2\cdot 7\text{NH}_3\cdot 3\text{H}_2\text{O}$ , is formed by throwing  $\text{RuCl}_4$  in small successive quantities into cold saturated  $\text{NH}_3$  aq and then heating to  $40^\circ$  (Joly, C. R. 115, 1299).

**Double salts. Chlor-ruthenites,**  $\text{RuCl}_4\cdot 2\text{MCl}$ , or  $\text{M}_2\text{RuCl}_6$ ;  $\text{M}=\text{NH}_4$ , K, Na (Claus, A. 59, 234; 63, 359). Formed by evaporating  $\text{RuO}_3\text{H}_2$  in  $\text{HCl}$  aq nearly to dryness, dissolving in water, and adding conc. solution of the alkali chloride; also by heating a mixture of Ru with KCl or NaCl in Cl (Joly, C. R. 107, 994). The potassium salt, which seems to be the most definite, is a brownish-violet, crystalline powder, scarcely sol. cold water, somewhat sol. boiling water, insol. alcohol of 80 p.c.

Joly (C. R. 108, 854) obtained *ruthenium nitrosochloride*  $\text{RuCl}_3\cdot \text{NO}\cdot \text{H}_2\text{O}$ , by heating  $\text{RuCl}_3$  with a large excess of  $\text{HNO}_3$  aq, and evaporating at  $120^\circ$ . Heated *in vacuo*, or in  $\text{CO}_2$ , at  $440^\circ$ , gives off NO, and leaves a mixture of  $\text{RuCl}_3$  and  $\text{RuO}_3$ . Solution of the nitrosochloride is not ppd. by alkalis in the cold; but on boiling with enough alkali to combine with 3Cl, a brown gelatinous pp. of nitroso-oxide,  $\text{Ru}_2\text{O}_3\cdot 2\text{NO}\cdot 2\text{H}_2\text{O}$ , is obtained. For compounds of  $\text{RuCl}_3$  with NO and alkali chlorides, v. *Nitrosochlor-ruthenates, infra*.

**RUTHENIUM TETRACHLORIDE  $\text{RuCl}_4$ .** (*Ruthenichloride. Ruthenic chloride.*) Claus (A. 59, 234) supposed that a solution of  $\text{RuO}_3\text{H}_2$  in  $\text{HCl}$  aq contained this chloride; he also described various alkali chlor-ruthenates,  $\text{M}_2\text{RuCl}_6$ , obtained by adding alkali chlorides to the supposed solution of  $\text{RuCl}_4$ . Joly, however (C. R. 107, 994), has shown that Claus' salts contain NO; and he asserts that the compound used by C. and supposed to be  $\text{RuO}_3\text{H}_2$ , itself contained NO. Joly failed to obtain either  $\text{RuCl}_4$  or the salts  $\text{M}_2\text{RuCl}_6$ . The compounds described by C. as  $\text{M}_2\text{RuCl}_6$ , but shown by J. to be  $\text{M}_2\text{Ru(NO)Cl}_6$ , may be called *nitrosochlor-ruthenates*.

**Nitrosochlor-ruthenates,**  $\text{M}_2\text{Ru(NO)Cl}_6(\text{RuCl}_3\cdot \text{NO}\cdot 2\text{MCl})$ .  $\text{M}=\text{Am}$ , K, Na. These salts were obtained by Joly (C. R. 107, 994) by heating  $\text{RuCl}_3$  in  $\text{HNO}_3$  aq for some time and adding alkali chlorides, also by adding alkali nitrates to warm solutions of  $\text{RuCl}_3$  in  $\text{HCl}$  aq. According to Joly, the salts described by Claus as  $\text{M}_2\text{RuCl}_6$  are in reality nitrosochlor-ruthenates. These salts yield NO when heated with  $\text{CaCO}_3$ . Solutions of these salts are not ppd. by alkalis in the cold; on boiling with alkali sufficient to combine with 3Cl, a pp. of  $\text{Ru}_2\text{O}_3(\text{NO})_2\cdot 2\text{aq}$  is slowly formed (J., C. R. 108, 854). The group NO evidently forms part of the acidic radicle of the salts (cf. RUTHENIUM-AMMONIUM COMPOUNDS, p. 418).

**Potassium nitrosochlor-ruthenate,**  $\text{K}_2\text{Ru(NO)Cl}_6$ . Prepared by fusing Ru with KOH and  $\text{KNO}_3$ , dissolving in  $\text{HCl}$  aq, and evaporating somewhat till excess of KCl and  $\text{KNO}_3$  crystallise out; by evaporating the mother-liquor a mixture of  $\text{K}_2\text{RuCl}_6$  and  $\text{K}_2\text{Ru(NO)Cl}_6$  is ob-

tained, from which water dissolves the latter salt. Purified by crystallisation from water, wherein the salt is fairly soluble. Black, orthorhombic prisms; transparent when in thin crystals. Solution in water is violet-red.

Ruthenium, cyanide of, and derivatives; v. vol. ii. p. 346.

Ruthenium, hydroxides of; v. RUTHENIUM, OXIDES AND HYDRATED OXIDES OF, *infra*.

Ruthenium, hydroxychloride of,  $\text{Ru}(\text{OH})\text{Cl}_2$ . Described by Joly (C. R. 114, 291) as a solid, obtained by heating, in moist air to  $60^\circ$ , a solution of  $\text{RuCl}_2$  in absolute alcohol. Very sol. water; the deep indigo-blue solution slowly deposits  $\text{RuO}_2\text{H}_2$ .

Ruthenium, iodide of,  $\text{RuI}_3$ . This compound is formed, according to Claus (A. 59, 234), as a black pp. by adding KI to  $\text{K}_2\text{RuCl}_6\text{Aq}$ .

Ruthenium, nitroschloride of,  $\text{RuNOCl}_2$ , v. under RUTHENIUM TRICHLORIDE.

Ruthenium, nitrosopentoxide of,  $\text{Ru}_2(\text{NO})_2\text{O}_5 \cdot 2\text{H}_2\text{O}$ , v. under RUTHENIUM PENTOXIDE.

Ruthenium, oxides and hydrated oxides of. Claus described four oxides of Ru:  $\text{RuO}$ ,  $\text{Ru}_2\text{O}_3$ ,  $\text{RuO}_2$ , and  $\text{RuO}_4$ ; and the hydrated oxides  $\text{Ru}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  and  $\text{RuO}_2 \cdot 2\text{H}_2\text{O}$ . According to Debray and Joly,  $\text{RuO}$  and  $\text{Ru}_2\text{O}_3$  have not been isolated, but the oxides  $\text{Ru}_2\text{O}_3$  and  $\text{Ru}_2\text{O}_5$  exist, besides  $\text{RuO}_2$  and  $\text{RuO}_4$ . According to Joly, Claus'  $\text{RuO}_2 \cdot 2\text{H}_2\text{O}$  contains NO. It combines with O when melted in the O-H flame, with formation of  $\text{RuO}_2$ ; it is probable that  $\text{RuO}$  is formed, and then decomposed to  $\text{RuO}_2 + \text{O}_2$ .

RUTHENIUM MONOXIDE  $\text{RuO}$ . (*Ruthenous oxide*.) According to Claus (A. 59, 234), this oxide is formed, as a dark-grey, metal-like solid, by calcining  $\text{RuCl}_2$  mixed with rather more than an equivalent of  $\text{Na}_2\text{CO}_3$  in a stream of  $\text{CO}_2$ , and washing with water as long as anything dissolves. Debray and Joly (C. R. 106, 328, 1421) could not obtain this oxide.

RUTHENIUM SESQUIOXIDE  $\text{Ru}_2\text{O}_3$ . (*Ruthenous oxide*.) When Ru black is strongly heated in a Pt crucible, c.  $18.5$  p.c. O is rapidly taken up; O is then slowly absorbed till from 23 to 24 p.c. has combined, and a blue-black mass is formed. This blue-black solid is  $\text{Ru}_2\text{O}_3$ , according to Claus (A. 56, 257; 59, 234); according to D. a. J. (l.c.) it is a mixture of Ru and  $\text{RuO}_2$ .

HYDRATED RUTHENIUM SESQUIOXIDE  $\text{Ru}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  or  $\text{Ru}_2\text{O}_3\text{H}_2$ . (*Black ruthenium hydroxide*.) A black powder; prepared by ppg. solutions of  $\text{RuCl}_2$  by alkali, or by alkali carbonate, phosphate, or borate (Claus, A. 59, 234). Also ppg. from an aqueous solution of  $\text{Ru}(\text{OH})\text{Cl}_2$  (v. *Hydroxychloride, supra*). Even after washing for several days the pp. retains c. 1 p.c. alkali. Reduced, but incompletely, by H at ordinary temperature. Insol. KOHAq or NaOHAq, sl. sol.  $\text{NH}_4\text{Aq}$  (Claus, l.c.); sol. in acids. The only salts of oxyacids derived from this oxide which have been prepared are  $\text{Ru}(\text{NO}_3)_3 \cdot 3\text{KNO}_3$  and the corresponding Na salt (Claus, J. 1863, 697; Gibbs, Am. S. [2] 29, 427; 31, 63; 34, 341).

RUTHENIUM DIOXIDE  $\text{RuO}_2$ . (*Ruthenic oxide*.) Formed by strongly heating Ru sulphide, or  $\text{Ru}(\text{SO}_4)_2$ , in air (Claus, A. 59, 234).  $\text{Ru}(\text{SO}_4)_2$  is obtained by ppg.  $\text{RuCl}_2$  solution by  $\text{H}_2\text{S}$ , and oxidising the pp. by  $\text{HNO}_3$ .  $\text{RuO}_2$  is also formed, as a crystalline sublimate, by roasting osm-

iridium containing Ru in a porcelain tube (Fremy, A. Ch. [3] 44, 385). Also obtained by strongly heating finely divided Ru for some time in a stream of O (D. a. J., A. Ch. [3] 56, 385; C. R. 83, 927; 87, 441). The whole of the Ru is not converted into  $\text{RuO}_2$ , but some metal remains unoxidised (D. a. J., C. R. 106, 1494). At a very high temperature  $\text{RuO}_2$  is formed, and at a lower temperature this is resolved into  $\text{RuO}_3$  and O (D. a. J., C. R. 80, 457; D. a. J., C. R. 106, 1421). D. a. J. (C. R. 106, 328) obtained  $\text{RuO}_2$ , partly amorphous and partly crystalline, by heating  $\text{RuO}$  to  $107^\circ$ ; also by heating  $\text{Ru}_2\text{O}_3$  to  $440^\circ$ .

Dark-violet, quadric crystals; isomorphous with rutile (Fremy, l.c.; D. a. J., l.c.). S.G. 7.2 (D. a. J., A. Ch. [3] 56, 385). Insol. acids, sol. molten KOHAq. Easily reduced by H. The only salt of an oxyacid corresponding with  $\text{RuO}_2$ , which has been isolated is  $\text{Ru}(\text{SO}_4)_2$  (Claus, l.c.).

HYDRATED RUTHENIUM DIOXIDE  $\text{RuO}_2 \cdot 5\text{H}_2\text{O}$  or  $\text{RuO}_2\text{H}_2 \cdot 3\text{H}_2\text{O}$ . The existence of this compound is doubtful. Claus (A. 59, 234) gave this composition to the gelatinous, yellow-brown pp. formed by decomposing  $\text{K}_2\text{RuCl}_6\text{Aq}$  by  $\text{Na}_2\text{CO}_3$ ; but Joly has shown that Claus'  $\text{K}_2\text{RuCl}_6$  contains NO (cf. RUTHENIUM TETRACHLORIDE, p. 415). Claus also obtained hydrated  $\text{RuO}_2$  by evaporating  $\text{Ru}(\text{SO}_4)_2\text{Aq}$  with KOHAq; but as the sulphate employed was obtained by oxidising Ru sulphide by  $\text{HNO}_3$ , it may have contained NO. Joly (C. R. 107, 994) gives the formula  $\text{Ru}_2\text{O}_3(\text{NO})_2 \cdot 2\text{H}_2\text{O}$  to the brown gelatinous pp. formed by boiling  $\text{Ru}(\text{NO})\text{Cl}_2$  or  $\text{K}_2\text{Ru}(\text{NO})\text{Cl}_2$  with KOHAq or  $\text{K}_2\text{CO}_3\text{Aq}$ . It seems probable that Claus'  $\text{RuO}_2 \cdot 5\text{H}_2\text{O}$  is the same as the nitroso-compound obtained by Joly (cf. *infra Hydrated nitroso-pentoxide*).

RUTHENIUM PENTOXIDE  $\text{Ru}_2\text{O}_5 (= \text{RuO}_2 \cdot \text{RuO}_3)$ . When  $\text{RuO}_2\text{Aq}$  stands for some time in a closed vessel, a black pp. settles down and a black crystalline crust forms on the sides of the vessel, while O is set free and escapes when the vessel is opened. The composition of the pp. and crystalline crust after drying at  $100^\circ$  is given by Debray a. Joly as  $\text{Ru}_2\text{O}_5$  (C. R. 106, 328). This oxide is also obtained by allowing a dilute solution of a ruthenate to stand for a long time, or by adding a dilute acid to such a solution.  $\text{Ru}_2\text{O}_5$  dissolves in  $\text{HClAq}$ , giving off Cl; heated to  $360^\circ$   $\text{Ru}_2\text{O}_5$  is formed.

Hydrated nitroso-pentoxide  $\text{Ru}_2\text{O}_5(\text{NO})_2 \cdot 2\text{H}_2\text{O}$ . A black solid, formed by boiling  $\text{Ru}(\text{NO})\text{Cl}_2$  or  $\text{K}_2\text{Ru}(\text{NO})\text{Cl}_2$  (v. *Nitroschloride*, and *Nitroschlor-ruthenates*, p. 415) with sufficient alkali or alkaline carbonate to combine with 3Cl, and drying the pp. at  $150^\circ$  (Joly, C. R. 103, 854). Slowly decomposes when heated to  $360^\circ$  in  $\text{CO}_2$ , giving  $\text{Ru}_2\text{O}_5$ ; above  $440^\circ$  decomposes violently, giving off N oxides; reduced by H below  $100^\circ$ , giving off  $\text{NH}_3$ . Sol. in acids, forming nitroso-salts.

RUTHENIUM NONOXIDE  $\text{Ru}_3\text{O}_8 (= 3\text{RuO}_2 \cdot \text{RuO}_3)$ . This composition was given by D. a. J. (C. R. 106, 328) to the black, lustrous, crystalline crust obtained by heating  $\text{RuO}_2\text{Aq}$  to  $100^\circ$ . The same oxide is formed by heating  $\text{Ru}_2\text{O}_5$  to  $860^\circ$ . Heated to  $440^\circ$  this oxide gives amorphous  $\text{RuO}_2$  and O.

RUTHENIUM TRI-OXIDE  $\text{RuO}_3$ . (*Ruthenic anhydride*.) This oxide has not been isolated,

but salts derived from it are known.  $\text{RuO}_3$  is the hypothetical anhydride of ruthenic acid ( $\text{H}_2\text{RuO}_4$ ), which has not been isolated. For the salts corresponding with this oxide *v. Ruthenates*, under RUTHENIUM, SALTS OF OXYACIDS OF, *infra*.

**RUTHENIUM HEPTOXIDE  $\text{Ru}_2\text{O}_7$ .** (*Per-ruthenic anhydride*.) This oxide, the hypothetical anhydride of the non-isolated per-ruthenic acid ( $\text{H}_2\text{RuO}_7$ ), has not been prepared. For the salts corresponding with this oxide *v. Per-ruthenates*, under RUTHENIUM, SALTS OF OXYACIDS OF, *infra*.

**RUTHENIUM TETROXIDE  $\text{RuO}_4$ .** (Sometimes called *per-ruthenic acid*, and frequently *ruthenic acid*.) Mol. w. 165.24. V.D. 83.3 at  $100^\circ$  and 106 mm. pressure (Debray a. Joly, *C. R.* 106, 328).

**Formation.**—1. By passing Cl into a solution of the product of fusing Ru with KOH and  $\text{KNO}_3$ .—2. By the action of  $\text{KClO}_4$  and  $\text{HCl}$ , not *aqua regia*, on  $\text{K}_2\text{RuCl}_4\text{Aq}$  (Claus, *A.* 59, 234).—3. By heating finely divided Ru in a stream of O to c.  $1000^\circ$ , and cooling rapidly by means of ice. If the temperature is allowed to fall slowly the  $\text{RuO}_4$  formed decomposes explosively at c.  $108^\circ$  (Debray a. Joly, *C. R.* 106, 100).

**Preparation.**—A mixture of 1 part finely divided Ru, with 8 parts KOH and 1 part  $\text{KNO}_3$ , is heated to dull redness in a silver crucible till fused; the product, when cold, is dissolved in 16 parts water; the solution is placed in a tubulated retort connected, by a long tube, with a very well cooled receiver (the connecting tube being also cooled), and a rapid stream of Cl is passed into the solution; a considerable amount of heat is produced, and  $\text{RuO}_4$  passes over and solidifies in the receiver (Dewille a. Debray, *A. Ch.* [5] 4, 537). To free the preparation from water D. a. J. (*C. R.* 106, 328) place it in a tube with fused  $\text{CaCl}_2$ , contract the tube in the middle, pump out the air, and seal off the tube. The  $\text{RuO}_4$  slowly sublimates into the upper part, which is then separated from the rest. The  $\text{RuO}_4$  is finally distilled *in vacuo* into tubes which have been very carefully cleansed from all traces of organic matter, and dried by heating to redness in a stream of H.  $\text{RuO}_4$  may be obtained in well-formed crystals by subliming *in vacuo* at the ordinary temperature.

**Properties.**—(D. a. J., *C. R.* 106, 328.) Golden yellow crystals, melting at  $25.5^\circ$  to an orange-red liquid, which solidifies slowly to a vitreous solid. Smell resembles that of ozone; the vapour causes coughing, but does not affect the eyes (Claus, *J. pr.* 80, 282). Sublimes at 3 to 4 mm. pressure on the slightest rise of temperature; the vapour is golden yellow. Decomposes at  $106^\circ$ – $107^\circ$  without boiling. The vapour-pressure of the crystals is almost nil at  $0^\circ$ , 20 mm. at  $42^\circ$ , and 182 mm. at  $100.8^\circ$ . May be distilled in water-vapour containing Cl or  $\text{HClO}_4$ . Gradually reduced to  $\text{RuO}_3$  by sunlight (Joly, *C. R.* 113, 693). Dissolves in water, forming a golden-yellow solution, which gradually decomposes with p.pn. of  $\text{Ru}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ .  $\text{RuO}_4$  attacks Hg, and slowly acts on glass.  $\text{RuO}_4$  does not form corresponding salts, either by reacting with acids or alkalis. Moist  $\text{RuO}_4$  is very easily reduced, e.g. by contact with paper.

**Reactions.**—1. Decomposed by heat; no action below  $108^\circ$ ; at  $107^\circ$  sudden decomposition occurs, with a smoky flame and formation of amorphous  $\text{RuO}_3$  on the walls of the vessel, and crystalline  $\text{RuO}_4$  from the part that has melted (D. a. J., *l.c.*). According to D. a. J. (*C. R.* 106, 100),  $\text{RuO}_4$  is formed when O is passed over spongy Ru at c.  $1000^\circ$ , and the product is rapidly cooled. If cooling is allowed to take place slowly the  $\text{RuO}_4$  decomposes at c.  $108^\circ$ .—2. Dissolves in water; solution keeps unchanged for some time, but slowly deposits  $\text{Ru}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ . Decomposition is more rapid at higher temperatures; at  $100^\circ$   $\text{Ru}_2\text{O}_3 \cdot x\text{H}_2\text{O}$  is formed (D. a. J., *l.c.*).—3. Solution in water, or moist  $\text{RuO}_4$ , is quickly reduced by alcohol and several other organic compounds (Claus, *J. pr.* 80, 282).—4. With solutions of alkalis forms ruthenates and per-ruthenates, with evolution of O. Alcoholic solution of potash ppts.  $\text{Ru}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ .—5. Heated with hydrochloric acid, Cl is given off and  $\text{RuCl}_3$  formed in solution.—6. Hydrogen sulphide gradually throws down a black pp. of an oxysulphide, from  $\text{RuO}_4\text{Aq}$  (Claus, *l.c.*).

**Ruthenium, oxyacids of.** No oxyacid of Ru has been isolated, but some salts of the hypothetical acids  $\text{H}_2\text{RuO}_4$  and  $\text{H}_2\text{RuO}_7$  are known (*v. RUTHENIUM, SALTS OF OXYACIDS OF, infra*).

**Ruthenium, oxysulphide of.** A current of  $\text{H}_2\text{S}$  passed into  $\text{RuO}_4\text{Aq}$  slowly ppts. all the Ru as a black substance, which is said by Claus (*J. pr.* 80, 282) to be an oxysulphide, whose composition varies according to the quantity of  $\text{H}_2\text{S}$  passed in. The pp. suddenly glows when dried at  $100^\circ$ , and burns, giving off  $\text{SO}_2$ .

**Ruthenium, salts of.** Very few salts are known obtained by replacing the H of oxyacids by Ru. The double nitrites  $\text{Ru}(\text{NO})_2 \cdot 3\text{MNO}_3$ , where M = K or Na, are the only salts which have been prepared corresponding with  $\text{Ru}_2\text{O}_7$ ; and  $\text{Ru}(\text{SO}_3)_2$  is the only salt of  $\text{RuO}_3$  which has been isolated; the double sulphite  $\text{RuSO}_3 \cdot \text{K}_2\text{SO}_3$  corresponds with  $\text{RuO}_4$ .

**Ruthenium, salts of oxyacids of.** A few salts of the hypothetical acid  $\text{H}_2\text{RuO}_4$ , and two salts of the hypothetical acid  $\text{H}_2\text{RuO}_7$ , have been isolated.

**RUTHENATES,  $\text{M}^1\text{RuO}_4$ .** Salts of hypothetical  $\text{H}_2\text{RuO}_4$  (formerly called *ruthenites*). These salts are formed by heating Ru, or an oxide of Ru, with an oxide, hydroxide, nitrate, or chlorate of an alkali metal (Claus, *A.* 56, 257; 59, 234), or of an alkaline earth metal (Dewille a. Debray, *A. Ch.* [3] 56, 385). Ruthenates in solution are easily reduced by organic bodies, with p.pn. of black  $\text{Ru}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ ; acids added to conc. solutions form per-ruthenates,  $\text{M}^1\text{RuO}_7$ .

**Barium ruthenate  $\text{BaRuO}_4$ .** Obtained by adding  $\text{RuO}_4$  to  $\text{BaOaq}$ . The solution is at first green, probably from formation of per-ruthenate; a black pp. is thrown down, which soon changes to the cinnabar-coloured crystalline Ba salt. This salt is also formed by adding  $\text{BaCl}_2\text{Aq}$  to a solution of the K salt (Debray a. Joly, *C. R.* 106, 1491).

**Potassium ruthenate  $\text{K}_2\text{RuO}_4\text{aq}$**  (D. a. J., *l.c.*). 50 g.  $\text{RuO}_4$ , melted under water, are slowly added to 70 g. KOH in 500 c.c. water at  $60^\circ$ ; temperature is kept at  $60^\circ$  until the evolution of O has ceased, when the solution is evaporated *in vacuo*; long, black, orthorhombic prisms, reflecting green light, are formed (for

crystalline measurements v. D. a. J. (l.c. p. 1497). After drying *in vacuo*, the crystals absorb moisture and CO<sub>2</sub> from the air. Unchanged at 106° *in vacuo*; loses H<sub>2</sub>O at 200°, and may then be heated to 400° without decomposition. Very sol. water; solution is orange yellow; it soon decomposes in air, depositing Ru<sub>2</sub>O<sub>3</sub>·xH<sub>2</sub>O, and probably forming KRuO<sub>4</sub>. Organic bodies dipped into the solution become black from deposition of Ru<sub>2</sub>O<sub>3</sub>·3H<sub>2</sub>O. Acids hasten formation of KRuO<sub>4</sub> and Ru<sub>2</sub>O<sub>3</sub>; from conc. K<sub>2</sub>RuO<sub>4</sub> acids ppt. KRuO<sub>4</sub>, which decomposes to Ru<sub>2</sub>O<sub>3</sub> and RuO<sub>2</sub> (D. a. D., C. R. 83, 927).

The *magnesium, silver, and strontium* salts are obtained by adding MgCl<sub>2</sub>Aq, AgNO<sub>3</sub>Aq, and SrCl<sub>2</sub>Aq respectively to K<sub>2</sub>RuO<sub>4</sub>Aq. The *sodium* salt has not been isolated; it cannot be separated from excess of soda.

**PER-RUTHENATES, MRuO<sub>4</sub>.** Salts of hypothetical HRuO<sub>4</sub> (formerly called *ruthenates*). Obtained by the action of Cl on ruthenates, or of acids on conc. solutions of ruthenates. Alkalis produce ruthenates from solutions of per-ruthenate.

**Potassium per-ruthenate** KRuO<sub>4</sub> (Dévillé a. Debray, C. R. 83, 927). 50 g. RuO<sub>3</sub>, melted under water, are slowly added to 60 g. KOH in 250 c.c. water at 60°; O is evolved, and the solution becomes green; after O ceases to come off, the liquid is allowed to cool in a closed vessel; the cold (red) liquid, which contains K<sub>2</sub>RuO<sub>4</sub>, is poured off, and the crystals of KRuO<sub>4</sub> that adhere to the sides of the vessel are dried *in vacuo* on an unglazed porcelain plate. Black, opaque, quadratic pyramids (for crystallographic measurements v. D. a. J., C. R. 106, 1496). Unchanged in air after drying *in vacuo*; decomposes suddenly at 440°, giving off O (? with formation of K<sub>2</sub>RuO<sub>4</sub> and RuO<sub>2</sub>). Cl reacts in the cold to form RuO<sub>4</sub> and KCl. Slightly sol. water; solution is blackish-green and soon decomposes, KOH being formed. Alkalis added to K<sub>2</sub>RuO<sub>4</sub>Aq produce K<sub>2</sub>RuO<sub>4</sub>Aq, with evolution of O.

The *sodium* salt, NaRuO<sub>4</sub>aq, has been isolated; it forms black crystals. Addition of chlorides of alkaline earths to solution of KRuO<sub>4</sub>, or NaRuO<sub>4</sub>, ppts. M<sup>II</sup>RuO<sub>4</sub>, not M<sup>IV</sup>(RuO<sub>4</sub>)<sub>2</sub>, and the solutions contain RuO<sub>4</sub>.

**Ruthenium, sulphides of.** No sulphide of Ru has been isolated with certainty. Claus could not obtain a sulphide by heating Ru with S in CO<sub>2</sub> (A. 56, 257; 59, 234). The pps. formed by H<sub>2</sub>S in solutions of Ru compounds vary in composition, and contain free S. By ppg. RuCl<sub>3</sub> solution by H<sub>2</sub>S, and heating the solid in CO<sub>2</sub>, S and H<sub>2</sub>O are given off, and a greyish-black metal-like substance remains, which is perhaps Ru<sub>2</sub>S<sub>3</sub> (C. l.c.). The pp. which H<sub>2</sub>S produces in RuO<sub>4</sub>Aq is probably an *oxysulphide* (q. v.). The mineral *laurite*, from Borneo and Oregon, contains Ru<sub>2</sub>S<sub>3</sub> with Os sulphide (Wöhler, A. 139, 116; 191, 374). M. M. P. M.

#### RUTHENIUM-AMMONIUM COMPOUNDS.

[*Ruthenamines. Ammoniacal ruthenium bases.*] These compounds have not been obtained by treating Ru chlorides with NH<sub>3</sub>Aq. The starting-point for the compounds described by Claus was RuCl<sub>3</sub>·2NH<sub>3</sub>Cl. By treatment with NH<sub>3</sub>Aq, Claus obtained RuCl<sub>3</sub>·4NH<sub>3</sub>aq, and from this he prepared various salts RuX<sub>3</sub>·4NH<sub>3</sub>,

where X = monovalent acidic radicle (N. Petersb. Acad. Bull. 1, 97; 2, 158). By evaporating a solution of the base Ru(OH)<sub>3</sub>·4NH<sub>3</sub> *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, Claus obtained a new base, to which he gave the formula Ru(OH)<sub>3</sub>·2NH<sub>3</sub>·4aq; he did not prepare any salts of this base. Joly (C. R. 107, 994) found that Claus' RuCl<sub>3</sub>·2NH<sub>3</sub>Cl is a nitroso-compound, and has the composition RuCl<sub>3</sub>·NO·2NH<sub>3</sub>Cl. Joly also showed (C. R. 108, 1300) that Claus' RuCl<sub>3</sub>·4NH<sub>3</sub> has the composition RuCl<sub>3</sub>·NO·OH·4NH<sub>3</sub>, and that the salts obtained by Claus belong to the form RuX<sub>3</sub>·NO·OH·4NH<sub>3</sub>. Whether the base described by Claus as Ru(OH)<sub>3</sub>·2NH<sub>3</sub> contains NO or not has not been determined; it is described here provisionally.

The nomenclature adopted in this article must be looked on as only provisional.

#### NITROSO-RUTHENI-DIAMMINES,

X.NO.Ru(NH<sub>2</sub>.NH<sub>2</sub>)<sub>2</sub>; R may or may not be the same as X. (Joly, C. R. 108, 1300; 111, 969.) Described by Claus as *ammonium ruthenoso-diammonium compounds*, N<sub>2</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>Ru.X<sub>2</sub>, or *ruthenoso-diammines*, Ru(NH<sub>2</sub>.NH<sub>2</sub>)<sub>2</sub>X<sub>2</sub>.

#### Series I. Hydroxy-compounds,

OH.NO.Ru(NH<sub>2</sub>.NH<sub>2</sub>)<sub>2</sub>R<sub>2</sub>. The *chloride*, R = Cl, was obtained (Joly, C. R. 108, 1300) by boiling Ru(NO)Cl<sub>3</sub> (described under RUTHENIUM TRICHLORIDE, p. 415) with excess of NH<sub>3</sub>Aq, until the liquid became golden yellow, and deposited orange-yellow crystals of the salt. The *bromide* R = Br, and *iodide* R = I, were prepared similarly. The *carbonate* R =  $\frac{1}{2}$ CO<sub>3</sub>, *nitrate* R = NO<sub>3</sub>, and *sulphate* R =  $\frac{1}{2}$ SO<sub>4</sub>, were prepared by the reaction of the chloride with Ag salts. By reacting on the chloride with moist Ag<sub>2</sub>O, Joly obtained a strongly alkaline liquid which probably contained the *hydroxide*, R = OH. The chloride forms a *double compound* with PtCl<sub>4</sub>.

#### Series II. Chloro-compounds,

Cl.NO.Ru(NH<sub>2</sub>.NH<sub>2</sub>)<sub>2</sub>R<sub>2</sub> (Joly, C. R. 111, 969). The *chloride*, R = Cl, was obtained by dissolving the hydroxy-chloride in much HClAq, evaporating, and crystallising from boiling water; it combines with PtCl<sub>4</sub>. The *bromide* and *iodide*, R = Br and I, were obtained similarly to the chloride.

#### Series III. Nitrate-compounds,

NO<sub>3</sub>.NO.Ru(NH<sub>2</sub>.NH<sub>2</sub>)<sub>2</sub>R<sub>2</sub>. The *nitrate*, R = NO<sub>3</sub>, was formed by the action of AgNO<sub>3</sub>Aq, or boiling HNO<sub>3</sub>Aq, on the chloro-chloride (J., l.c.).

#### Series IV. Sulphato-compounds,

SO<sub>4</sub>.2[NO.Ru(NH<sub>2</sub>.NH<sub>2</sub>)<sub>2</sub>R<sub>2</sub>]. Two *sulphates*, the normal salt where R =  $\frac{1}{2}$ SO<sub>4</sub>, and the acid salt 2(SO<sub>4</sub>.2[NO.Ru(NH<sub>2</sub>.NH<sub>2</sub>)<sub>2</sub>R<sub>2</sub>].H<sub>2</sub>SO<sub>4</sub>, were obtained by the action of H<sub>2</sub>SO<sub>4</sub>Aq on the chloro-chloride.

These compounds give off NH<sub>3</sub> when heated in KOHAq, and separate Ru nitroso-hydroxide Ru(OH).NO, from which nitroso-salts are obtained by the action of acids.

??RUTHENOS-AMMINES, Ru(NH<sub>2</sub>X)<sub>3</sub>, or *ruthenos-diammonium compounds*, NH<sub>2</sub>(NH<sub>2</sub>)Ru.X<sub>2</sub>. The only compound of this class which has been isolated is the *hydroxide*, Ru(NH<sub>2</sub>.OH)<sub>3</sub>·4aq, obtained by Claus (N. Petersb. Acad. Bull. 1, 97; 2, 158) by evaporating, over H<sub>2</sub>SO<sub>4</sub> *in vacuo*, a solution of the base to which he gave the formula Ru(NH<sub>2</sub>.NH<sub>2</sub>.OH)<sub>3</sub>. As the compound from which Claus obtained the supposed ruthenos-ammine hydroxide has been found

to contain NO, it is probable that the product of evaporation was also a nitroso-compound.

M. M. P. M.

**RUTIN**  $C_{28}H_{34}O_{15}$ . [above 190°]. S. 58 at 100°. S. (boiling alcohol) 20. S. (ether) 29. Extracted by alcohol or HOAc from the leaves of the garden rue (*Ruta graveolens*) (Weiss, *Pharm. Centr.* 1842, 903; Bornträger, *A.* 53, 885; Förster, *B.* 15, 217). Occurs also in capers, the flower-buds of *Capparis spinosa* (Rochleder a. Hlasiwetz, *A.* 82, 197; 96, 123; Zwenger a. Dronke, *A.* 123, 145), in safflower (Stein, *J. pr.* 58, 399; 88, 280), in rose leaves (Fihol, *J.* 1863, 594), and in the leaves of the buck-

wheat (*Polygonum Fagopyrum* (Schunck, *O. J.* 53, 262). Crystallises from water in pale-yellow needles (containing 8aq). Sol. alkalis, forming a yellow solution, from which it is reprecipitated by acids. FeCl<sub>3</sub> gives a dark-green colour. Lead acetate added to its alcoholic solution forms a yellow pp. Pb<sub>2</sub>C<sub>12</sub>H<sub>10</sub>O<sub>18</sub>. Does not reduce Fehling's solution. Decomposed by boiling dilute H<sub>2</sub>SO<sub>4</sub> into quercetin (1 mol.) and isodulcitol (3 mols.).

**RUTYL**. A name sometimes used for decyl C<sub>10</sub>H<sub>19</sub>O or decyl C<sub>10</sub>H<sub>21</sub>.

**RUTYLENE** v. DECINENE.

**RUTYLIDENE** v. HENDEKINENE.

## S

### SACCHARIC ACID C<sub>6</sub>H<sub>10</sub>O<sub>7</sub>, i.e.

CO<sub>2</sub>H.CH(OH).CH(OH).CH(OH).CH(OH).CO<sub>2</sub>H. Mol. w. 210. Formed by the action of nitric acid (6 pts. of S.G. 1.15) on dextrose (glucose), and therefore on cane sugar and on milk sugar (Scheele, *Opuscula*, ii. 203; Trommsdorff, *A.* 8, 36; Guérin-Varry, *A. Ch.* [2] 49, 230; 52, 318; 65, 332; Erdmann, *A.* 21, 1; Hess, *A.* 26, 1; Thauloff, *A.* 27, 113; Liebig, *A.* 30, 313; 113, 1; Heintz, *P.* 61, 315; 105, 211; 106, 93; 111, 265, 291; *A.* 51, 185; Tollens, *B.* 21, 2149). Formed also by oxidation of dextrin, maltose, and dextrose by Br, and subsequent addition of ZnCO<sub>3</sub> (Herzfeld, *A.* 220, 352), and by the action of Br on glycuronic acid (Thierfelder, *B.* 19, 3148).

**Preparation**.—1. Dextrose (5 g.) is evaporated with HNO<sub>3</sub> (30 c.c. of S.G. 1.15) to a thick syrup. The syrup is dissolved in water (20 c.c.) and neutralised with K<sub>2</sub>CO<sub>3</sub>; HOAc is then added and the solution evaporated until the acid K salt crystallises out (Tollens, *A.* 249, 218).—2. Starch (100 g.) is ground up with water (100 c.c.), poured into HNO<sub>3</sub> (500 c.c. of S.G. 1.15), and heated on the water-bath till red fumes begin to come off. The temperature is then lowered and kept at 65° until syrupy. The product is converted as above into the acid K salt (20 g.), which is dissolved in water, neutralised with ammonia, and pptd. by AgNO<sub>3</sub>. The Ag salt is then decomposed by HCl (Sohst a. Tollens, *A.* 245, 4).

**Properties**.—Brittle deliquescent mass, v. sol. water and alcohol, v. sl. sol. ether. Dextrorotatory, [α]<sub>D</sub> varying from 8° to 38°. Reduces auric chloride and ammoniacal AgNO<sub>3</sub> (forming a mirror) but not Fehling's solution (Kilian, *B.* 14, 2529).

**Reactions**.—1. Oxidised by HNO<sub>3</sub> to dextro-tartaric, racemic, and oxalic acids.—2. Potash at 250° yields acetic and oxalic acids.—3. PCl<sub>5</sub> forms chloromucic acid C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>O<sub>6</sub> [260°] (Bell, *B.* 12, 1272).—4. Boiling dilute (30 p.a.) HCl aq forms dehydromucic acid (S. a. T.; Schrötter, *M.* 9, 442).—5. HIAq and P at 150° forms some adipic acid (De la Motte, *B.* 12, 1572).—6. The ammonium salt decomposes at 160° into CO<sub>2</sub>, NH<sub>3</sub>, and pyrrole (Bell a. Lapper, *B.* 10, 1961). The ethylamine salt yields, in like manner, ethyl-pyrrole.—7. Phenyl-hydrazine acetate at 100° forms C<sub>6</sub>H<sub>4</sub>O<sub>4</sub>(CO<sub>2</sub>N<sub>2</sub>H<sub>2</sub>Ph)<sub>2</sub> a

yellowish substance [210°], insol. water, alcohol, and ether; not decomposed by alcoholic potash (Maquenne, *B.* [2] 48, 721).

**Salts**.—KHA': trimetric crystals; *a:b:c* = 1.763:1.234. S. 1:1 at 7°.—KA'': crystalline crusts, v. sol. water.—(NH<sub>4</sub>)HA'. S. 1:22 at 15°; 2:4 at 100°. Four-sided prisma.—BaA': minute crystals, v. sl. sol. water.—BaA'' 3aq: amorphous.—CaA' aq.—SrA' 1½aq.—MgA' 3aq: crystalline, m. sol. hot water.—ZnA' aq.—CdA'.—PbA'.—Pb<sub>2</sub>C<sub>12</sub>H<sub>10</sub>O<sub>18</sub>.—Pb<sub>2</sub>C<sub>12</sub>H<sub>10</sub>O<sub>18</sub>.—Pb<sub>2</sub>C<sub>12</sub>H<sub>10</sub>O<sub>18</sub>.—Pb<sub>2</sub>Cl<sub>2</sub>A'.—Bi<sub>2</sub>C<sub>12</sub>H<sub>10</sub>O<sub>18</sub> 2aq.—AgA': white pp.

**Ethyl ether** Et<sub>2</sub>A'. Crystalline mass, v. sol. water and alcohol.—(Et<sub>2</sub>A')<sub>2</sub>CaCl<sub>2</sub>. Prisms, v. sol. water, sl. sol. alcohol, insol. ether.

**Tetra-acetyl derivative of the ethyl ether** C<sub>6</sub>H<sub>4</sub>Ac<sub>4</sub>Et<sub>2</sub>O<sub>6</sub>. [61°]. Monoclinic tables (from alcohol), insol. Ag, v. e. sol. hot alcohol.

**Anhydride** C<sub>6</sub>H<sub>4</sub>O<sub>6</sub>, i.e.

CH(OH) < CH(OH) > CH<sub>2</sub>CH(OH).CO<sub>2</sub>H. *Saccharolactone*. [132°]. Formed by allowing syrupy saccharic acid to stand over H<sub>2</sub>SO<sub>4</sub> for some days (Sohst a. Tollens, *A.* 245, 5). Thin plates (from water). Yields pyromucic acid on heating. Reduced in acid solution by treatment with sodium-amalgam to glycuronic acid CO<sub>2</sub>H.CH(OH).CH(OH).CH(OH).CH(OH).CHO (Fischer a. Piloty, *B.* 23, 937; 24, 521).

**Di-acetyl derivative of the double anhydride** C<sub>10</sub>H<sub>10</sub>O<sub>8</sub>, i.e.

CH(OAc).CH<sub>2</sub>O.CO [188°]. Formed from Ac<sub>2</sub>O, acid potassium saccharate, and H<sub>2</sub>SO<sub>4</sub> (Maquenne, *B.* [2] 48, 720; cf. Baltzer, *B.* [2] 10, 263; *A.* 149, 238). White plates, v. sl. sol. alcohol and ether.

**Amide** C<sub>6</sub>H<sub>4</sub>O<sub>6</sub>(NH<sub>2</sub>)<sub>2</sub>. Amorphous powder

**Isosaccharic acid** C<sub>6</sub>H<sub>10</sub>O<sub>7</sub>. [185°]. [α]<sub>D</sub> = 46° at 20°. Formed by careful oxidation of glucosamine hydrochloride by dilute HNO<sub>3</sub> (S.G. 1.2) (Tiemann, *B.* 17, 246; 19, 1258, 1273). Trimetric crystals (from water), v. sol. water and alcohol, sl. sol. ether. Dextrorotatory. Converted by heat into CO<sub>2</sub> and pyromucic acid. Reduced by HI to adipic acid. Heated in a current of dry HCl it yields furfural (aa')-dicarboxylic acid. PCl<sub>5</sub> forms C<sub>6</sub>H<sub>4</sub>ClO(CO<sub>2</sub>H)<sub>2</sub> which yields Et<sub>2</sub>A' [40°].

**KHA''** 3aq: v. sol. water.—(NH<sub>4</sub>)<sub>2</sub>A''.—BaA''.—CaA''.—SrA''.—PbA'' 2aq.—CuA''.—AgA''.

**Ethyl ether Et.A''**. [78°]. (250°). [α]<sub>D</sub> = +85.5°. Needles, v. sol. water. Yields a tetra-acetyl derivative C<sub>8</sub>H<sub>4</sub>(OAc)<sub>4</sub>(CO<sub>2</sub>Et)<sub>2</sub> [47°] v. sol. water and alcohol.

**Amide of the anhydride**

C<sub>8</sub>H<sub>4</sub>O(OH)<sub>2</sub>(CONH<sub>2</sub>)<sub>2</sub> [226°]. [α]<sub>D</sub> = 7.2°.

**Anilide of the anhydride**. [231°].

**Acetyl derivative** C<sub>8</sub>H<sub>4</sub>(OAc)<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub> aq. [101°]. Needles (from water).

**Parasaccharic acid** C<sub>8</sub>H<sub>10</sub>O<sub>8</sub>. Formed, together with glycyrrhetin, by boiling glycyrrhizin with dilute H<sub>2</sub>SO<sub>4</sub> (Habermann, C. G. 1880, 253). Hygroscopic mass, sol. water and alcohol. Its salts are amorphous.

**Metasaccharic acid** C<sub>8</sub>H<sub>10</sub>O<sub>8</sub>. The salt CaA'' aq, got by boiling an aqueous solution of the dianhydride with CaCO<sub>3</sub>, forms crystals, sl. sol. water. KA' and Ag<sub>2</sub>C<sub>8</sub>H<sub>10</sub>O<sub>8</sub> have also been prepared (Fischer, B. 23, 2321). Solutions of metasaccharates turn deep red when exposed to air.

**Dilactone** C<sub>8</sub>H<sub>6</sub>O<sub>6</sub> i.e.

CH(OH).CH(O).CO

CO . O.CH—CH(OH) .

**l-Mannosaccharic**

**acid**. [68°]. S. 5.5 at 15°. [α]<sub>D</sub> = -20.2° (Fischer, B. 24, 541). Formed by oxidation of arabinose-carboxylic (mannonic) acid C<sub>8</sub>H<sub>12</sub>O<sub>7</sub>, by digesting its lactone with HNO<sub>3</sub> (S.G. 1.2) for 24 hours at 50° (Kiliani, B. 20, 341, 2710; 21, 1422). Long colourless needles (containing 2aq), sl. sol. alcohol, insol. ether. Readily reduces Fehling's solution. Reduced by HI to *n*-adipic acid. Sodium-amalgam reduces it to mannite. Phenyl hydrazine hydrochloride and sodium acetate solution in the cold form CH(OH).CH(OH).CO . O.CH.CH(OH).CO.N<sub>2</sub>H<sub>4</sub>Ph [192°] crystallising in minute plates (containing 3aq), v. e. sol. hot water. Phenyl hydrazine hydrochloride and boiling sodium acetate solution forms C<sub>8</sub>H<sub>4</sub>(OH)<sub>2</sub>(CO.N<sub>2</sub>H<sub>4</sub>Ph)<sub>2</sub> crystallising in minute plates [213°], v. sl. sol. water.

**Di-acetyl derivative of the dilactone**

CH(OAc).CH(O).CO

CO.O—CH—CH(OAc) [155°].

Formed by adding a few drops of H<sub>2</sub>SO<sub>4</sub> to a mixture of the dilactone and Ac<sub>2</sub>O (Kiliani, B. 22, 524). Prisms, v. sol. hot HOAc.

**Amide** C<sub>8</sub>H<sub>4</sub>(OH)<sub>2</sub>(CO.NH<sub>2</sub>)<sub>2</sub> [190°]. Formed from the lactone and NH<sub>4</sub>Aq. Monoclinic tables.

**Dextro-metasaccharic acid. d-Mannosaccharic acid** C<sub>8</sub>H<sub>10</sub>O<sub>8</sub>. Salts.—CaA'': crystalline powder.—BaA'': minute tables, m. sol. water.—SrA'':—CdA'': minute tables, v. sl. sol. water.

**Lactone** C<sub>8</sub>H<sub>6</sub>O<sub>6</sub>. [180°–190°]. [α]<sub>D</sub> = 20.2° at 29°. Formed by oxidation of mannose, of mannite, or of *d*-mannonic acid by HNO<sub>3</sub> (S.G. 1.2) at 50° (Fischer a. Wirthle, B. 24, 539; Esterfield, C. J. 59, 306). Long needles (from alcohol or water), v. sol. hot water. Readily reduces Fehling's solution. Turns yellow on boiling with potash. Phenyl-hydrazine acetate in the cold forms CH(OH).CH(OH).

CO.O—CH.CH(OH).CON<sub>2</sub>H<sub>4</sub>Ph [191°],

while at 100° it forms C<sub>8</sub>H<sub>4</sub>(OH)<sub>2</sub>(CO.N<sub>2</sub>H<sub>4</sub>Ph)<sub>2</sub> [212°], almost insol. hot water.

**Amide** C<sub>8</sub>H<sub>12</sub>N<sub>2</sub>O<sub>6</sub>. [189°]. Formed from the lactone and NH<sub>4</sub>Aq in the cold. Crystals.

**Inactive metasaccharic acid** C<sub>8</sub>H<sub>10</sub>O<sub>8</sub>. *i-Mannosaccharic acid*. The salts of this acid greatly resemble those of the preceding acid.

**Lactone** C<sub>8</sub>H<sub>6</sub>O<sub>6</sub>. [c. 190°]. Formed by mixing equal parts of the dextro- and laevo-lactones in aqueous solution. Formed also by oxidising *i*-mannonic lactone (E. Fischer a. Stanley Smith, B. 23, 2622; 24, 544). The aqueous solution is inactive to light, and gradually becomes acid on standing. Phenyl-hydrazine acetate reacts, forming in the cold CH(OH).CH(OH).

CO.O—CH.CH(OH).CON<sub>2</sub>H<sub>4</sub>Ph [190°–195°] and at 100° C<sub>8</sub>H<sub>4</sub>(OH)<sub>2</sub>(CON<sub>2</sub>H<sub>4</sub>Ph)<sub>2</sub> [220°–225°].

**Amide**. [185°].

**SACCHARIN**. The lactone of saccharinic acid (*v. infra*). The name has also been applied to the imide of SULPHOBENZOIDIC ACID.

**SACCHARINIC ACID** C<sub>8</sub>H<sub>12</sub>O<sub>6</sub> i.e.

CH<sub>2</sub>(OH).CH(OH).CH(OH).CMe(OH).CO<sub>2</sub>H.

Formed by boiling an aqueous solution of dextrose, levulose, or invert sugar with lime (Péligot, Bl. [2] 36, 226; C. R. 90, 1141; Scheibler, B. 13, 2212). On setting the acid free it changes, especially on heating, into the anhydride. The salts are v. e. sol. water.—KA': monoclinic tables.—NaA'. [α]<sub>D</sub> = -17.2°.—CaA' (dried at 100°). Formed by boiling the lactone with water and CaCO<sub>3</sub>. Amorphous. [α]<sub>D</sub> = -5.7°.—CuA', 4aq: blue nodules (Kiliani, B. 15, 2955).

**Anhydride** C<sub>8</sub>H<sub>10</sub>O<sub>6</sub>. [161°]. [α]<sub>D</sub> = 9.4°. S. 13 at 15°. **Electrical conductivity**: Walden, B. 24, 2028. H.C. 656,900. H.F. 252,100 (Stohmann, J. pr. [2] 45, 313).

**Preparation**.—A cold solution of 1 kg. of invert sugar in 9 litres of water is treated with 100 g. of powdered lime and allowed to stand, agitating at intervals. After 14 days 400 g. more CaO.H<sub>2</sub> is added, and the mixture again allowed to stand for one or two months, until it no longer reduces Fehling's solution. It is then saturated with CO<sub>2</sub>, the remaining Ca precipitated with oxalic acid, and the filtrate evaporated nearly to a syrup. The saccharin which separates is recrystallised from hot water; the yield is 100 g. (Kiliani, B. 15, 2954).

**Properties**.—Prisms, with bitter taste, v. sol. hot water. Dextrorotatory. Converted by alkalis into levorotatory salts of saccharinic acid. May be volatilised almost without decomposition. Can be extracted by ether, even from solutions containing Na<sub>2</sub>CO<sub>3</sub>. Does not ferment with yeast. Does not reduce Fehling's solution, even after long boiling with dilute H<sub>2</sub>SO<sub>4</sub>. Not attacked by dilute HNO<sub>3</sub>. Conc. HNO<sub>3</sub> forms oxalic acid and saccharonic acid C<sub>8</sub>H<sub>10</sub>O<sub>7</sub>. 1 g. reduces 4.6 g. of KMnO<sub>4</sub>. Oxidised by moist Ag<sub>2</sub>O to formic, acetic, and glycolic acids. Boiling HIAq reduces it to the lactone of γ-oxy-isohexoic acid CH<sub>2</sub>.CH(OH).CH<sub>2</sub>.CHMe.CO<sub>2</sub>H, which is further reduced by HI at 200° to CHMePr.CO<sub>2</sub>H (Liebemann a. Scheibler, B. 16, 1821; Kiliani, A. 218, 371). I and KOH give iodoform. Potash-fusion forms formic and lactic acids (Hermann a. Tollens, B. 18, 1333). Boiling HClAq has no action. Phenyl-hydrazine forms C<sub>8</sub>H<sub>4</sub>O<sub>2</sub>(N<sub>2</sub>H<sub>4</sub>Ph) [165°], crystallising from alcohol in needles, v. sol. water (Fischer a. Passmore, B. 22, 2733). Phenyl cyanate at 165° forms C<sub>8</sub>H<sub>12</sub>N<sub>2</sub>O<sub>6</sub>, crystallising in silky needles

(B. a. V.).—3. By oxidising a mixture of  $\text{NH}(\text{C}_6\text{H}_4\text{NH}_2)_2$  (1 mol.) and aniline (1 mol.) with  $\text{K}_2\text{Cr}_2\text{O}_7$  (B.).

**Properties.**—Golden plates. When freshly precipitated by baryta from the sulphate it is  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{O}_2\text{H}$ , but after frequent recrystallisation from hot water it approximates to  $\text{C}_{18}\text{H}_{12}\text{N}_4$  (Nietzki a. Otto, B. 21, 1590). V. sol. hot water, sol. alcohol, almost insol. ether. Conc.  $\text{H}_2\text{SO}_4$  gives a green colour, changing to blue and red on dilution. Conc.  $\text{HClAq}$  gives a blue colour.  $\text{NaNO}_2$  added to a solution of saffranine hydrochloride forms the diazo-compound  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{Cl}_2$ , which gives a blue solution and yields  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{Cl}_2\text{AuCl}_4$ . This diazo-compound on boiling with alcohol forms  $\text{C}_{18}\text{H}_{12}\text{N}_4$ , the salts of which form red aqueous solutions and dye wool and silk a bluer shade than saffranine. The base  $\text{C}_{18}\text{H}_{12}\text{N}_4$  is also got by adding  $\text{H}_2\text{SO}_4$  till the colour is violet, then adding excess of  $\text{NaNO}_2$  and boiling: it yields  $\text{B'HNO}_3$ ,  $\text{B'H}_2\text{SO}_4$ , and a violet acetyl derivative. Alcoholic potash forms  $\text{NH}_3$  and saffranol. Zinc-dust and  $\text{HCl}$  give leuco-saffranine and, on long boiling,  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{O}$  [130°], crystallising from water in long needles yielding  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{O}$  [173°] and converted by nitrous ether into  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{O}$  [117°], crystallising from alcohol in needles.

**Salts.**—( $\text{C}_{18}\text{H}_{12}\text{N}_4\text{Cl}$ ) $\cdot\text{PtCl}_4$ .— $\text{C}_{18}\text{H}_{12}\text{N}_4\text{Cl}$ . Flat needles with green lustre, al. sol. cold, v. sol. hot water, insol.  $\text{HClAq}$ .— $\text{B'HNO}_3$ . Almost insol.  $\text{HNO}_3$ .

**Di-acetyl derivative**  $\text{C}_{18}\text{H}_{12}\text{Ac}_2\text{N}_4$ .— $\text{B'HCl}$ . Got by heating saffranine hydrochloride with  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  (Nietzki, B. 16, 468). Lustrous brown plates, forming a violet solution in alcoholic soda.— $\text{B'HI}$ .

**Di-methyl-saffranine.** The chloride of this substance  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{Cl}$  is formed, together with  $\text{N}(\text{C}_6\text{H}_4\text{NMe}_2)_2$ , by the action of *p*-nitroso-di-methyl-aniline (1 mol.) on aniline (1 mol.) in alcoholic solution at 100° (Barbier a. Vignon, C. R. 105, 672). An isomeric (?) di-methyl-saffranine got by oxidising a mixture of  $\text{C}_6\text{H}_4(\text{NH}_2)\text{NMe}_2$  and aniline yields  $\text{B'H}_2\text{PtCl}_4$  and  $\text{B'HNO}_3$  (Nietzki, B. 16, 869; 19, 3163). An isomeride is formed by heating benzene-azoxylidine with aniline at 150° (Menton, A. 263, 837). Crystalline, forming a rose-red aqueous solution. A tetramethyl-saffranine  $\text{C}_{22}\text{H}_{22}\text{N}_4$  is got by oxidising di-methyl-phenylene-green mixed with aniline acetate (Bindschedler, B. 16, 867). It yields  $\text{B'HCl}$ , v. e. sol. water and  $\text{B'HNO}_3$ .

**Ethyl-saffranine**  $\text{C}_{18}\text{H}_{12}\text{EtN}_4$ . Formed by boiling *p*-phenylene-ethyl-diamine with aniline,  $\text{K}_2\text{Cr}_2\text{O}_7$ , and dilute  $\text{HOAc}$  (Schweizer, B. 19, 150). Formed also by oxidising phenylene-*p*-diamine, aniline, and ethyl-aniline with  $\text{K}_2\text{Cr}_2\text{O}_7$  and dilute  $\text{HOAc}$  (S.). The hydrochloride forms bluish-green hygroscopic crystals, sol. water and alcohol, insol. ether. Its solutions exhibit olive-green fluorescence.— $\text{B'H}_2\text{PtCl}_4$ : dark lustrous needles.

**Di-ethyl-saffranine**  $\text{C}_{22}\text{H}_{22}\text{N}_4$ . Formed by oxidising a mixture of  $\text{C}_6\text{H}_4(\text{NH}_2)(\text{NEt}_2)$  (1 mol.) and aniline (2 mols.) with  $\text{K}_2\text{Cr}_2\text{O}_7$  (Nietzki, B. 16, 470). Formed also by oxidising a mixture of phenylene-*p*-diamine, aniline, and di-ethyl-aniline with  $\text{K}_2\text{Cr}_2\text{O}_7$  (N.). The alcoholic solution is fluorescent. The hydrochloride is sol.  $\text{HClAq}$ .

$\text{NaNO}_2$  added to its solution in  $\text{HClAq}$  gives a greenish-blue colour due to the diazo-chloride which forms  $\text{C}_{22}\text{H}_{22}\text{N}_4\text{Cl}_2\text{PtCl}_4$ .— $\text{B'H}_2\text{PtCl}_4$ : green needles.

**Acetyl derivative**  $\text{C}_{22}\text{H}_{22}\text{Ac}_2\text{N}_4$ . The hydrochloride is ppd. as glittering brown needles on adding  $\text{NaCl}$  to its aqueous solution.— $\text{B'H}_2\text{PtCl}_4$ .

**Tetra-ethyl-saffranine**  $\text{C}_{26}\text{H}_{26}\text{N}_4$  or  $\text{C}_{26}\text{H}_{26}\text{N}_4\text{OH}$ . Formed by oxidising a mixture of phenylene-di-ethyl-*p*-diamine, aniline, and di-ethyl-aniline with  $\text{K}_2\text{Cr}_2\text{O}_7$  (N.).— $\text{B'H}_2\text{PtCl}_4$ .

**Para-saffranine**  $\text{C}_{22}\text{H}_{18}\text{N}_4$ . Prepared by dissolving mauveine in dilute acetic acid and boiling with  $\text{PbO}_2$ .  $\text{NaOH}$  is added to slight excess, and the red filtrate boiled with some powdered zinc and  $\text{CaCO}_3$  and then  $\text{NaCl}$  added. Commercial saffranine contains some para-saffranine (Perkin, C. J. 35, 728).

**Properties.**—Red-brown pp., dissolving in water or alcohol. It is isomeric or identical with commercial saffranine, prepared from equal molecules of tolylene-*p*-diamine, *o*-toluidine, and aniline. Salts.— $\text{B'HCl}$ .— $\text{B'HNO}_3$ . These salts dye silk a shade more scarlet than saffranine.

**Saffranine**  $\text{C}_{18}\text{H}_{12}\text{N}_4$  or  $\text{C}_{18}\text{H}_{12}\text{N}_4\text{OH}$ . Formed from *o*-toluidine by treatment with nitrous acid and oxidation of the product with  $\text{K}_2\text{Cr}_2\text{O}_7$  (Mène, C. N. 25, 215; Hofmann a. Geyger, B. 5, 526; Dale a. Schorlemmer, C. J. 35, 683). Obtained by heating toluene-azo-*o*-toluidine with *o*-toluidine hydrochloride at 150°–160° (Witt, B. 10, 873), and by adding  $\text{K}_2\text{Cr}_2\text{O}_7$  to a hot solution of tolylene-*p*-diamine hydrochloride (1 mol.) and *o*- or *p*-toluidine hydrochloride (2 mols.) (Witt, B. 12, 939; Bindschedler, B. 13, 207). The commercial saffranine (saffranine hydrochloride) can be purified by recrystallisation from water containing  $\text{HCl}$ , or by treatment with alcohol (Böttger, N. R. P. 23, 181). Reddish-brown crystals, v. sol. water and alcohol, insol. ether. Conc.  $\text{HCl}$  changes the colour of its solution through violet to blue.  $\text{H}_2\text{SO}_4$  turns it blue and finally green. Decolourised by zinc and  $\text{HClAq}$ . Saffranine is also decolourised by glucose and  $\text{NaOHAq}$  on heating, and hence may be used as a test for sugar in urine (Crismar, C. C. 1888, 1510); the colour is restored by atmospheric oxidation. Commercial saffranine (5 g.) is fatal when administered to dogs by subcutaneous injection (Weyl, B. 21, 2191).— $\text{B'HCl}$ . Thin reddish crystals, sol. water and alcohol, insol. ether and  $\text{NaClAq}$ .— $\text{B'H}_2\text{PtCl}_4$ . Yellowish-red crystalline powder, almost insol. water, alcohol, and ether.— $\text{B'HBBr}$ : minute needles.— $\text{B'HNO}_3$ . Slender reddish-brown needles, v. sl. sol. cold water.—Sulphate: needles, m. sol. water.— $\text{B'C}_6\text{H}_5\text{N}_3\text{O}$ : brownish-red insoluble needles.

**Substances of the saffranine class** are formed by heating  $\text{NH}(\text{C}_6\text{H}_4\text{NH}_2)_2$  with (4,3,1)- and (4,2,1)-xylidine and with (5,4,2,1)-cumidine, but not with mesidine, (5,4,3,1)-cumidine, or (5,2,1)-, (6,2,1)-, (5,3,1)-, and (3,2,1)-xylidine (Nietzki, B. 19, 3163).

**Saffranol**  $\text{C}_{18}\text{H}_{12}\text{N}_4(\text{OH})$ . Formed by boiling saffranine hydrochloride with alcoholic potash for 8 days (Nietzki a. Otto, B. 21, 1593). Ppd. as yellowish needles by adding  $\text{HCl}$  to its solution in alkalis. Nearly insol. water, alcohol, and  $\text{HOAc}$ . Conc.  $\text{H}_2\text{SO}_4$  forms a brown solution. Yields a crystalline diacetyl derivative.

**SAFFRON.** The dried stigmas of *Crocus sativus*, used as a colouring matter. It contains crocin (g. v.), croceose (g. v.), picrocrocin (g. v.), polychroite, and an oil  $C_{10}H_{16}O$  (209°) miscible with alcohol and ether but decomposed by water (Quadrat, *J. pr.* 56, 68; Weiss, *J. pr.* 101, 65).

Polychroite  $C_{10}H_{16}O_{18}$ . Dried saffron is washed with ether and extracted with water. The extract is mixed with alcohol and filtered, and the filtrate ppd. by ether. Orange deliquescent mass, v. sol. water, insol. alcohol. Yields glucose on boiling with dilute acids.

**SAFROLE**  $C_{10}H_{10}O_2$ , i.e.

(232°). S.G. 1.0956 (S.); 1.0963 (Gladstone, *C. J.* 59, 290). V.D. 81 (obs. and calc.).  $\mu_D = 1.539$  at  $11^\circ$  (G.).  $n_D = 1.4557$  (Brühl, *B.* 21, 477). H.C.v. 1,243,800. H.C.p. 1,244,700. H.F. 40,300 (Stohmann & Langbein, *J. pr.* [2] 46, 533). The chief constituent of the essential oil of saffrafras (*Sassafras officinalis*) (Grimaux & Ruotte, *A.* 152, 83; J. Schiff, *B.* 17, 1935; Poleck, *B.* 17, 1940; 19, 1094; 22, 2861). Occurs also in the oil obtained from the leaves and fruit of *Illicium religiosum* (Eykmann, *R. T. C.* 4, 36, 45; B. 22, 2757; 23, 864), and in the oil of the camphor tree, *Cinnamomum camphora* (Flückiger, *Ph.* [3] 17, 989). Monoclinic crystals, sol. alcohol and ether. Smells like oil of saffrafras. Inactive to light. Oxidised by dilute  $KMnO_4$  to  $CO_2$ , formic, oxalic, and piperonylic acids, and piperonal. Alcoholic potash converts it into isosafrole. Does not react with hydroxylamine or  $BzCl$ . Does not combine with  $NaHSO_4$ . Bromine forms  $C_{10}H_8Br_2O_2$  [170°] S. (chloroform) 7.

Isosafrole  $C_{10}H_{10}O_2$ , i.e.

(obs.); 81 (calc.). H.C.v. 1,233,600. H.C.p. 1,234,500. H.F. 50,500. Formed by boiling safrole (100 g.) with  $KOH$  (250 g.) in alcohol (500 c.c. of 94 p.c.) for 24 hours (Schiff; Ciamician & Silber, *B.* 23, 1160). Liquid, even at  $-18^\circ$ , miscible with alcohol, ether,  $HOAc$ , and benzene, insol. water and alkalis. Conc.  $H_2SO_4$  forms an intensely red solution. Oxidised by  $K_2Cr_2O_7$  and  $H_2SO_4$  to piperonal and acetic aldehyde. Alkaline  $KMnO_4$  gives piperonylic acid. Bromine in  $CS_2$  forms  $C_{10}H_8Br_2H_2O_2$  [110°], crystallising from ligroin in colourless needles. Sodium reduces it in alcohol solution to  $C_{10}H_{12}O_2$ , or  $C_6H_4Pr \begin{array}{c} \diagup O \\ \diagdown O \end{array} CH_2$  (228°), a liquid miscible with alcohol and ether. Isosafrole is converted by treatment with  $KOH$  and  $MeOH$  into a compound, apparently different from methyl-eugenol, but yielding isovanillic acid on oxidation, and [4:2:1]  $O_2H_2(C_6H_4)(OAc)_2$  on treatment with  $Ac_2O$  (Ciamician & Silber, *B.* 25, 1470).

**Nitrosite**  $C_{10}H_{10}N_2O_4$ , i.e.

25, 1956). Mol. w. 224 (by Raoult's method). [124°].  $Ac_2O$  forms a white modification [124°]. Alcoholic potash forms an isomeride [185°] which yields a mono-acetyl derivative [129°], and a benzoyl derivative [146°].  $KMnO_4$  oxidises

it to piperonylic acid. Reduced by tin and  $HClAg$  to  $C_{10}H_{12}N_2O_4$  or  $CH_2O_2C_6H_4C \begin{array}{c} \diagup O \\ \diagdown O \end{array} N \begin{array}{c} \diagup O \\ \diagdown O \end{array} Me$  [86°].

Mol. w. 197 (by Raoult's method). Zinc and  $HOAc$  yield  $C_{10}H_{10}O_4$ , probably represented by  $(CH_2O_2)C_6H_4CH_2CO.CH_2$  [38°], which yields a phenyl-hydrazide  $C_{10}H_{10}O_4(N_2HPh)$  [97°]. Another product of the action of zinc and  $HOAc$  is  $C_{10}H_{12}N_2O_4$  [180°]; and a third is  $C_{10}H_{12}N_2O_4$  or  $CH_2O_2C_6H_4C \begin{array}{c} \diagup O \\ \diagdown O \end{array} N \begin{array}{c} \diagup O \\ \diagdown O \end{array} Me$  [159°], which

yields a di-acetyl derivative [138°].

**SAGAPENUM.** A gum resin imported from Egypt and Persia, consisting of yellow agglomerated granules, smelling like garlic and having an acrid bitter taste. Softens in the hand. Yields umbelliferone on distillation.  $HNO_3$  forms styphnic acid. Potash-fusion forms resorcin (Brandes, *N. Tr.* 2, 2, 97; Pelletier, *Bull. Pharm.* 3, 481; Johnston, *Tr.* 1840, 361). After moistening with alcohol it dissolves in  $H_2SO_4$ , forming a brown liquid. Sagapenum is only partially soluble in alcohol and ether, but the ethereal extract is not clouded by addition of alcohol.  $FeCl_3$  colours its solutions black (Hirschsohn, *J.* 1875, 859; *Ar. Ph.* [3] 10, 481; 11, 54, 152, 247, 312, 434; *C. C.* 1877, 182).

**SAGE OIL.** Obtained in the south of Europe by distilling sage (*Salvia officinalis*) with water, the plant being cut down in the autumn (M. M. P. Muir, *C. J.* 33, 292; 37, 678; cf. Rochleder, *A.* 41, 4; Herberger, *R. P.* 34, 138; Hlasiwetz, *J. pr.* 51, 355). Contains a terpene (156°), salviol (g. v.),  $C_{10}H_{16}O$  (c. 200°), a camphor  $C_{10}H_{16}O$ , probably a little cymene, and, especially when prepared from English plants, cedrene,  $C_{15}H_{24}$  (c. 260°). The amount of salviol and of camphor is very small at first and increases with the age of the oil, being formed by oxidation of the terpenes. Pure salviol, pure sage terpene, and pure cedrene do not resinify when singly exposed to heat and light; but a mixture of these rapidly darkens.

**SAGO.** Balls of starch got from the pith of certain species of *Sagus* and *Cycas* by stirring with water, allowing to settle, and rubbing the deposit through sieves.

**SALAMANDRINE**  $C_3H_6N_2O_4$ . An alkaloid obtained from the poisonous secretion of the cutaneous glands of the salamander (*Salamandra maculata*). Crystalline, v. sol. water and alcohol (Zalesky, *Bl.* [2] 6, 344). Alkaline in reaction. Poisonous.— $B'H.Cl.$ : needles.

**SALICIN**  $C_{13}H_{16}O_7$ , i.e.

$C_6H_5O_2C_6H_4CH_2CH_2OH$ . Mol. w. 286. [201°] (Schiff, *B.* 14, 304). S. 3-3 at  $11^\circ$  (Piria, *A.* 96, 378).  $[\alpha]_D = -62.6^\circ$  (Tiemann, *B.* 18, 1600; cf. Mosse, *A.* 176, 116; Sorokin, *J. pr.* [2] 37, 331). Occurs in the bark of several species of willow and poplar, e.g. *Salix helix*, *S. amygdalina*, *Populus tremula*, *P. graca* (Leroux, *A. Ch.* [2] 43, 440; Bruconnot, *A. Ch.* [2] 44, 296; Pelouze & Gay-Lussac, *A. Ch.* [2] 44, 220; 48, 111; Piria, *A. Ch.* [2] 65, 281; [3] 1, 257; Bouchardat, *C. R.* 18, 299; 19, 602, 1179; 20, 610, 1635; Gerhardt, *A. Ch.* [3] 7, 215; Tischhauser, *A. 7*, 280). Occurs also in castoreum (Wöhler, *A.* 67, 360).

**Formation.**—1. By digesting an aqueous solution of helicin with sodium-amalgam (Lisenko, *Z.* 1864, 577) or with zinc and  $H_2SO_4$  (Mischal,

*Am.* 5, 172).—2. By boiling populin with lime-water (Piria).

**Preparation.**—Willow bark (8 lbs.) is boiled with water; the filtrate evaporated (to 18 lbs.); mixed while hot with PbO (2 lbs.); digested for 24 hours and filtered; the filtrate evaporated to a syrup and left to crystallise (Duflos, *A.* 8, 200; cf. Peschier, *A. Ch.* [2] 44, 418; Erdmann, *B. J.* 83, 1, 186).

**Properties.**—Trimetric tables;  $a:b:c = .927:1:2.494$ . Sol. water and alcohol, insol. ether. Lævrotatory. Tastes bitter. Neutral to litmus. Its solutions are not pptd. by lead acetate or subacetate, by gelatin, or by tannin. Conc.  $H_2SO_4$  gives a red colour. ICIAq forms a crystalline body (Stenhouse, *C. J.* 17, 827). After injection of salicin, salicylic aldehyde and salicylic acid are found in the urine (Laveran a. Millon, *A. Ch.* [3] 13, 145; Ranke, *J. pr.* 66, 1).

**Reactions.**—1. Decomposed at  $240^\circ$  into saliretin and glucosan.—2. Split up by emulsin and saliva at  $40^\circ$  into glucose and saligenin (Piria; Städeler, *J. pr.* 72, 350).—3. Boiling dilute  $H_2SO_4$  forms glucose and saliretin.—4. Oxidised by chromic acid mixture to  $CO_2$ , formic acid, and salicylic aldehyde.—5. Cold dilute  $HNO_3$  forms helicin. Hot conc.  $HNO_3$  forms picric acid.—6. Potash-fusion forms salicylic acid.—7. Boiling  $NaOH$ aq forms saliretin.—8. HCl and  $KClO_4$  give tetra-chloroquinone.

**Metallic derivatives.**— $C_{11}H_9NaO_7$ . Formed from salicin and NaOEt in alcohol (Perkin, *C. N.* 18, 110). Crystalline.— $Pb.C_{11}H_9O_7$ . Got by adding  $NH_4$ Aq to a hot conc. solution of salicin, and then adding lead subacetate. Bulky white pp.

**Acetyl derivative**  $C_{13}H_{11}AcO_7$ . Needles (from alcohol), nearly insol. water (Schiff, *Z.* [2] 5, 51).

**Benzoyl derivative**  $C_{20}H_{21}O_7$ , i.e.  $C_{11}H_9BzO_7$ . Populin.  $[180^\circ]$ . S.  $0.5$  at  $9^\circ$  (Piria);  $0.4$  at  $15^\circ$ ;  $0.24$  at  $100^\circ$  (Schiff); S. (alcohol)  $1$  at  $16^\circ$ . Occurs in the bark and leaves of the aspen (*Populus tremula*) (Braconnot, *A. Ch.* [2] 44, 296; Piria, *A. Ch.* [3] 34, 278; 44, 866; *A.* 81, 245). Formed by heating salicin with  $Bz_2O$  (Schiff, *A.* 154, 5). Prepared by boiling the leaves of the aspen with water, ppg. with lead subacetate, removing lead from the filtrate by  $H_2S$  and evaporating to crystallisation. Light silky needles (containing 2aq). Tastes sweet. Lævrotatory (Biot a. Pasteur, *C. R.* 34, 607). Sl. sol. water and alcohol, nearly insol. ether.  $K_2Cr_2O_7$  and  $H_2SO_4$  form salicylic aldehyde.  $HNO_3$  (S.G. 1.3) forms benzoyl-helicin. Conc.  $H_2SO_4$  forms a deep-red solution, whence water ppts. a red powder ('rutilin'). Boiling dilute acids split it up into glucose, benzoic acid, and saliretin. Alcoholic  $NH_3$  at  $100^\circ$  forms benzamide, benzoic ether, and salicin. Populin is not hydrolysed by emulsin.

**Di-benzoyl derivative**  $C_{22}H_{21}Bz_2O_7$ . Formed, together with the mono- and tetra-benzoyl derivatives, by heating salicin with  $Bz_2O$  (Schiff). Flocculent mass, nearly insol. water, sl. sol. ether.

**Tetra-benzoyl derivative**  $C_{26}H_{21}Bz_4O_7$ . Amorphous resin, not coloured by cold  $H_2SO_4$ .

**Chloro-salicin**  $C_{11}H_8ClO_7$ . Formed by passing  $Cl$  into water in which salicin is suspended

(Piria, *A. Ch.* [3] 14, 275). Long silky needles (containing 2aq), sol. water and alcohol, insol. ether. Tastes bitter. Resolved by emulsin into glucose and chloro-saligenin. Yields a tetra-acetyl derivative, crystallising from alcohol in prisms.

**Di-chloro-salicin**  $C_{11}H_6Cl_2O_7$ . Formed by the action of  $Cl$  on chloro-salicin. Silky needles (containing aq), nearly insol. cold water, m. sol. alcohol. Gives no colour with  $FeCl_3$  or  $H_2SO_4$ . Split up by emulsin into glucose and di-chloro-saligenin.

**Tri-chloro-salicin**  $C_{11}H_3Cl_3O_7$ . Formed by chlorinating the preceding body in presence of water and  $CaCO_3$ . Yellowish needles (containing aq) (from dilute alcohol), almost insol. cold water.

**Bromo-salicin**  $C_{11}H_7BrO_7$ .  $[160^\circ]$ . Formed by slowly adding Br to salicin (1 pt.) in water (20 pts.) (O. Schmidt, *Z.* [2] 1, 320). Four-sided prisms, v. sol. water and alcohol. Split up by emulsin into glucose and bromosaligenin.

**SALICYL**. The radicle *o*-oxy-benzoyl  $[1:2]C_6H_4(OH).CO$ . The same name is sometimes applied to the radicle *o*-carboxyl-phenyl  $[1:2]CO.H.C_6H_4$  and, rarely, to *o*-oxy-benzyl  $C_6H_4(OH).CH_2$ .

**SALICYLAMIC ACID**. An old name for *o*-AMIDO-BENZOIC ACID.

**SALICYLAMIDE**. The amide of *o*-OXY-BENZOIC ACID.

**SALICYLAMINE**. A name for *o*-OXY-BENZYL AMINE.

**SALICYL-GLYCIDIC ACID** v. *OXY-PHENYL-GLYCIDIC ACID*.

**SALICYL-GLYCOLLIC ACID** is *o*-CARBOXY-PHENOX-ACETIC ACID.

**SALICYLIC ACID** v. *o*-OXY-BENZOIC ACID.

Homosalicylic acid v. *OXY-TOLUIC ACID*.

**SALICYLIC ALDEHYDE** v. *o*-OXY-BENZOIC ALDEHYDE.

**SALICYL-LACTIC ACID** v. *DI-OXY-PHENYL-PROPIONIC ACID*.

**SALICYL-PHENOL** v. *DI-OXY-BENZOPHENONE*.

**SALICYL-RESORCIN** v. *TRI-OXY-BENZOPHENONE*.

**SALICYL-SULPHURIC ACID** v. *CARBOXY-PHENYL SULPHURIC ACID*.

**SALIGENIN** v. *o*-OXY-BENZYL ALCOHOL.

**SALIGENOL**. Another name for *o*-OXY-BENZYL ALCOHOL.

**SALIRETIN** v. *o*-OXY-BENZYL ALCOHOL.

**SALOL** v. *Phenyl ether of o*-OXY-BENZOIC ACID.

**SALT-FORMING OXIDES**. Oxides which form salts, either by reacting with acids (or acidic oxides)—in which case the oxides are basic—or by reacting with basic oxides or hydroxides—in which case the oxides are acidic. For a table showing the compositions and general characters of the characteristic highest salt-forming oxides of each group of elements, v. vol. iii. p. 661. M. M. P. M.

**SALTPETRE**. A common name for potassium nitrate; v. vol. iii. p. 514.

**SALTS**. The earliest use of the word *salt* seems to have been to designate the solid obtained by evaporating sea-water. The term was afterwards applied to solids which more or less resembled sea-salt, especially to those solid bodies which were easily soluble in water. The

study of the compositions of salt-like substances led to the view that they were made up of two parts, one of which was electro-positive with regard to the other. When the compositions of acids had been generalised in the statement that acids are compounds of hydrogen with non-metallic, or negative, elements, the relation of salts to acids was indicated by calling salts metallic derivatives of acids. This conception of the composition of salts included the older view, inasmuch as the metallic derivative of an acid is necessarily a compound of a positive metal with a less positive non-metal, or with a (less positive) group of elements, which non-metal, or group of elements, was combined with hydrogen in the parent acid.

The most general conception of the composition of salts is that which formulates them as  $M_xR_y$ , where M is the positive, or basic, or basylous part, and R is the negative, or acidic, or chlorous part of the salt. Both M and R may be either simple or complex. Common salt, NaCl, is the type of all salts as regards composition; the positive radicle, Na, may be replaced by other metals, or by groups of elements which are positive with regard to the other part of the compound; so the negative radicle Cl may be replaced by other non-metals, or by groups of elements which are negative with regard to the other part of the compound.

When an aqueous solution of a salt is electrolysed, the positive radicle is separated at the negative electrode, and the negative radicle at the positive electrode (secondary reactions may occur). An element may form part of the positive radicle of a salt, and the same element may form part of the negative radicle of another salt. Thus in the electrolysis of a ferric salt the iron travels to the cathode, but in the electrolysis of  $K_4Fe(CN)_6$  the iron travels, with the cyanogen, to the anode. In the electrolysis of  $PtCl_4$ , the Pt is separated at the negative electrode, but in the electrolysis of  $Na_2PtCl_6$ , the Pt is separated, with the Cl, at the positive electrode. We must then regard the radicles of, say,  $FeCl_3$ , as Fe and 3Cl, the radicles of  $PtCl_4$ , as Pt and 4Cl, and the radicles of NaCl as Na and Cl; but we must look on the radicles of  $K_4Fe(CN)_6$  as 4K and  $Fe(CN)_6$ , and the radicles of  $Na_2PtCl_6$ , not as 2Na, Pt, and 6Cl, but as 2Na and  $PtCl_6$ . Again, neither the salt  $K_4Fe(CN)_6$ , nor the salt  $Na_2PtCl_6$ , in aqueous solution, gives the ordinary reactions of iron or platinum; but if these salts were composed of the radicles 4K, Fe, and 6CN, and 2Na, Pt, and 6Cl respectively, we should expect them to show the same qualitative reactions as solutions of  $FeCl_3$  and  $PtCl_4$ . In contrast with these salts is the compound formed by evaporating a mixture of  $K_2SO_4$  and  $CuSO_4$ . The salt thus produced,  $K_2SO_4 \cdot CuSO_4 \cdot 6H_2O$ , when dissolved in water, gives the ordinary reactions of sulphates, of K compounds, and of Cu compounds; moreover, on electrolysis the K and Cu appear at the cathode, and the group  $SO_4$  is set free at the anode (where it reacts with  $H_2O$  to give  $H_2SO_4$  and O).

But all these salts—NaCl,  $PtCl_4$ ,  $FeCl_3$ ,  $K_4Fe(CN)_6$ ,  $Na_2PtCl_6$ , and  $CuSO_4 \cdot K_2SO_4$ —are represented, as regards composition, by the general formula  $M_xR_y$ . This formula satisfactorily ex-

presses the composition of all salts; but it says nothing about the properties of these compounds. When solutions of two salts are mixed, a more or less complete interchange of positive radicles generally takes place. This capability of reacting as if they were composed of two parts—or, one may say, of reacting in a binary way—is characteristic of salts. Salts in solution are most probably dissociated into two parts, each of which carries an electric charge. Even if the whole of the salt is not dissociated, the portion which readily takes part in chemical changes is most probably dissociated binarily (cf. ELECTRICAL METHODS, p. 184).

Salts, then, may be regarded as compounds of the form  $M_xR_y$ , which readily exchange M and R with other compounds of similar composition, and which in aqueous solutions are wholly or partially separated into their positive and negative radicles, each radicle carrying with it an electric charge.

Salts are often classified as *normal*, *acid*, *basic*, and *double salts*.

An acid salt is one whose negative radicle contains hydrogen that can be eliminated by causing the salt to react with an alkali or basic oxide, while a normal salt contains no replaceable hydrogen. As an acid is described as a compound containing hydrogen, all or part of which is replaceable by metal when the acid interacts with a metal or a basic oxide, it is evident that an acid salt comes under the description of an acid, and, strictly speaking, is an acid. According to the meaning already given to the term 'salt,' the class of salts includes acids. It is, however, convenient to give a special name to the compounds of hydrogen with negative radicles. A basic salt contains a positive radicle or radicles which can be replaced by a negative radicle with formation of a normal salt. This positive radicle is sometimes the group OH, sometimes it is a group  $M_xO_y$ , where M is the metal of the salt. Thus  $Bi(OH)_3NO_3$  and  $Pb(PbO)NO_3$  are basic salts. When treated with nitric acid the former gives the normal salt  $Bi(NO_3)_3$ , and the latter the normal salt  $Pb(NO_3)_2$ . The basic salt is an intermediate stage between the base and the normal salt, just as the acid salt is an intermediate stage between the acid and the normal salt.

Basic salts are formed by fairly weak bases; the very strong bases,  $Na_2O$ ,  $K_2O$ ,  $CaO$ , &c., do not form basic salts.

Normal salts frequently combine with other normal salts to form double salts. Generally speaking, one of the components of a double salt is a salt of a strong base which forms acid salts but not basic salts, and the other component is a salt of a weaker base which readily forms basic salts but does not form acid salts. That component which is itself the salt of a strong base—e.g.  $K_2SO_4$ , NaCl, &c.—may be regarded as the more acidic or negative radicle of the double salt, while the component which is itself the salt of a weaker base—e.g.  $Al_2(SO_4)_3$ ,  $Zn_3(PO_4)_2$ , &c.—may be regarded as the more basic or positive radicle of the double salt. The double salt belongs to the type  $M_xR_y$ ; both M and R are themselves salts. And just as many normal salts are formed by the direct union of their radicles—e.g. NaCl by combining Na and

Cl, BaSO<sub>4</sub> by combining BaO and SO<sub>3</sub>—so double salts are formed by the union of a more positive with a less positive radicle, which is, in such cases, itself a salt.

The reactions of some double salts indicate that these salts are to be regarded as composed of the two simple salts which were brought together when the double salts were formed; the salt MgSO<sub>4</sub>.K<sub>2</sub>SO<sub>4</sub>.6aq, for instance, gives, in solution, the reaction of sulphates, of Mg, and of K, and on electrolysis the Mg and K go to the negative electrode. On the other hand, the reactions of some double salts indicate that these salts are not to be regarded as composed of the simple salts by the union of which the double salts were formed; the salt Cr<sub>2</sub>(C<sub>2</sub>O<sub>4</sub>)<sub>3</sub>.K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, for instance, does not give the reactions of oxalates, nor the reactions of Cr: this salt must be looked on as the potassium salt of the acid H<sub>2</sub>Cr<sub>2</sub>(C<sub>2</sub>O<sub>4</sub>)<sub>3</sub>. If the salt (NH<sub>4</sub>)<sub>2</sub>Cr<sub>2</sub>(C<sub>2</sub>O<sub>4</sub>)<sub>3</sub>.2H<sub>2</sub>O is treated with NH<sub>4</sub>Aq, a new salt is formed having the composition Cr<sub>2</sub>(C<sub>2</sub>O<sub>4</sub>)<sub>3</sub>.(NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.4NH<sub>3</sub>.xH<sub>2</sub>O, and the reactions of this salt show that it is an oxalate, and therefore that it has a different constitution from that of the salt (NH<sub>4</sub>)<sub>2</sub>Cr<sub>2</sub>(C<sub>2</sub>O<sub>4</sub>)<sub>3</sub>, from which it is obtained.

The salts of the haloid acids combine to form many double salts, e.g. PbI<sub>2</sub>.KI, BiCl<sub>3</sub>.3KCl, AuCl<sub>3</sub>.KCl, &c. Most of these double haloids are generally regarded as double salts in the usual acceptance of the term; but several of them do not give the ordinary reactions of the less positive metal they contain, nor the reactions of the halogen which enters into their composition. For instance, PtCl<sub>2</sub>.2NaClAq reacts with two equivalents of AgNO<sub>3</sub> to give PtCl<sub>2</sub>.2AgCl; if PtCl<sub>2</sub>.2NaCl were a double salt, reacting in solution as if it were composed of the two radicles PtCl<sub>2</sub> and NaCl, it would interact with six equivalents of AgNO<sub>3</sub>, and the products would be Pt(NO<sub>3</sub>)<sub>2</sub>, NaNO<sub>3</sub>, and AgCl. It is evident, then, that the Na-Pt chloride is the Na salt of the acid H<sub>2</sub>PtCl<sub>4</sub>, and that the constitution of this salt is similar to that of the ordinary simple salts.

Remsen (*Am.* 11, No. 5 [1889]) proposes to regard all the so-called double haloids as simple salts similar to ordinary oxysalts. It seems to me that the constitutions of these salts cannot be determined by an examination of their composition only, but that the reactions of each salt must be examined. Some of the double haloids are undoubtedly simple salts, as some of the double oxysalts are certainly simple salts of metal-containing acids; but as some oxysalts containing two metals react so as to show that they are composed of two radicles, each of which is a simple salt, so some of the double haloids also give the ordinary reactions of both the metals, and also of the acidic radicle, which they contain, and must therefore be regarded as true double salts. M. M. P. M.

**SALVIOL** C<sub>10</sub>H<sub>8</sub>O. (200°). S.G. 1.039.  $\mu_D = 1.462$  at 20°. R<sub>D</sub> 74.2. (M. M. P. Muir, *C. J.* 33, 292; 37, 683). A constituent of oil of Sassa (q. v.). It is a dextrorotatory liquid. On distillation some of it splits up into H<sub>2</sub>O and C<sub>10</sub>H<sub>8</sub>.

**Reactions.**—1. *Chromic acid mixture* or dilute nitric acid produces acetic and oxalic

acids and camphor [174°].—2. P<sub>2</sub>O<sub>5</sub> produces polymerides of C<sub>10</sub>H<sub>8</sub>, a terpene (171°), an aromatic hydrocarbon (c. 130°), and a paraffin-like hydrocarbon (170°–180°). Cymene is not formed. Hence salviol is not C<sub>10</sub>H<sub>8</sub>O. However, according to Semmler (*B.* 25, 3350), salviol is identical with tanacetone.

**Constitution.**—Refractive index appears to indicate absence of C:C groups.

**SALYLIC ACID.** A name given by Kolbe to a supposed isomeride of benzoic acid got from salicylic acid by successive treatment with PCl<sub>5</sub> and sodium-amalgam. It is identical with benzoic acid (Reichenbach & Beilstein, *A.* 132, 309). The name is also applied by Städeler (*A. Suppl.* 7, 159) to two acids: (a) C<sub>7</sub>H<sub>5</sub>O<sub>3</sub> [101°] and (b) C<sub>7</sub>H<sub>3</sub>O<sub>3</sub> [95°], obtained by allowing salicylic aldehyde to stand for 12 years under water. The (a)-acid forms small four-sided prisms, gives no colour with FeCl<sub>3</sub>, and yields Ag<sub>2</sub>A". The (b)-acid forms aggregates of needles, gives an intense violet colour with FeCl<sub>3</sub>, and yields Ag<sub>2</sub>A". Both acids are v. sol. alcohol and ether.

**SAMARIUM.** This name was given by Lecoq de Boisbaudran (*C. R.* 88, 322; 89, 212) to the metal of an earth which he separated from what was then known as didymia, occurring in *samaraskite*. Delafontaine (*C. R.* 89, 632), obtained from didymia an earth which he called *decipia*, and when this had been removed by ppn. as sulphate, the new earth, samaria, remained in solution, and was obtained by fractionally ppg. by NH<sub>4</sub>Aq. Cleve (*C. J.* 43, 362) separated what he regarded as pure samaria from *orthite*; he prepared and described several salts of the new element. Cleve found the at. wt. of Sm to be 150, supposing the oxide to be Sm<sub>2</sub>O<sub>3</sub>; this number was confirmed by Bettendorff (*A.* 263, 164). It is still very doubtful whether samaria is a homogeneous substance; according to Crookes, it contains at least four different bodies (*v. METALS*, *RARE*, vol. iii. p. 244). Because of the great uncertainty attaching to the homogeneous nature of the so-called samaria it does not seem desirable to give an account of the bodies which have been described as compounds of Sm. The student is referred to the memoirs cited above, and also to the following:—L. de Boisbaudran, *C. R.* 114, 575; 116, 611 (spectrum and compounds of samaria); Marignac, *Ar. Sc.* [3] 3, 413 (spectrum, and compounds); Krüss & Nilson, *B.* 20, 2134; 21, 2310 (spectrum); v. also, for spectrum, *B. A.* 1884. 438. The compounds of the supposed element are described by Cleve (*l.c.*, and also *Bl.* [2] 43, 162) (*cf.* also *ELEMENTS*, vol. ii. p. 422). M. M. P. M.

**SANDAL WOOD.** A dye wood furnished by *Pterocarpus santalinus*, which grows in tropical Asia. It dyes mordanted cotton red. It contains santalin (Meier, *A.* 72, 320). Yellow sandal wood (from *Santalum album*), yields by steam-distillation an oil containing santalol C<sub>15</sub>H<sub>26</sub>O, and santal C<sub>11</sub>H<sub>20</sub>O (Chapoteaut, *Bl.* [2] 37, 303). After treatment with Na the oil yields a terpene C<sub>10</sub>H<sub>16</sub>, S.G. 0.919,  $\mu_D = 1.487$  (Gladstone, *C. J.* [2] 10, 6). The crude oil heated in sealed tubes at 310° forms C<sub>10</sub>H<sub>16</sub>O, (c. 840°), C<sub>10</sub>H<sub>16</sub>O<sub>2</sub> (350°) and C<sub>10</sub>H<sub>16</sub>O (240°) whence P<sub>2</sub>O<sub>5</sub> forms C<sub>10</sub>H<sub>14</sub>, (c. 177°).

**Santalol** (310°) is converted by  $P_2O_5$  into water and  $C_{15}H_{22}$  (260°). HOAc at 150° forms the acetyl derivative  $C_{15}H_{22}OAc$  (238°), and a compound  $C_{15}H_{22}O$  (288°).

**Santalal** (300°) is converted by  $P_2O_5$  into  $C_{15}H_{22}$  (248°).

Sandal wood oil from *Santalum Preissianum* contains a crystalline solid [105°] (*Ph.* [3] 22, 328).

**SANDARACH.** A gum resin which exudes from *Thuja articulata* growing in Barbary, and from various species of *Callitris* growing in Australia and New Zealand (Johnston, *J. pr.* 17, 157; Maiden, *Ph.* [3] 20, 562). Transparent yellowish mass with vitreous fracture, resembling pine-resin in taste and smell. Sol. alcohol. Completely sol. ether. Its alcoholic solution is ppd. by  $Pb(OAc)_2$ . It appears to contain several resins (e.g.  $C_{15}H_{22}O_2$ ,  $C_{15}H_{22}O_3$ , and  $C_{15}H_{22}O_4$ ) differing in solubility in alcohol.

**SANGUINARINE**  $C_{17}H_{15}NO_4$  (E. Schmidt, *Ar. Ph.* [3] 26, 622). Prepared from the root of *Sanguinaria canadensis* (Dana, *Annals of the Lyceum of New York*, 2, 245; Probst, *A.* 29, 120; 31, 241; Schiel, *A.* 43, 233; *Am. S.* [2] 10, 220; Naschold, *J. pr.* 106, 385). According to Probst and Schiel it is identical with chelerythrine, but Naschold and Schmidt assign the formula  $C_{17}H_{15}NO_4$  to sanguinarine and  $C_{15}H_{13}NO_4$  to chelerythrine. Prepared by exhausting the root with ether and ppg. the hydrochloride by HCl. Pearly grains, insol. water, sol. alcohol and ether. Poisonous.—**Salts:**  $B'HCl$  aq.— $B'_2H_2PtCl_6$  (dried at 100°).— $B'_2H_2PtCy_4$ . According to König (*C. C.* 1891, i. 321) sanguinarine has the formula  $C_{16}H_{13}NO_4$ , crystallises with 3aq, melts at 211°, and forms the red salts  $B'HCl$  5aq,  $B'IINO_3$  aq,  $B'HAuCl_4$ , and  $B'_2H_2PtCl_6$ .

**SANTAL**  $C_{15}H_{11}O_2$ . Obtained from sandal wood by extracting with very dilute KOH, ppg. with HCl, and extracting the pp. with ether (Weidel, *Z.* [2] 6, 83). It is accompanied by a scarlet crystalline powder  $C_{15}H_{11}O_2$ ? Santal crystallises from alcohol in colourless iridescent four-sided laminae (containing  $1\frac{1}{2}$  aq), insol. water, sl. sol. cold alcohol, sol. KOH aq, sl. sol.  $NH_4$  aq.  $FeCl_3$  colours its alcoholic solution dark red. Potash-fusion yields protocatechuic acid.

**SANTALIN**  $C_{15}H_{11}O_4$  (Meier, *A.* 72, 320);  $C_{15}H_{11}O_5$  (Wegermann a. Häffely, *A.* 74, 226);  $C_{17}H_{13}O_6$  (Franchimont, *B.* 12, 14). [105°]. The colouring matter of sandal wood and of coliatum wood. Extracted by ether or alcohol, and purified by ppg. its alcoholic solution with  $Pb(OAc)_2$ , and decomposing the pp. by dilute  $H_2SO_4$ . Minute red prisms (M.) or amorphous (F.), without taste or smell, insol. water. Its alcoholic solution is blood-red. Sol. alkalis, forming violet solutions in which  $BaCl_2$  ppt.  $Ba(C_2H_3O_2)_2$  as a dark-violet amorphous pp.  $Pb(OAc)_2$  added to its alcoholic solution ppt.  $PbC_2H_3O_2$  (dried at 100°). On heating with HCl, santalin gives off  $MeCl$  (1 mol.). Gives resorcin and HOAc on fusion with potash.  $KMnO_4$  gives off an odour of vanilla.

**SANTONIC ACID**  $C_{15}H_{21}O_4$ , i.e.

$CH_3 \cdot \begin{matrix} CHMe \cdot CH(OH) \\ CHMe \cdot OH \cdot CH(OH) \cdot CH_2 \cdot CO_2H \end{matrix}$  (?) (Cannizzaro, *B.* 18, 2748). [171°] (Hvoslef, *B.* 6, 1471).

S. 56 at 17°.  $[\alpha]_D = -74^\circ$  at 30° in chloroform (Nasini, *B.* 13, 2210; *G.* 13, 164). Formed by boiling santonin with baryta-water (Cannizzaro a. Sestini, *G.* 3, 241; Hesse, *B.* 6, 1280). Colourless trimetric plates (Strüver, *G.* 6, 849), m. sol. hot water, v. sol. ether, v. e. sol. alcohol. Acid to litmus. Levorotatory. HIAq forms  $C_{15}H_{21}O_4$  (235°–245°) and  $C_{15}H_{21}I$  (144° at 3 mm.). (Cannizzaro a. Amato, *B.* 7, 1104). Boiling HIAq and P form (a-) and (β)-metasantonin. By boiling with HOAc and heating the residue it is converted into santonide and parasantonide. Sodium-amalgam yields hydrosantonic acid. Does not react with hydroxylamine. When its chloroform solution is heated with  $POCl_3$  as long as HCl comes off, and a current of damp air passed through the product, there is formed  $PO(C_{15}H_{21}O_4)_2$  [38°] (Cannizzaro, *G.* 10, 459).

**Salts.**— $NaA'$ . Stellate groups of needles.

— $BaA'$ .— $AgA'$ : white pp.

**Methyl ether**  $MeA'$ . (86°). Colourless needles (Cannizzaro, *G.* 6, 335).

**Ethyl ether**  $EtA'$ . [95°].  $[\alpha]_D = -45^\circ$  at 26°. Trimetric crystals.

**n-Propyl ether**  $PrA'$ . (220° at 3 mm.). S.G.  $\frac{2}{3}$  1.125.  $[\alpha]_D = -40^\circ$  at 20°.

**Isobutyl ether**  $CH_3PrA'$ . [67°].  $[\alpha]_D = -41^\circ$ . Needles (Carnelutti a. Nasini, *B.* 13, 2208; *G.* 10, 530).

**Allyl ether**  $C_3H_5A'$ . [55°].  $[\alpha]_D = -40^\circ$ .

**Acetyl derivative**  $C_{15}H_{21}AcO_4$ . [140°]. Got by boiling the acid for six hours with  $AcCl$  (Sestini, *G.* 5, 121). Prisms (from  $CHCl_3$ ). It is accompanied by  $C_{15}H_{21}O_4$  [128°].

**Chloride**  $C_{15}H_{21}O_4Cl$ . [155°].

**Bromide**  $C_{15}H_{21}O_4Br$ . [145°].

**Iodide**  $C_{15}H_{21}O_4I$ . [136°].

**Hydrosantonic acid**  $C_{15}H_{21}O_4$ . [170°].

Formed by reducing santonie acid with sodium-amalgam (Cannizzaro, *G.* 6, 341). Colourless trimetric crystals (from ether), less sol. alcohol than santonie acid. Dextrorotatory. Oxidised by  $Ag_2O$  to metasantonie acid. HOAc at 150° forms hydrosantonide  $C_{15}H_{21}O_5$  [156°], which is reconverted into hydrosantonie acid by alcoholic potash (Cannizzaro a. Valente, *G.* 8, 309).  $AcCl$  converts hydrosantonie acid into acetyl-hydrosantonide  $C_{15}H_{21}AcO_5$  [204°], which is converted by alcoholic  $NH_3$  at 130° into hydrosantonamide  $C_{15}H_{21}O_5NH_2$  [190°].  $BzCl$  forms benzoyl-hydrosantonide  $C_{15}H_{21}BzO_5$  [157°].

**Salts.**— $NaA'$  3aq: trimetric crystals. —  $KA'$  2aq: monoclinic crystals.

**Santonie acid**  $C_{15}H_{21}O_4$ , i.e.

$CH_3 \cdot CH \cdot CH \cdot CHMe \cdot CO_2H$

$CH_3 \cdot CH \cdot CH \cdot CHMe \cdot CH \cdot CH(OH) \cdot CH_2 \cdot CO_2H$  (?)

(Cannizzaro, *B.* 18, 2746). **Santonie acid.**

$\alpha_1 = -26^\circ$  in alcohol at 22°. Formed by heating santonin with KOH aq (Hesse, *B.* 6, 1280). Trimetric tables, sl. sol. cold water, m. sol. ether, v. e. sol. alcohol. Not turned yellow by light. Acid to litmus. Not coloured red by alcoholic potash. At 120° it splits up into water and santonin; dilute  $H_2SO_4$  acts in like manner.

**Salts.**— $NaA'$  3½ aq. S. 33 in cold water. S. (90 p.c. alcohol) 25 (Lepage, *J.* 1876, 618). Stellate groups of needles. Levorotatory;  $\alpha_1 = -18^\circ$  at 22°.— $BaA'$ , aq.

**Metasantonie acid**  $C_{15}H_{21}O_4$ . [161°]. Formed by heating silver hydrosantonate at 150° water. Got also by distilling santonie acid at 45 mm.,

by boiling santonide with KOHAq. and by the action of  $\text{Na}_2\text{CO}_3\text{Aq}$  on isosantonin. Trimetric crystals (from ether). Lævorotatory. Its K and Na salts are very soluble.— $\text{AgA}'$ : pp., m. sol. water.

*Methyl ether*  $\text{MeA}'$ . [103°].

*Chloride*  $\text{C}_{15}\text{H}_{19}\text{O}_4\text{Cl}$ . [139°].

*Parasantonide acid*  $\text{C}_{15}\text{H}_{20}\text{O}_6$ . [173°].  $[\alpha]_D = -99^\circ$  in chloroform (Carnelutti a. Nasini, G. 10, 534). Formed by boiling parasantonide with NaOHAq or HClAq. Trimetric crystals, m. sol. water and ether. Converted by  $\text{AcCl}$ ,  $\text{Ac}_2\text{O}$ , or  $\text{PCl}_5$  into parasantonide. Boiling HIAq and P form (a)- and (β)-metasantonin. The parasantonates are mostly v. sol. water.— $\text{BaA}'_2$ : slender needles (from water).

*Methyl ether*  $\text{Me}_2\text{A}'$ . [184°].  $[\alpha]_D = -109^\circ$  in chloroform at 27°.

*Ethyl ether*  $\text{EtA}'$ . [173°].  $[\alpha]_D = -100^\circ$  in chloroform at 20°.

*n-Propyl ether*  $\text{PrA}'$ . [113°].  $[\alpha]_D = -91^\circ$  at 26°. Colourless prisms.

*Allyl ether*  $\text{C}_3\text{H}_5\text{A}'$ . [149°].  $[\alpha]_D = -92^\circ$ . Lævorotatory.

*Photosantonide acid*  $\text{C}_{15}\text{H}_{22}\text{O}_4$ , i.e.

$\text{CH:CH:CH:CHMe.CO.H}$   
 $\text{CH:CH:CH:CHMe.CH}_2\text{CH(OH).CH}_2\text{CO}_2\text{H}$  (?)

[155°].  $[\alpha]_D = -125^\circ$ . Formed, as ethyl ether of the lactic acid, by exposing a solution of santonin in 65 p.c. alcohol to direct sunlight (Sestini, *Rep. ital. chim. pharm.* 1865). Formed also by exposing an aqueous solution of sodium santonate to sunshine. Prepared by insolation of a 1 p.c. solution of santonin in diluted HOAc for one month (Cannizzaro a. Villavecchia, B. 18, 2750, 2859). Trimetric prisms (from alcohol). Gives off  $\text{H}_2\text{O}$  at 100°, forming the lactic acid  $\text{C}_{15}\text{H}_{20}\text{O}_4$ , and then melts at 155°. V. sl. sol. water, v. sol. alcohol and ether. Lævorotatory.

*Salts*.— $(\text{NH}_4)_2\text{A}''$ . Gaq. —  $\text{BaA}''$  aq: white amorphous pp.— $\text{CaH}_2\text{A}''$ . 3aq: silky needles, sl. sol. cold water.— $\text{CaA}''$  2aq.— $\text{AgA}''$ : white pp.

*Methyl ether of the lactic acid*. [57°]. Got by the action of sunshine on a solution of santonin in MeOH. Long prisms (from MeOH).

*Ethyl ether of the (α)-lactic acid*  $\text{C}_{15}\text{H}_{21}\text{O}_6$ . [69°]. (305°).  $[\alpha]_D = -118^\circ$  in a 6 p.c. alcoholic solution at 14°. Got by exposing an alcoholic solution of santonin to sunlight (Sestini, J. 1876, 622). Formed also from  $\text{AgC}_{15}\text{H}_{20}\text{O}_4$  and  $\text{EtI}$  (V.). Formed also by the action of alcohol and  $\text{H}_2\text{SO}_4$  on photosantonide acid. Thin tables, almost insol. cold water, v. sol. alcohol and ether. Lævorotatory. NaOH converts it into sodium photosantonate.

*Ethyl ether of the (β)-lactic acid*  $\text{C}_{15}\text{H}_{21}\text{O}_6$ . [155°].  $[\alpha]_D = 7^\circ$  in alcohol at 14°. Formed, together with the preceding, by insolation of a solution of santonin in absolute alcohol. Tables (from ether). Dextrorotatory.

*Anhydriphotosantonide acid*  $\text{C}_{15}\text{H}_{20}\text{O}_4$ , i.e.  $\text{C}_{15}\text{H}_{18}(\text{CO}_2\text{H})_2$ . [133°].  $[\alpha]_D = +31.9$ . Obtained by saponification of its ether, which is formed by passing gaseous HCl into a solution of photosantonide acid in absolute alcohol (Villavecchia, B. 18, 2862). Crystalline solid. V. sol. alcohol and ether.— $\text{BaA}''$ : white amorphous solid, v. e. sol. water.

*Di-ethyl ether*  $\text{Et}_2\text{A}''$ : (180°–185°).

$[\alpha]_D = +20.4^\circ$ . Colourless liquid.

*Isophotosantonide acid*  $\text{C}_{15}\text{H}_{20}\text{O}_5$ , i.e.

$\text{CH:CH:CH:CHMe.C(OH).}$   
 $\text{CH:CH:CH:CHMe.CH.CH(OH).CH}_2\text{CO}_2\text{H}$  (?)

$[\alpha]_D = 124^\circ$  in a 3 p.c. alcoholic solution at 11°. Formed, together with photosantonide acid, by exposing a solution of santonin (1 kilo.) dissolved in HOAc (52 litres of S.G. 1.054) for several months to sunshine (Cannizzaro a. Fabris, B. 19, 2260). Thick trimetric crystals (from alcohol), sl. sol. water, m. sol. ether, v. sol. alcohol. Dextrorotatory. At 100° it gives an anhydride  $\text{C}_{15}\text{H}_{20}\text{O}_4$ . Sol. alkalis and hot  $\text{Na}_2\text{CO}_3\text{Aq}$ , forming orange-red solutions.— $\text{BaA}'_2$  aq: white amorphous powder, v. e. sol. alcohol and water.

*Acetyl derivative*  $\text{C}_{15}\text{H}_{21}\text{AcO}_3$ . [183°].  $[\alpha]_D = 59^\circ$ . Transparent needles. Dextrorotatory.

*Di-acetyl derivative*  $\text{C}_{15}\text{H}_{20}\text{Ac}_2\text{O}_3$ . [c. 166°]. Crystals, v. sl. sol. alcohol and ether. Converted into  $\text{C}_{15}\text{H}_{21}\text{AcO}_3$  by heating with absolute alcohol at 120°.

*Pyrophotosantonide acid*  $\text{C}_{15}\text{H}_{20}\text{O}_6$ . [94.5°]. Formed by heating photosantonide acid in a current of  $\text{CO}_2$  or  $\text{H}_2$  (Sestini a. Danesi, G. 12, 83). Got also by heating photosantonide acid with HI (Cannizzaro a. Fabris, B. 19, 2260). Crystals, sol. alcohol and ether.— $\text{BaA}'_2$ . Forms, on distillation,  $\text{C}_{15}\text{H}_{20}$  (222°).

**SANTONIDE**  $\text{C}_{15}\text{H}_{19}\text{O}_4$ . [127.5°].  $[\alpha]_D = 754^\circ$  in chloroform at 20°; 666° in alcohol at 20°. S.V.S. 206. Formed by evaporating a solution of santonide acid in HOAc and heating the residue at 180° (Cannizzaro a. Valente; Carnelutti a. Nasini, G. 10, 528; 13, 149). Trimetric crystals. Dextrorotatory. M. sol. chloroform, v. sl. sol. alcohol. Not attacked by  $\text{PCl}_5$ . Boiling KOHAq forms metasantonide acid.

*Parasantonide*  $\text{C}_{15}\text{H}_{20}\text{O}_6$ . [110°]. S.G.  $\frac{2}{3}$  1.202.  $[\alpha]_D = 897^\circ$  at 26°. S.V.S. 206. Formed by boiling santonide acid with HOAc, evaporating, and heating the residue at 260° (Cannizzaro, G. 8, 309; 10, 528). Trimetric crystals, v. sl. sol. alcohol, m. sol.  $\text{Ac}_2\text{O}$ . Not attacked by  $\text{Ac}_2\text{O}$  or  $\text{PCl}_5$ . Boiling KOHAq converts it into parasantonide acid.

*Metasantonide*. [138°].  $[\alpha]_D = -223^\circ$  at 26°. S.V.S. 236. Prepared by heating santonin with conc.  $\text{H}_2\text{SO}_4$  for some hours at 100° and ppg. by water (Cannizzaro a. Valente, *Rend. Accad. Lincei*, ii.; G. 10, 42). Crystals (from ether). Converted by  $\text{Na}_2\text{CO}_3\text{Aq}$  into metasantonide acid.

**SANTONIN**  $\text{C}_{15}\text{H}_{19}\text{O}_4$ , i.e.

$\text{CH:CH:CH:CHMe.CO}$   
 $\text{CH:CH:CH:CHMe.CH.CH} < \begin{smallmatrix} \text{CH} \\ \text{O} \end{smallmatrix} > \text{CO}$  or

$\text{CH}_2\text{CMe.C.CH}_2\text{CH.O} < \begin{smallmatrix} \text{CH} \\ \text{O} \end{smallmatrix} > \text{CO}$  (Cannizzaro).

$\text{CO.CMe.C.CH}_2\text{CH.CHMe} > \text{CO}$   
Mol. w. 246. [170°]. S.G.  $\frac{22}{1}$  1.247.  $[\alpha]_D = -174^\circ$  in alcohol of 90 v. p. c. (Hesse, A. 176, 125);  $-172^\circ$  in chloroform at 20°. S.  $\cdot 02$  at 17.5°;  $\cdot 4$  at 100°. S. (alcohol) 2.3 at 22.5°; 8 at 50°; 37 at 80°. S. (ether) 2.4 at 40°. S. (chloroform) 23 (Schlimpert, N. Br. Arch. 100, 151). Occurs in wormseed (semen contra, semen cinæ, or semen santonici), the undeveloped flower heads of *Artemisia Vahlana* and other species of *Artemisia* (Kahler, Brandes Archiv, 34, 318; 35,

216; Alms, *ibid.* 34, 319; 89, 190; H. Trommsdorff, A. 11, 190; Heldt, A. 68, 10, 40).

**Preparation.**—From *Artemisia maritima* (Linn.) which contains 2 p.c. The seeds (5 pts.) are treated with lime (1 pt.) and water, and extracted with alcohol. The extract is freed from alcohol by evaporation and neutralised with HCl, when santonin crystallises out. In this process a lime-compound  $(C_{15}H_{10}O)_2Ca$ , is first formed, and afterwards decomposed by HCl, which forms santoninic acid,  $C_{15}H_{10}O_4$ , whence santonin is formed by splitting off  $H_2O$  (Busch, *J. pr.* [2] 85, 822).

**Properties.**—Flattened hexagonal prisms, which turn yellow in light. May be sublimed. Levorotatory, the specific rotation being but little affected by temperature or concentration of the solution (Hesse; Nasini, *G.* 13, 139). Nearly insol. cold water, v. sol. hot alcohol and ether. Poisonous, exerting an anthelmintic action, and producing temporary colour-blindness (Lavater, *Pharm. Viertelj.* 2, 110; Wells, *J. Ph.* [3] 16, 111; Martini, *C. R.* 47, 259; 50, 545). Reacts with hydroxylamine, forming an oxim (Cannizzaro, *B.* 18, 2746); santonin is best administered as oxim (Coppola, *C. C.* 1887, 1206, 1301). Not attacked by aqueous  $KMnO_4$ . Resinified by boiling conc.  $HClAq$ .  $KOH$  turns santonin crimson (especially in presence of alcohol) and forms  $C_{15}H_{10}KO_4$ .  $AcCl$  has no action. Conc.  $H_2SO_4$  containing  $FeCl_3$  gives a violet colour (Lindo, *C. N.* 36, 222; Knapp, *D. P. J.* 268, 42).

**Reactions.**—1. By treatment with 1 mol. of  $PCl_5$  it gives a compound  $C_{15}H_9ClO_2$  [125° uncor.]. With 2 mols. of  $PCl_5$  it gives a compound  $C_{15}H_8Cl_2O_2$  [182° uncor.] (Pawlewski, *B.* 18, 2900). According to Klein (*B.* 26, 982) the compound is  $C_{15}H_9Cl_2O_2$ .—2. Reduced by  $HI$  and  $P$  to santonous acid  $C_{15}H_{10}O_3$ .—3.  $HNO_3$  (S.G. 1.123) at 95° forms  $CO_2$ , succinic, oxalic, and acetic acids, and  $Hcy$  (Wagner, *B.* 20, 1662).—4. Boiling baryta-water forms santoninic acid.—5. Hot  $KOHAq$  forms santoninidic acid.—6. Potash-fusion forms formic and propionic acids (Banfi a. Chiozza, *A.* 91, 112).—7. An alcoholic solution exposed for some months to sunlight forms the ethyl ether of the lactic acid of photosantoninic acid (*v. supra*).—8. A solution in  $HOAc$  exposed to sunshine yields photo- and isophoto- santoninic acids.—9. Forms santonol on distillation with zinc-dust. Distillation over red-hot zinc-dust gives di-methyl-naphthalene (Cannizzaro, *G.* 12, 415).—10. Cold conc.  $HClAq$  forms an isomeride  $C_{15}H_9O_3$  [260°], sl. sol. hot alcohol, insol. water (Andreocci, *B.* 26, 1373).  $[\alpha]_D = +112^\circ$ . This body is not acted upon by hydroxylamine or phenyl-hydrazine, but yields an acetyl derivative  $C_{15}H_9AcO_3$  [156°]. Like santonin it is insol.  $Na_2CO_3Aq$ , but sol.  $NaOHAq$ . It is reduced by zinc-dust and  $HOAc$  to  $C_{15}H_{10}O_3$  [175°]  $[\alpha]_D = -53.3^\circ$  an acid isomeric with santonous acid, which when fused with potash yields propionic acid and di-methyl-( $\beta$ )-naphthol.—11. Br in glacial acetic acid forms  $C_{15}H_9BrO_3.HOAc.Br$ . Crystals (from alcohol), decomposing above 60°. On boiling with alcohol and aniline it yields bromo-santonin  $C_{15}H_9BrO_3$  [161°]. On boiling with  $KOHAq$  the acetate bromide yields santonin (Klein, *B.* 25, 3317).

**Oxim**  $C_{15}H_{10}O_4(NOH)aq$ . [209°] (Klein, *B.*

26, 411; cf. Gucci, *G.* 19, 867). Needles (from dilute alcohol).  $Ac_2O$  yields  $C_{15}H_9O_2(NOAc)$  [166°] or [170°] (*K.*); [203°] (*G.*). The oxim prepared by alkaline hydroxylamine gives with  $HCl$  and  $FeCl_3$  a violet-red colour [*syn-oximic acid*].

**Benzyl ether of the oxim** [152°].  $HIAq$  forms benzyl iodide.

**Phenyl-hydrazide**  $C_{15}H_{10}O_2(N_2HPh)$ . [220°]. Pale-yellow needles (from alcohol), not decomposed by cold acids (Cristaldi, *G.* 17, 526; Grassi, *C. C.* 1887, 1163).

**Chlorosantonin**  $C_{15}H_9ClO_2$ . Formed from santonin and chlorine-water (Heldt, A. 63, 34; Sestini, *B.* 5, 202). Crystalline. Turns yellow in light.

**Di-chloro-santonin**  $C_{15}H_8Cl_2O_2$ . Formed by passing  $Cl$  for a long time through water containing santonin in suspension (Sestini). Groups of small plates (from alcohol). Coloured orange-red by alcoholic potash.

**Tri-chloro-santonin**  $C_{15}H_7Cl_3O_2$ . [213°]. Monoclinic prisms, not coloured by sunshine, m. sol. alcohol and ether.

(a)-Metasantonin  $C_{15}H_9O_3$ . [161°]. (239°). S.V.S. 205.  $[\alpha]_D = 124^\circ$  in chloroform at 20°. Formed, together with ( $\beta$ )-metasantonin, by boiling santoninic acid or parasantonide with  $HIAq$  and  $P$  (Cannizzaro, *G.* 4, 446, 452; 8, 318; 10, 461). Trimetric hemihedral plates (from ether). Dextrorotatory. Not affected by light. Yields  $C_{15}H_9BrO_3$  [212°] and  $C_{15}H_9Br_2O_3$  [184°].

( $\beta$ )-Metasantonin  $C_{15}H_9O_3$ . [186°]. S.V.S. 211.  $[\alpha]_D = 124^\circ$ . Formed as above. Monoclinic crystals. Yields  $C_{15}H_9BrO_3$  [114°] and  $C_{15}H_9Br_2O_3$  [186°].

**Photosantonin**. A name for the ethyl ether of the (a)-lactonic acid of photosantoninic acid (*v. supra*).

**SANTONOUS ACID**  $C_{15}H_{10}O_3$ , i.e.  $C_{15}H_9Me_2(OH).C_2H_4.CO_2H$ ? [179°].  $[\alpha]_D = 74^\circ$  in alcohol at 20°. Formed by boiling santonin with  $HIAq$  and  $P$  (Cannizzaro a. Carnelutti, *B.* 12, 1574; *G.* 12, 393; 13, 385). White needles, v. e. sol. alcohol and ether, sl. sol. cold water, sol.  $Na_2CO_3Aq$ . May be distilled *in vacuo*. Distilled over powdered zinc in a current of hydrogen it yields di-methyl-naphthalene, di-methyl-naphthol, propylene, and a little xylene. On heating with  $Ba(OH)_2$  above 360° it yields  $CO_2$ ,  $CH_4$ , and di-methyl-naphthol  $C_{12}H_{10}OH$  [135°], which yields  $C_{12}H_{11}OMe$  [68°]. Converted by heat into the anhydride of isosantonous acid, and, finally, into di-methyl-naphthol dihydride and propionic acid.

**Salts.**— $NaA'$ . Needles, ppd. by adding ether to its alcoholic solution. V. sol. water.— $BaA'$ .— $AgA'$ : white pp., quickly turning black. *Methyl ether*  $MeA'$ . [82°].

**Ethyl ether**  $EtA'$ . [117°].  $[\alpha]_D = 78^\circ$  in chloroform or 67° in  $HOAc$  at 20°. White crystals, sol. alcohol and ether. Dextrorotatory. Converted by  $BzCl$  into  $C_{15}H_9BzEtO_3$  [78°].  $Na$  added to its ethereal solution ppts.  $C_{15}H_9NaEtO_3$ , whence  $EtI$  produces  $C_{15}H_9EtO_3$  [82°], which on saponification yields ethyl-santoninic acid  $C_{15}H_9EtO_3$  [116°],  $[\alpha]_D = +75^\circ$  in alcohol.

**Isosantonous acid**  $C_{15}H_{10}O_3$ . [155°]. Formed by heating santonous acid, dissolving the resulting anhydride in  $NaOHAq$ , and ppg. with

**HClAq.** Got also by heating santonous acid (1 pt.) with  $\text{Ba}(\text{OH})_2$  (8 pts.) in a bath of molten lead (Cannizzaro a. Carnelutti, *B.* 12, 1574; *G.* 12, 400). Small plates, sl. sol. water, sol. alcohol and ether. Inactive to light. May be distilled *in vacuo*.

**Ethyl ether EtA'.** [125°]. Crystalline.  $\text{BzCl}$  at 100° yields  $\text{C}_{11}\text{H}_{11}\text{BzEtO}_2$  [91°]. Na added to its ethereal solutions gives no pp., but on adding alcohol  $\text{C}_{11}\text{H}_{11}\text{NaEtO}_2$  is thrown down as an amorphous powder, readily decomposed by water. The Na derivative is converted by  $\text{EtI}$  into  $\text{C}_{11}\text{H}_{11}\text{EtO}_2$  [54°], whence alcoholic potash produces  $\text{C}_{11}\text{H}_{11}\text{EtO}_2$  [143°], v. sol. alcohol and ether.

**SAPONIFICATION.** The conversion of the natural fats into soap (and glycerin) by boiling with alkalis. In a more general sense it is used to denote the resolution of compound ethers into acids and alcohols. In the widest sense it is used to denote the production of an acid from a neutral substance by hydrolysis.

**SAPONIN**  $\text{C}_{27}\text{H}_{48}\text{O}_{16}$  (Rochleder, *Z.* [2] 3, 632);  $\text{C}_{27}\text{H}_{48}\text{O}_{16}$  (Stütz, *A.* 218, 231);  $\text{C}_{27}\text{H}_{48}\text{O}_{17}$  (Hesse, *A.* 261, 373). *Struthium. Githagin. Polygalin. Polygalic acid. Senegin.* A glucoside occurring in the common soapwort (*Saponaria officinalis*) (Schrade, *N. Journ. d. Chem.* 8, 548), in the Oriental soapwort (*Gypsophila Struthium*) (Bley, *A.* 4, 283; Bussy, *A.* 7, 168), in quillaja bark (O. Henry a. Boutron-Chârland, *J. Ph.* 4, 249), in the corncockle (*Agrostemma Githago*) (Malapert, *J. Ph.* [3] 10, 339; Scharling, *A.* 74, 351; Christophsohn, *Ar. Ph.* [3] 6, 432, 461), in the root of *Polygala Senega* (Boley, *A.* 90, 211; 91, 117), and in many other plants. White amorphous powder, insol. alcohol and ether, v. e. sol. water. The dilute aqueous solution froths like soap when shaken; the lather is prevented by addition of alcohol. Impure saponin produces sneezing. Saponin begins to turn black at 145° (Blyth), but does not melt or sublime when heated. Baryta forms amorphous ( $\text{C}_{27}\text{H}_{48}\text{O}_{16}$ ) $_2\text{Ba}(\text{OH})_2$ . A solution of saponin is ppd. by lead acetate. Decomposed by boiling dilute acids into sapogenin and sugar  $\text{C}_6\text{H}_{12}\text{O}_6$  ( $[\alpha]_D = 52^\circ$  at 25°) (Rochleder a. Schwarz, *Sitz. W.* 11, 339; Overbeck, *N. Br. Arch.* 77, 135; Schiaparelli; cf. Crawford, *Pharm. Viertelj.* 6, 361; Flückiger, *Ph.* [3] 8, 488).

**Acetyl derivatives**  $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{16}$  [161°].— $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{16}$  [99°].— $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{17}$  [137°].— $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{18}$  [84°] (Stütz).— $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{17}$ .— $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{17}$ .— $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{17}$ .— $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_{17}$  (Hesse).

**Butyryl derivative**  $\text{C}_{27}\text{H}_{48}(\text{C}_4\text{H}_7\text{O})_2\text{O}_{16}$  (Stütz);  $\text{C}_{27}\text{H}_{48}(\text{C}_4\text{H}_7\text{O})_2\text{O}_{17}$  (Hesse). [68°-72°]. According to Schiaparelli (*G.* 13, 422; *Ph.* [3] 14, 801), saponin obtained from soapwort has the formula  $\text{C}_{27}\text{H}_{48}\text{O}_{16}$  is levorotatory,  $[\alpha]_D = -8$  at 20°, yields amorphous  $\text{Ba}_2\text{H}_2(\text{C}_{27}\text{H}_{48}\text{O}_{16})_2$ , and is split up by boiling dilute  $\text{H}_2\text{SO}_4$  into glucose and saponetin  $\text{C}_{10}\text{H}_{20}\text{O}_5$ .

**SAPOGENIN**  $\text{C}_{17}\text{H}_{32}\text{O}_7$ . Formed by hydrolysis of saponin. Concentric groups of needles (from alcohol), sol. ether, insol. water. From solution in dilute potash it is ppd. by conc. KOHAq as flocculent potassium-saponin. Potash-fusion gives acetic and butyric acids and a crystalline compound [128°].

**Oxysapogenin**  $\text{C}_{17}\text{H}_{32}\text{O}_8$  is obtained by the action of HClAq on a glucoside present in the alcoholic extract of *Herniaria* (Barth a. Herzig, *M.* 10, 172).

**SAPPANIN**  $\text{C}_{27}\text{H}_{48}\text{O}_6$ . Formed, together with resorcin and a little pyrocatechin, by fusing extract of sapan wood with NaOH (Schreder, *B.* 5, 572). Crystallises from water in plates (containing 2aq), nearly insol. cold water, v. sol. alcohol and ether, insol.  $\text{CHCl}_3$ . Neutral in reaction.  $\text{FeCl}_3$  colours its aqueous solution red. NaOCl gives a grass-green colour. May be distilled.  $\text{Pb}(\text{OAc})_2$  gives a yellowish pp. Reduces hot Fehling's solution and ammoniacal  $\text{AgNO}_3$ .  $\text{HNO}_3$  forms tri-nitro-resorcin (styphnic acid). Yields diphenyl on distillation with red-hot zinc-dust.  $\text{AcCl}$  gives  $\text{C}_{27}\text{H}_{48}\text{Ac}_2\text{O}_6$ , crystallising from alcohol in prisms. Br and HOAc give  $\text{C}_{27}\text{H}_{48}\text{BrO}_6$ , crystallising from dilute alcohol in needles.

**SAPRINE**  $\text{C}_8\text{H}_{15}\text{N}_2$ . [From *campos*, putrid.] An alkaloid in putrefying flesh (Gautier, *Bl.* [2] 48, 13), v. PTOMAINES.

**SARCINE** v. HYPOXANTHINE.

**SARCOLACTIC ACID** v. LACTIC ACID.

**SARCOLEMMMA** v. MUSCLE.

**SARCOSINE** v. METHYL-AMIDO-ACETIC ACID.

**SARCOSINIC ACID**  $\text{C}_6\text{H}_7\text{NO}_3$ . [195°]. Occurs in a variety of shellac known as Sonora gum (Hertz, *J.* 1876, 912). White silky scales, v. sol. water, insol. alcohol and ether. Cannot be sublimed. Converted by nitrous acid into lactic acid. Forms salts with acids and bases. It is a weaker acid than alanine.

**SARCOSINURIC ACID** v. vol. iii. p. 260.

**SARSAPARILLA** v. PARILLIN.

**SASSAFRAS OIL.** Obtained by steam-distillation from the bark and wood of the root of *Laurus sassafras* of North America. Contains saffrole (*q. v.*) and a terpene  $\text{C}_{11}\text{H}_{18}$  (156°). S.G. 2.835.

**SATIVIC ACID** v. TETRA-OXY-STEARIC ACID.

**SATURATION, CAPACITY OF.** When a base is added to an acid, a point is reached whereat the properties of the base are neutralised by those of the acid, and the properties of the acid are neutralised by those of the base. The compound that is produced—a salt—has neither the properties of the acid nor the properties of the base. The capacity of saturation of an acid is measured by the quantity of a base, taken in formula-weights, which must be added to the quantity of the acid expressed by its formula in order to form a normal salt. The capacity of saturation of a base is measured by the number of formula-weights of an acid which must be added to a formula-weight of the base in order to form a normal salt. The study of the capacities of saturation of acids and bases leads to the classification of acids as monobasic, dibasic, tribasic, &c., and of bases as mono-acid, di-acid, tri-acid, &c. (*v. ACIDS*, vol. i. p. 49; and *ACIDS*, BASICITY OF, vol. i. p. 51). The notion of equivalency also arises from the study of the capacities of saturation of acids and bases (*v. vol. ii. p. 446*).

When chlorine combines with potassium, one atom of the metal is saturated by one atom of the halogen; but three atoms of chlorine are required to saturate a single atom of bismuth or antimony. The notion of a definite capacity of saturation has been extended from the acids and

bases to the atoms of the elements. The development of this conception leads to the hypotheses of valency and atom-linking (B. CLASSIFICATION, vol. ii. pp. 213-215; EQUIVALENCY, vol. ii. p. 446; and FORMULÆ, vol. ii. p. 572). M. M. P. M.

**SAVINE OIL.** *Oilum Sabinae*. The essential oil from *Juniperus Sabina* contains a sesquiterpene  $C_{15}H_{24}$ , which has a crystalline hydrochloride  $C_{15}H_{22} \cdot 2HCl$  [118°] (Wallach, A. 238, 82).

**SAVORY.** Essence of savory (from *Satureja montana*) contains 40 p.c. carvacrol (232°) and two terpenes (174° and 183°) (Haller, C. R. 94, 132). The oil from *Satureja hortensis* contains 20 p.c. cymene, 50 p.c. carvacrol, a terpene (179°). S.G. 1.855, and a very small quantity of a phenol which differs from carvacrol in not being extracted by ether from its dilute alkaline solution, and yields a phosphate [69°] (Jahns, B. 15, 816).

**SCAMMONY.** A purgative gum-resin composed of the dried milky juice of *Convolvulus scammonia* and of other species of *Convolvulus*. It is purified by boiling with alcohol, neutralising the alkaline filtrate by dilute  $H_2SO_4$ , filtering, and evaporating (Perret, Bl. [2] 28, 522). It contains jalapin (q. v.).

**SCANDIUM.** Sc. At. w. 44. Mol. w. unknown. The oxide of a new element was isolated in 1879 by Nilson (B. 12, 554) from *euxenite* and *gadolinite*; the same oxide was obtained, about the same time, by Cleve, also from Scandinavian minerals (Bl. [2] 81, 486 [1879]). The name *scandium* was given to the metal of the new earth by Nilson to denote the locality of the minerals from which the oxide had been obtained. In his first memoir Nilson represented scandia as  $ScO_3$ , and determined the at. w. of Sc to be c. 170; in his second memoir (B. 13, 1439) he adopted Cleve's correction, and formulated the oxide as  $Sc_2O_3$ , and gave the at. w. of the metal as 44. The element scandium has not yet been isolated.

**Occurrence.**— $Sc_2O_3$  is found, along with yttria, ytterbia, &c., in very small quantities in a few rare minerals—*gadolinite*, *keilhaute*, *ytrotitanite*, and *euxenite*. From 4 kilos. *gadolinite* Cleve obtained 8 g.  $Sc_2O_3$ , and 1.2 g.  $Sc_2O_3$  from 3 kilos. *ytrotitanite*.

**Preparation.**—The metal has not been isolated (v. SCANDIUM OXIDE, *infra*).

**Detection.**—Sc salts give a very brilliant emission-spectrum, rich in rays. Thalén (B. 12, 555) gives the wave-lengths of the most characteristic lines as 6304, 6079, 6037 in the orange; 5526 in the yellow (very marked); 5081 in the green; 4415, 4400, 4374, 4325, 4326, 4314, and 4249 in the indigo (v. also B. A. 1884. 440).

**Chemical relations.**—Ten years before Nilson discovered Sc, Mendeleeff asserted that an element would be found in the group of which boron is the first member, and that this element would resemble B and Al. To this unknown element Mendeleeff gave the name *ekaboron*, and he stated the properties of the element and its compounds in detail. The properties of the compounds of scandium correspond with great closeness with those of Mendeleeff's *ekaboron* (p. tables in vol. i. p. 352; cf. vol. iii. p. 815). The properties of *ekaboron* were arrived at by

comparing the properties of pairs of elements related to one another, as regards positions in the periodic arrangement, similarly to *ekaboron* and its atom-analogues. The relations expressed by the following scheme were specially studied by Mendeleeff:

Eb:Al = Ca:Mg = Ti:Si = V:P = Cr:S:

Eb:B = Ca:Be = Ti:C = V:N = Cr:O = Mn:F.

These statements mean, the relations between the properties of Eb and Al are similar to the relations between the properties of Ca and Mg, &c. For a brief working out of similar relations in the case of *eka-aluminium* v. **GALLIUM** (vol. ii. pp. 598-9). Scandium is the second even-series member of Group III. It follows B, and is followed by Y, La, and Yb in the even series of this group. So resembles Al in many respects, but the difference between these elements is shown, among other ways, in the fact that the double sulphate of Sc and K— $Sc_2(SO_4)_3 \cdot 8K_2SO_4$ —is not an alum (v. EARTHS, METALS OF THE; vol. ii. p. 424).

Scandium, chloride of,  $ScCl_3(?)$ . White hygroscopic needles separate on evaporating a solution of the oxide in  $HClAq$  to a syrup;  $HCl$  is given off on heating, and an oxychloride remains as a white powder (Cleve, *loc. cit.*).

Scandium, oxide of,  $Sc_2O_3$ . (*Scandia*). Prepared by ppg. solutions of Sc salts by  $NH_4Aq$ , washing the white, gelatinous, very bulky pp. of hydrated oxide, drying at 100°, and then heating strongly; also obtained by heating to redness Sc nitrate, sulphate, or oxalate. A white, light powder, resembling  $MgO$ ; sol. in hot conc.  $H_2SO_4Aq$  or  $HNO_3Aq$ . S.G. 3.864 (Nilson a. Pettersson, Z. B. 13, 1461). S.H. from 0° to 100° = 153 (N. a. P.).

Scandia is best obtained from *euxenite*. The finely-powdered mineral is fused with  $KHSO_4$ , the product is dissolved in cold water, and ppd. by  $NH_4Aq$ , the pp. is dissolved in  $HNO_3Aq$ , the solution is boiled for some time, filtered from any pp. which forms, and ppd. by oxalic acid; the ppd. oxalates are dried, heated strongly, washed with hot water to remove the  $K_2CO_3$ , dissolved in  $HNO_3Aq$ , and the solution is evaporated to dryness and the residue heated till it melts; the fused nitrates are treated with water, when a pp. forms, consisting of oxide of Th with small quantities of oxides of Ce, U, and Fe; the filtered solution is evaporated to dryness, the nitrates are partly decomposed by heating, and then treated with water; the residue, which contains a basic nitrate of Sc, is evaporated with  $HNO_3Aq$ , and the residue is again heated for some time, treated with water, and the insoluble evaporated with  $HNO_3Aq$ , and so on. This process separates didymia, yttria, and terbia, the nitrates of which earths are not so readily decomposed by heat to basic nitrates as Sc nitrate is. By repeating this process 68 times Nilson (B. 13, 1442) obtained a nitrate solution which showed no absorption bands, and contained only salts of Sc and Yb. The solution of Sc and Yb nitrates is evaporated with conc.  $H_2SO_4$ , saturated  $K_2SO_4Aq$  is added, the salt  $Sc_2(SO_4)_3 \cdot 3K_2SO_4$ , which separates (Yb sulphate remains in solution) is dissolved in water, and ppd. by  $NH_4Aq$ ; the ppd.  $Sc_2O_3 \cdot 2H_2O$  is washed and dissolved in  $HNO_3Aq$ , and Sc oxalate is ppd. by oxalic acid; the ppd. oxalate is washed,

**Barium selenate**  $\text{BaSeO}_4$ . A white salt, obtained by decomposing an alkali selenate by  $\text{BaCl}_2\text{Aq}$ , filtering, and washing. Insol. water and  $\text{HNO}_3\text{Aq}$ ; boiled with  $\text{HClAq}$  gives  $\text{BaSeO}_4$ , which dissolves. S.G. 4.67 at  $22^\circ$  (Schafarik, J. 1863, 15; Michel, C. R. 106, 878).

**Beryllium selenate**  $\text{BeSeO}_4$ . 4aq. Rhombic crystals (Topsøe, W. A. B. 66, 5).

**Cadmium selenate**  $\text{CdSeO}_4$ . 2aq. By dissolving  $\text{CdO} \cdot x\text{H}_2\text{O}$  in  $\text{H}_2\text{SeO}_4\text{Aq}$ , and crystallising; lustrous, rhombic plates; S.G. 3.632 (von Hauer, J. pr. 80, 214). Forms *double salts* with  $\text{NH}_4$  and  $\text{K}$  (Topsøe, l.c.; von H., l.c.; von Gerichten, B. 6, 162).

**Calcium selenate**  $\text{CaSeO}_4$ . 2aq. Resembles  $\text{CaSO}_4$ ; obtained by ppg.  $\text{K}_2\text{SeO}_4\text{Aq}$  by  $\text{Ca}(\text{NO}_3)_2\text{Aq}$ , dissolving in cold water, and ppg. by heating (von Hauer, l.c.). Also formed by fusing  $\text{CaCl}_2$  with  $\text{K}_2\text{SeO}_4$  and  $\text{NaCl}$  (Michel, C. R. 106, 878).

**Chromium selenate**. Not isolated. *Double salts*, which are *alums*, are known, of the composition  $\text{Cr}_2(\text{SeO}_4)_3 \cdot \text{M}_2\text{SeO}_4 \cdot 24\text{aq}$  (Wohlwill, A. 114, 162; Fabre, C. R. 105, 114; Pettersson, B. 6, 1466). *Alums* are also known of the composition  $\text{Cr}_2(\text{SeO}_4)_3 \cdot \text{M}_2\text{SO}_4 \cdot 24\text{aq}$  (von G., l.c.).

**Cobalt selenate**  $\text{CoSeO}_4$ . 7aq. Hydrated salts have been obtained with 6aq and 5aq (v. Mitscherlich, P. 11, 327; Topsøe, W. A. B. 66, 5). Forms *double salts* with  $\text{K}_2\text{SeO}_4$ , and  $(\text{NH}_4)_2\text{SeO}_4$  (T., l.c.; von G., l.c.; von H., l.c.).

**Copper selenate**  $\text{CuSeO}_4$ . 5aq. Blue, transparent, lustrous crystals, isomorphous with the sulphate. By dissolving  $\text{CuO} \cdot \text{H}_2\text{O}$  in  $\text{H}_2\text{SeO}_4\text{Aq}$  (Mitscherlich, P. 11, 330). Forms *double salts* with selenates of  $\text{NH}_4$ ,  $\text{K}$  (Topsøe, l.c.; von G., l.c.); also with  $\text{Mg}$  and  $\text{Zn}$  selenates (Wohlwill, l.c.).

**Didymium selenate**  $\text{Di}_2(\text{SeO}_4)_3$  (Cleve, Bl. [2] 43, 362). Also with 5aq (C., l.c.); and with 6aq (Ererichs a. Smith, A. 191, 350). Forms *double salts* with  $\text{NH}_4$  and  $\text{K}$  selenates (C., l.c.).

**Iron selenate**  $\text{FeSeO}_4$ . 7aq (*Ferrous selenate*). By evaporating, in  $\text{H}_2\text{O}$ , a solution of  $\text{Fe}$ , or  $\text{FeCO}_3$ , in  $\text{H}_2\text{SeO}_4\text{Aq}$ ; resembles  $\text{FeSO}_4 \cdot 7\text{aq}$  (Topsøe, l.c.). Obtained by Wohlwill (A. 114, 189) with 5aq. Forms a *double salt* with  $\text{K}_2\text{SeO}_4$  (von G., l.c.).

**Lanthanum selenate**  $\text{La}_2(\text{SeO}_4)_3$ . 12aq (F. a. S., l.c.).

**Lead selenate**  $\text{PbSeO}_4$ . A white powder; by ppg.  $\text{K}_2\text{SeO}_4\text{Aq}$  by  $\text{Pb}(\text{NO}_3)_2\text{Aq}$  (Schafarik, J. 1863, 15).

**Magnesium selenate**  $\text{MgSeO}_4$ . 6aq. White, monoclinic crystals; isomorphous with the sulphate; S.G. 1.928 (Topsøe, l.c.). Forms *double salts* with  $\text{NH}_4$  and  $\text{K}$  selenates (T., l.c.; von G., l.c.).

**Nickel selenate**  $\text{NiSeO}_4$ . aq. By evaporating solution of  $\text{NiCO}_3$  in  $\text{H}_2\text{SeO}_4\text{Aq}$  (Mitscherlich, l.c.; Wohlwill, l.c.). Forms *double salts* with selenates of  $\text{NH}_4$  and  $\text{K}$  (von G., l.c.; von Hauer, J. pr. 80, 214).

**Mercury selenates**. 1. *Mercuric selenate*,  $\text{HgSeO}_4$ . By digesting  $\text{HgO}$  with  $\text{H}_2\text{SeO}_4\text{Aq}$ , or by adding excess of  $\text{H}_2\text{SeO}_4\text{Aq}$  to mercuric acetate, and evaporating; a yellowish-white solid. Decomposed by water, giving a *basic salt*  $\text{HgSeO}_4 \cdot 2\text{HgO}$  (Cameron a. Davy, Trans. I. 28, 187). 2. *Mercurous selenate*,  $\text{Hg}_2\text{SeO}_4$ ; by ppg.

$\text{HgNO}_3\text{Aq}$  by  $\text{K}_2\text{SeO}_4\text{Aq}$  (C. a. D., l.c.). With  $\text{NH}_4\text{Aq}$  forms  $(\text{NH}_4)_2\text{SeO}_4 \cdot 2\text{aq}$ .

**Potassium selenates**. The *normal salt*,  $\text{K}_2\text{SeO}_4$ , is obtained by fusing  $\text{Se}$ ,  $\text{K}_2\text{SeO}_3$ , or native lead selenide, with  $\text{KNO}_3$ , dissolving in hot water, allowing to cool partly, pouring off from excess of  $\text{KNO}_3$ , which separates, and collecting the crystals which separate from the mother-liquor. Equally sol. hot and cold water (Mitscherlich, P. 9, 623; 11, 327). Closely resembles  $\text{K}_2\text{SO}_4$ . The *acid salt*  $\text{KHSeO}_4$  is obtained like, and closely resembles,  $\text{KH}_2\text{SO}_4$  (M., l.c.).  $\text{K}_2\text{SeO}_4$  forms many *double salts*; with  $\text{MSO}_4$ ,  $\text{M} = \text{Cd}, \text{Co}, \text{Cu}, \text{Fe}, \text{Mn}, \text{Hg}$ , and  $\text{Zn}$  (von Gerichten, B. 6, 162); with  $\text{Al}_2(\text{SeO}_4)_3$  and  $\text{Cr}_2(\text{SeO}_4)_3$ , the compounds being *alums* (von G., l.c.; Pettersson, B. 9, 1559, 1676; Schröder, J. pr. [2] 22, 432; Fabre, C. R. 105, 114).

**Silver selenate**  $\text{Ag}_2\text{SeO}_4$ . Similar to, and isomorphous with,  $\text{Ag}_2\text{SO}_4$  (Mitscherlich, l.c.).

**Sodium selenate**  $\text{Na}_2\text{SeO}_4$ . Prepared like  $\text{K}_2\text{SeO}_4$ ; separates with 10aq when crystallised below  $40^\circ$  (M., l.c.).

**Strontium selenate**  $\text{SrSeO}_4$ . Obtained by fusing  $\text{SrCl}_2$  with  $\text{NaCl}$  and an alkali selenate; S.G. 4.23. Exactly resembles *celestine* in crystallographic and optical properties (Michel, C. R. 106, 878).

**Thallium selenate**  $\text{Tl}_2\text{SeO}_4$ . By dissolving  $\text{Tl}_2\text{CO}_3$  in  $\text{H}_2\text{SeO}_4\text{Aq}$ , and evaporating. Forms white, prismatic needles, isomorphous with  $\text{K}_2\text{SeO}_4$ ; sl. sol. cold water; insol. alcohol or ether (Kuhlmann, Bl. 1864 [1] 330; Oettinger, Zeit. Chem. Pharm. 1864, 440). Forms *double salts*, which are *alums*, with  $\text{Al}_2(\text{SeO}_4)_3$  and with  $\text{Cr}_2(\text{SeO}_4)_3$  (Fabre, C. R. 105, 114).

**Zinc selenate**  $\text{ZnSeO}_4$ . 7aq. Various hydrates are known (v. Mitscherlich, P. 11, 326; 12, 144; Topsøe, l.c.). Forms a *double salt* with  $\text{Tl}_2\text{SeO}_4$  (Werther, Bl. 1865 [1] 60); also with  $\text{K}_2\text{SO}_4$  (von Gerichten, B. 6, 162).

**THIOSELENATES**  $\text{M}_2\text{SeSO}_4$ . (*Selenothiosulphates*. *Selenosulphates*.) Solutions of the normal alkali sulphites dissolve  $\text{Se}$ , forming these salts. The acid has not been isolated. The salts correspond with the thiosulphates,  $\text{S}$  being replaced by  $\text{Se}$ .

**Potassium thioselenate**  $\text{K}_2\text{SeSO}_4$ . aq. Formed by mixing  $\text{K}_2\text{SeAq}$  with  $\text{SO}_2\text{Aq}$  (Clöëz, Bl. 3, 112; [2] 4, 419). Better prepared by digesting  $\text{K}_2\text{SO}_4\text{Aq}$  with excess of  $\text{Se}$ , filtering the cold liquid from  $\text{Se}$ , and concentrating without heat; crystals of  $\text{K}_2\text{SO}_4$  mixed with  $\text{K}_2\text{Se}_2\text{O}_8$  (v. *infra*) separate, and  $\text{K}_2\text{SeSO}_4$  crystallises from the mother-liquor (Clöëz, l.c.; Rathke, J. pr. 95, 1). White, lustrous, six-sided tablets; deliquescent in moist air; effloresce over  $\text{H}_2\text{SO}_4$ . Decomposed rather easily by heat, giving  $\text{K}$  polyselenides; cold water separates  $\text{Se}$ , and forms  $\text{K}_2\text{Se}_2\text{O}_8$  (v. *infra*); acids evolve  $\text{SO}_2$ , and separate  $\text{Se}$ ;  $\text{BaCl}_2\text{Aq}$  ppts.  $\text{BaSO}_4$  and  $\text{Se}$  from an aqueous solution of the salt; an ammoniacal solution of  $\text{Ag}_2\text{O}$  forms  $\text{Ag}_2\text{Se}$  and  $\text{K}_2\text{SO}_4\text{Aq}$  on heating.

**DITHIO - TRISELENATES**  $\text{M}_2\text{Se}_2\text{SeO}_4$ . (*Selenotrichionates*.) These salts may be regarded as derived from trithionates ( $\text{M}_2\text{S}_3\text{O}_4$ ) by replacing  $\text{S}$  by  $\text{Se}$ ; as the salts  $\text{M}_2\text{S}_3\text{O}_4$  are called trithionates, so the salts  $\text{M}_2\text{Se}_2\text{SeO}_4$  might be called triselenates if they were isolated, and the salts  $\text{M}_2\text{S}_2\text{SeO}_4$  may be called dithio-triselenates.

**Potassium dithio-triselenate**  $K_2SeS_2O_6$ . This salt is formed in the preparation of potassium thioselenate (*v. supra*); if  $KHSO_3$  is present in the  $K_2SO_4$  used considerable quantities of  $K_2SeS_2O_6$  are produced (Rathke, *J. pr.* 95, 1). It is also obtained by mixing  $K_2SeSO_5$  with excess of  $K_2SO_4$  and conc.  $H_2SeO_3$  Aq. Forms lustrous, greenish-yellow, monoclinic prisms, isomorphous with  $K_2S_2O_8$ ; stable in air; sol. water without change (Rathke, *J. pr.* [2] 1, 33). Acids evolve  $SO_2$  and ppt. Se, on warming; ammoniacal solution of  $Ag_2O$  ppts.  $Ag_2Se$ , forming also  $K_2SO_4$  Aq and  $H_2SO_4$  Aq.

**Dithio-triselenic acid**,  $H_2SeS_2O_6$ , is said to be present in the solution obtained by the action of excess of  $SO_2$  on  $SeO_3$  Aq (Schulze, *J. pr.* [2] 32, 390). M. M. P. M.

**SELENHYDRIC ACID**  $H_2Se$ ; *v.* HYDROGEN SELENIDE, vol. ii. p. 724.

**SELENIC ACID**  $H_2SeO_4$ . Mol. w. not determined. S.G. 2.9508 at  $15^\circ$ ; S.G. of super-fused acid, 2.6083 at  $15^\circ$  (Cameron & Macallan, *Pr.* 46, 13). Melts at  $58^\circ$ ; the molten acid may be cooled below  $5^\circ$  without solidifying (C. a. M., *l.c.*). H.F.  $[SeO_3^2 \text{ Aq}] = 76,660$ ;  $[SeO_4^2 \text{ Aq}] = 20,500$  (*Th.* 2, 279).

**Formation**.—1. By passing Cl into  $H_2SeO_3$  Aq, and evaporating.—2. By fusing Se or  $SeO_2$  with  $KNO_3$ , ppg.  $BaSeO_4$  from solution of the fused mass, decomposing by  $K_2CO_3$ , filtering from  $BaCO_3$ , neutralising any  $K_2CO_3$  present by  $HNO_3$  Aq, ppg.  $PbSeO_4$ , and decomposing this salt by  $H_2S$  (von Gerichten, *A.* 168, 214).—3. By heating Se with  $HNO_3$  Aq, boiling with  $HCl$  Aq to reduce any  $H_2SeO_3$  to  $H_2SeO_2$ , ppg. traces of  $H_2SO_4$  by adding a little  $Ba(NO_3)_2$  Aq, filtering from  $BaSO_4$ , neutralising by  $Na_2CO_3$ , evaporating to dryness, heating to dull redness, boiling with  $HNO_3$  Aq, ppg.  $PbSeO_4$ , by addition of  $Pb(NO_3)_2$  Aq, and decomposing by  $H_2S$  (Fabian, *A. Suppl.* 1, 241).—4. By fusing  $SeO_2$  with excess of  $KNO_3$ , boiling with  $HNO_3$  Aq, ppg.  $CaSeO_4$  by addition of  $Ca(NO_3)_2$  Aq, decomposing the  $CaSeO_4$  by addition of  $CdCl_2$ , and decomposing the  $CdSeO_4$  so obtained by  $H_2S$  (von Hauer, *J. pr.* 80, 214).—5. By adding  $AgNO_3$  or  $Ag_2CO_3$  to a solution of pure  $SeO_2$  in water, digesting the ppt.  $Ag_2SeO_4$  with water and a slight excess of Br, filtering from  $AgBr$ , and evaporating the filtrate, which contains  $H_2SeO_4$  (Thomsen, *B.* 2, 598).—6. By oxidising  $H_2SeO_3$  Aq by  $K_2CrO_4$  Aq,  $PbO_2$ , or  $MnO_2$  (Wohllwill, *A.* 114, 169, 176).

**Preparation**.— $SeO_2$  is heated till sublimation begins; it is then dissolved in water, and  $BaO$  Aq is added so long as a few drops, when filtered, continue to give a pp. with  $BaO$  Aq; the filtered liquid is now free from  $H_2SO_4$  and  $H_2SeO_3$ , it is evaporated to dryness, and the residual  $SeO_2$  is heated till it sublimes (Thomsen, *B.* 2, 598). The pure  $SeO_2$  thus obtained is dissolved in water, excess of  $AgNO_3$  Aq is added, the ppt.  $Ag_2SeO_4$  is washed with water and shaken with water and Br—at first Br is added, and then  $Br$  Aq till the liquid shows a faint orange colour; the liquid filtered from  $AgBr$  contains only  $H_2SeO_4$ , it is evaporated and treated as described hereafter (T., *l.c.*). Another method consists in neutralising the solution of pure  $SeO_2$  by  $K_2CO_3$ , evaporating to dryness, fusing with a

little  $KNO_3$  for some time, dissolving in water, slightly acidifying with  $HNO_3$  Aq, boiling for some time to decompose any nitrate present, allowing to cool, adding  $Pb(NO_3)_2$  Aq, washing the ppt.  $PbSeO_4$ , suspending this salt in water, and decomposing it by a rapid stream of  $H_2S$ ; the filtered liquid is then evaporated (von Gerichten, *A.* 168, 214).

The solution of  $H_2SeO_4$  is concentrated by evaporation in an open dish on a water-bath so long as water passes off; an acid containing c. 83–84 p.c.  $H_2SeO_4$  is thus obtained; this acid is placed in a small flask connected with a short wide tube containing solid KOH, which is connected with a large U tube also containing solid KOH; the U tube is connected with the receiver of an air-pump, or with a vessel in connection with a good water-pump. The air is pumped out of the apparatus, and when a good vacuum is obtained the small flask is heated to  $100^\circ$  so long as acid distils over (this is known by the KOH effervescing slightly, as ordinary KOH contains  $K_2CO_3$ ); the temperature is then raised to  $180^\circ$  (an oil-bath being used to heat the flask), and heating at this temperature is continued so long as acid distils off; as soon as the potash ceases to be acted on the heating is stopped and the flask is at once cooled; a very good vacuum must be maintained throughout the process.  $H_2SeO_4$  crystallises as the flask is cooled. A small quantity of  $H_2SeO_4$  Aq should be evaporated thus at a time (Cameron & Macallan, *Pr.* 46, 13).

**Properties**.—A white crystalline solid, crystallising in long hexagonal prisms, and melting at  $58^\circ$  to a colourless oily liquid. The liquid acid may be cooled below  $5^\circ$  without solidifying if it is not stirred; a crystal of  $H_2SeO_4$  dropped into the liquid causes it to solidify at once, the temperature rising to  $58^\circ$ . The liquid acid is specifically lighter than the solid (*v. data* at beginning of article) (C. a. M., *l.c.*).  $H_2SeO_4$  is very hygroscopic; it mixes with water, with production of heat.

The following table is taken from Cameron and Macallan (*l.c.*):—

P.c. $H_2SeO_4$	S.G. $H_2SeO_4$ Aq at $15^\circ$	P.c. $H_2SeO_4$	S.G. $H_2SeO_4$ Aq at $15^\circ$
99.73	2.6083	90	2.3848
99.5	2.6051	89	2.3568
99.0	2.5975	88	2.3291
98.5	2.5863	87	2.3061
98.0	2.5767	86	2.2795
97.5	2.5695	85	2.2558
97	2.5601	84	2.2258
96	2.5388	83	2.1946
95	2.5163	82	2.1757
94	2.4925	81	2.1479
93	2.4596	80	2.1216
92	2.4322	79	2.0922
91	2.4081	73.5	1.9675

**Reactions**.—1. With water much heat is produced, and hydrates are probably formed (*v. infra*, *Hydrates of selenic acid*).  $H_2SeO_4$  acts as a dehydrating agent, similarly to  $H_2SO_4$  (C. a. M., *l.c.*).—2. Heated *in vacuo* begins to decompose into  $O$ ,  $H_2O$ , and  $SeO_2$  at c.  $200^\circ$ ; the water formed dilutes the remaining acid, which then distils over. When dilute  $H_2SeO_4$  Aq is heated at ordinary pressure water distils off till temperature rises to  $205^\circ$ , when the acid has the

composition  $\text{H}_2\text{SeO}_4 \cdot \text{H}_2\text{O}$ ; traces of  $\text{H}_2\text{SeO}_3$  then distil over; at  $260^\circ$  white fumes of  $\text{H}_2\text{SeO}_3$  come off. When  $\text{H}_2\text{SeO}_4$  is strongly heated at the ordinary pressure, some of it is decomposed to  $\text{SeO}_2$ ,  $\text{O}_2$ , and  $\text{H}_2\text{O}$ ; the remaining acid is diluted by the water till a dilute acid distils off (C. a. M., l.c.).—3. Dilute  $\text{H}_2\text{SeO}_4$  dissolves many metals, with evolution of  $\text{H}$ ; warm conc. acid dissolves copper and gold, with partial reduction to  $\text{H}_2\text{SeO}_3$ .—4. Digestion with hydrochloric acid reduces  $\text{H}_2\text{SeO}_4$  to  $\text{H}_2\text{SeO}_3$ , with evolution of  $\text{Cl}$ ; the acid is not reduced by sulphur dioxide nor by sulphuretted hydrogen.—5. Sulphur reacts with liquid  $\text{H}_2\text{SeO}_4$  at c.  $60^\circ$ , forming a deep-blue, very unstable substance ( $?\text{SeSO}_3$ ) which decomposes to  $\text{SO}_2$  and  $\text{H}_2\text{SeO}_3$  (C. a. M., l.c.).—6. Selenion dissolves in  $\text{H}_2\text{SeO}_4$ , giving a green unstable substance— $?\text{Se}_2\text{O}_3$  (C. a. M., l.c.).—7. Tellurium dissolves in  $\text{H}_2\text{SeO}_4$ , forming a reddish body, probably  $\text{TeSeO}_3$  (C. a. M.).—8. Heated with phosphoric anhydride,  $\text{SeO}_2$  is given off; but at a lower temperature crystals were obtained which C. a. M. think were  $\text{SeO}_3$ .

**HYDRATES OF SELENIC ACID.** The monohydrate  $\text{H}_2\text{SeO}_4 \cdot \text{H}_2\text{O}$  was obtained by C. a. M. (l.c.) by diluting  $\text{H}_2\text{SeO}_4$  to 88.96 p.c., freezing at  $-23^\circ$ , melting and re-crystallising by freezing several times. This hydrate forms long needles, melting at  $25^\circ$ , and remaining liquid even  $50^\circ$  below its melting-point; Pickering (*priv. comm.*) gives melting-point as  $16.6^\circ$ . S.G. of solid hydrate = 2.6273 at  $15^\circ$ ; S.G. of superfused hydrate = 2.3557 at  $15^\circ$ . C. a. M. did not succeed in obtaining other hydrates as solids. For salts of  $\text{H}_2\text{SeO}_4$  v. SELENATES, p. 433.

M. M. P. M.

**SELENIDES.** Se combines with most metals when heated with them. Se also combines with many non-metals, e.g. with B, Br, Cl, F, H, I, O, P, and S. Many metallic selenides are formed by heating the elements together (Uelsmann, A. 116, 122; Schneider, A. 97, 192; Little, A. 112, 211); also by the interaction of Se and metallic salts (Schneider, P. 127, 642; Potilitzin, B. 12, 697); sometimes by the interaction of Se and metallic sulphides at high temperatures (P., l.c.). For thermal data regarding the formation of many metallic selenides v. Fabre (C. R. 102, 1469; 103, 269, 345). Selenides of the alkali metals are sol. water; they are formed by saturating the hydroxides in water by  $\text{H}_2\text{Se}$  (Fabre, C. R. 102, 613), by reducing the selenites by  $\text{C}$  (Wöhler a. Dean, A. 97, 1), by reducing selenates by  $\text{H}$  at  $200^\circ$  (Fabre, C. R. 102, 1469), and by heating the elements together (Uelsmann, A. 116, 122). The selenides of metals other than the alkali metals are insol. water.

M. M. P. M.

**SELENION.** Se. (*Selenium*). At. w. 78.8. Mol. w. 157.6 (v. *infra*). M.P.  $217^\circ$  for crystalline variety (Hittorf, P. 84, 214; Draper a. Moss, C. R. 33, 1; v. *Action of heat on selenium*). Boils at  $676^\circ$ – $683^\circ$  (Carnelley a. Williams, C. J. 35, 563). S.G. c. 4.7 crystalline; c. 4.3 amorphous (for more details v. description of varieties of Se, *infra*). V.D. 111 at  $860^\circ$ , 92 at  $1040^\circ$ , 82 at  $1420^\circ$  (Deville a. Troost, C. R. 49, 239; 56, 891). S.H. crystalline  $-20^\circ$  to  $+7^\circ$  =  $-0.732$ , crystalline  $20^\circ$  to  $98^\circ$  =  $-0.762$ , amorphous  $-27^\circ$  to  $+8^\circ$  =  $-0.746$ , amorphous  $19^\circ$  to  $87^\circ$  =  $-1.036$  (Regnault,

A. Ch. [3] 46, 257). C.E. vitreous at  $40^\circ$  = 0000368 (Fizeau, C. R. 68, 1125; cf. Spring, B. 14, 2580). For E.C. v. *infra*.  $\mu_s = 2.654$ ,  $\mu_a = 2.692$ ,  $\mu_D = 2.98$  (v. Sirks, P. 143, 429). For emission and absorption spectra v. B. A. 1884. 440. H.C.  $[\text{Se}_2\text{O}^+] = 57,080$ ;  $[\text{Se}_2\text{O}^+\text{Aq}] = 56,160$ ;  $[\text{Se}_2\text{O}^+\text{Aq}] = 76,660$  (Th. 2, 274).

**Historical.**—In 1817 Berzelius (S. 23, 809) obtained a new element from the crystals formed in the leaden chamber of a sulphuric acid works at Gripsholm in Sweden; as the new element was found to resemble tellurium (discovered in 1798 by Klapstock), Berzelius gave it the name selenion ( $\sigma\epsilon\lambda\eta\eta$  = the moon). As Se is distinctly a non-metallic element, and as the termination *um* is characteristic of the names of metals, it seems altogether improper to use the name selenium rather than selenion.

**Occurrence.**—In small quantities uncombined with other elements; in combination with various metals, such as Bi, Cu, Pb, Hg, Ag, generally along with sulphur. Most selenion-containing metallic sulphides are very poor in Se; but certain selenides from the Argentine Republic contain from 29 to 48.5 p.c. Se, combined with Cu, Pb, and Ag. Minerals containing Se are fairly widely distributed, but occur only in small quantities (Stromeyer, S. 43, 452; MacIvor, C. N. 56, 251; Nordström, B. 12, 1723; Pisani, C. R. 88, 391; Hensler a. Klinger, B. 18, 2556; Stelzner, J. 1874, 1234). When sulphides which contain Se are roasted, the Se condenses in the flues. The deposits that form in sulphuric acid chambers often contain Se; and many specimens of the acid also contain this element. Commercial  $\text{HClAq}$  sometimes contains Se, derived from the  $\text{H}_2\text{SO}_4$  used in making the  $\text{HClAq}$  (Kempor, J. 1860, 84; Nilson, B. 7, 1719; Lamy, C. R. 74, 1285; Scheurer-Kestner, C. R. 74, 1286; Personne, C. R. 74, 1199; Drinkwater, An. 8, 63).

**Formation.**—1. By passing  $\text{SO}_2$  into  $\text{H}_2\text{SeO}_4$  aq;  $\text{H}_2\text{SeO}_4$  aq +  $2\text{SO}_2$  +  $\text{H}_2\text{O}$  =  $2\text{H}_2\text{SO}_4$  + Se.—2. By allowing the solution of an alkali selenide to stand in air (Böttger, J. pr. 71, 512).—3. By adding acid to solution of a thio-selenate (Böttger, J. pr. 94, 439), or to  $\text{KCNSeAq}$  (Oppenheim, J. pr. 71, 266).—4. By the action of such metals as Zn or Fe on  $\text{H}_2\text{SeO}_4$  aq made strongly acid by  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ .—5. By heating  $(\text{NH}_4)_2\text{SeO}_4$  or  $(\text{NH}_4)_2\text{SeO}_3$ .

**Preparation.**—1. From the flue-dust formed in roasting sulphides containing Se. The flue-dust is washed with water, dried, and distilled; this method is applicable to dusts rich in Se. Dusts poorer in Se are washed, the heavier particles are lixiviated with dilute  $\text{HClAq}$  and then with water, dried, fused with pearl ash and soda, and washed with water; the solution of alkali selenide thus obtained is allowed to stand in the air, and the Se which ppts. is washed, dried, and distilled (Böttger, J. pr. 71, 512). Or the washed dust is made into a thin paste with equal volumes of  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{O}$ , heated to boiling, with addition from time to time of a little  $\text{HNO}_3$  or  $\text{KClO}_4$ , till the red colour of the liquid is destroyed, conc.  $\text{HClAq}$  is added equal to half the volume of the liquid, and the whole is evaporated to one-fourth its bulk, whereby  $\text{Cl}$  is evolved and  $\text{H}_2\text{SeO}_4$  is reduced to  $\text{H}_2\text{SeO}_3$ ;  $\text{SO}_2$  is passed into this solution, the ppt. Se is

washed, dried, and distilled (Wöhler, *G. A.* 69, 264).—2. *From the deposit in the leaden chambers of sulphuric acid works.* The washed deposit is boiled with conc.  $\text{Na}_2\text{SO}_3$  till it is black (from formation of  $\text{PbS}$ ), and the liquid, which contains  $\text{Na}_2\text{SeO}_3$ , is filtered into dil.  $\text{HClAq}$ , whereby  $\text{Se}$  is ppd. This process is repeated several times (Böttger, *J. pr.* 94, 439). Or the washed deposit is digested at  $80^\circ\text{--}100^\circ$  with fairly conc.  $\text{KCNaq}$  until the red colour of the liquid has changed to grey, the liquid is filtered, the residue washed with boiling water till  $\text{HClAq}$  ceases to produce a reddish opalescence in the washings, and excess of  $\text{HClAq}$  is added to the filtrate and washings, whereby  $\text{Se}$  is ppd. ( $\text{KCNaq} + \text{Se} = \text{KCNSeaq}$ ;  $\text{KCNSeaq} + \text{HClAq} = \text{KClAq} + \text{HCNSeaq} + \text{Se}$ ). The ppd.  $\text{Se}$  is dissolved in  $\text{HNO}_3\text{Aq}$ , the solution is evaporated (slowly, to prevent loss of  $\text{SeO}_2$ ) to dryness, the  $\text{SeO}_2$  is sublimed in a tube of hard glass in a stream of dry dust-free air, the sublimate is dissolved in water,  $\text{HClAq}$  is added, and  $\text{Se}$  is ppd. by  $\text{SO}_2$  (Oppenheim, *J. pr.* 71, 266).

$\text{Se}$ , as prepared by reducing cold  $\text{H}_2\text{SeO}_3\text{Aq}$ , is a red amorphous powder; an amorphous vitreous variety is obtained by melting ppd.  $\text{Se}$  and cooling very rapidly by pouring on to a porcelain plate (Hittorf, *P.* 84, 214; Rammelsberg, *P.* 152, 151; Regnault, *A. Ch.* [3] 46, 257); a black crystalline variety of  $\text{Se}$  is prepared by allowing conc.  $\text{K}_2\text{SeAq}$  or  $\text{Na}_2\text{SeAq}$  to stand in air until a crust forms on the surface (*H., l.c.*; *R., l.c.*), also by crystallising any form of  $\text{Se}$  from  $\text{Se}_2\text{Cl}_2$  (Rathke, *A.* 152, 181); a red crystalline variety is prepared by slowly and repeatedly heating a solution of  $\text{Se}$  in  $\text{CS}_2$  in a sealed tube to somewhat under  $100^\circ$ , and allowing to cool (*R., l.c.*; Rathke, *A.* 152, 181), also by subliming amorphous  $\text{Se}$  (Bornträger, *D. P. J.* 242, 55); a grey metal-like variety is prepared by very slowly heating amorphous or red crystalline  $\text{Se}$  to  $96^\circ\text{--}97^\circ$  (*H., l.c.*; *R., l.c.*; Fabre, *C. R.* 103, 53). According to Schutze (*J. pr.* [2] 32, 390) a colloidal soluble form of  $\text{Se}$  is obtained by reducing  $\text{H}_2\text{SeO}_3\text{Aq}$  by  $\text{SO}_2$ ; no acid must be present. The colloidal  $\text{Se}$  remains in solution, colouring the liquid dark red. The solution is not changed by boiling but on adding an acid or a salt  $\text{Se}$  is ppd. in red flocks.

*Properties.*— $\text{Se}$  exists in several, probably in five, forms.

#### I. Amorphous selenion; sol. in $\text{CS}_2$ .—

(i.) *Red-powdery amorphous Se* forms sealing-wax-red flocks, or when dried at a low temperature a dark-red powder; when formed by reduction of hot  $\text{H}_2\text{SeO}_3\text{Aq}$  it appears as a black powder (Hittorf, *P.* 84, 214). *S.G.* at  $20^\circ = 4.3$  (Rammelsberg, *P.* 152, 151; Schaffgotsch, *P.* 90, 66);  $4.2$  (Rathke, *A.* 152, 131). This variety is a non-conductor of electricity (Hittorf, *l.c.*). It is sol.  $\text{CS}_2$ ; *S.* at b.p. of  $\text{CS}_2$  ( $46.6^\circ$ ) =  $1$ , at  $0^\circ = 0.16$  (Mitscherlich, *J.* 1856. 314); according to Rammelsberg (*l.c.*) the solubility in  $\text{CS}_2$  varies much. For *S.H. v.* beginning of this article. Petersen (*Z. P. C.* 8, 601) gives *H.O.* of this variety [ $\text{Se}, \text{O}^\circ$ ] = 57,250, and at vol. 184; the change from this form to any other form of  $\text{Se}$  is attended with contraction and the production of a small quantity of heat. For action of heat *v. infra.*

(ii.) *Amorphous vitreous Se* forms a black lustrous solid, appearing red in thin layers. *S.G.*  $4.282$  at  $20^\circ$  (Schaffgotsch, *J. pr.* 43, 308; 60, 312). Sol. in  $\text{CS}_2$ . No fixed melting-point; when heated it softens at  $60^\circ$ , and becomes gradually less viscous till at  $250^\circ$  it is quite liquid; if this liquid is rapidly cooled, the vitreous variety is re-formed (Hittorf, *l.c.*; Draper a. Moss, *C. N.* 33, 1). Heated very slowly to  $96^\circ\text{--}97^\circ$  this variety changes to metallic  $\text{Se}$ , with production of heat (*R., l.c.*; Regnault, *A. Ch.* [3] 46, 257; Fabre, *C. R.* 103, 53).

II. *Crystalline selenion; insol. in  $\text{CS}_2$ .*—(i.) *Black crystalline Se.* Small, microscopic, glittering leaflets. *S.G.*  $4.8$  (*R., l.c.*);  $4.76$  to  $4.78$  at  $15^\circ$  (Mitscherlich, *J.* 1855. 314). Insol.  $\text{CS}_2$ . *H.C.* [ $\text{Se}, \text{O}^\circ$ ] = 55,820; at vol. = 16.5; change from amorphous  $\text{Se}$  to this form is accompanied by slight production of heat and contraction (Petersen, *Z. P. C.* 8, 601).

(ii.) *Red crystalline Se.* Small, thin, transparent, lustrous crystals; in thicker layers appears black and opaque. *S.G.*  $4.46$  to  $4.5$  at  $15^\circ$  (*R., l.c.*; *M., l.c.*; Rathke, *l.c.*). Melts at  $217^\circ$  (*H., l.c.*; *D. a. M., l.c.*). Insol. in  $\text{CS}_2$ . Petersen (*l.c.*) gives *H.C.* [ $\text{Se}, \text{O}^\circ$ ] = 56,200; and at vol. = 17.7. This variety is a conductor of electricity, the conductivity increasing with increase of temp. and also by exposure to light. (For details, *v. infra.*) When heated to  $c. 110^\circ$  this variety becomes black. The crystals are monoclinic, ratio of axes =  $1.62:1.1:1.6$  (*M., l.c.*; Regnault, *l.c.*); isomorphous with monoclinic *S* (*R., l.c.*). For *S.H. v.* beginning of this article.

(iii.) *Grey metallic Se.* Lustrous, grey, metal-like, granular solid, resembling grey pig-iron; somewhat malleable (Regnault, *l.c.*). Insol. in  $\text{CS}_2$ . *S.G.*  $4.4$  to  $4.5$  (*R., l.c.*). Melts at  $217^\circ$  (*H., l.c.*); on cooling, the vitreous variety is chiefly formed, but if the cooling is stopped at  $210^\circ$  after a time there is a sudden rise to  $217^\circ$ , and the whole solidifies in the metallic form. All varieties of  $\text{Se}$  are sol.  $\text{Se}_2\text{Cl}_2$  and  $\text{SeEt}_2$ .

*Action of heat on selenion.* Any one of the crystalline varieties of  $\text{Se}$  melts at  $217^\circ$ ; when the molten  $\text{Se}$  is allowed to cool slowly it gradually becomes less soft, a thermometer placed in the cooling substance continuously falls and shows no point of rest (Hittorf, *l.c.*; Regnault, *l.c.*); the final product is crystalline  $\text{Se}$ , but if the cooling is caused to take place rapidly the amorphous vitreous variety is formed; if the cooling is stopped at  $210^\circ$ , and that temperature is maintained for some time, there is a sudden rise to  $217^\circ$  and the  $\text{Se}$  again solidifies in the crystalline (metallic) form. When amorphous  $\text{Se}$  is heated it softens at  $c. 60^\circ$ , and becomes gradually less viscous until at  $250^\circ$  it is quite liquid; if the heating is very gradual, there is a sudden evolution of heat at  $96^\circ\text{--}97^\circ$  (Regnault, *l.c.*), found temperature rise to  $200^\circ\text{--}230^\circ$ , and the metallic variety is produced.  $\text{Se}$  boils at  $676^\circ\text{--}683^\circ$ , forming a reddish-yellow vapour, the *V.D.* of which does not become constant until  $600^\circ\text{--}700^\circ$  above the b.p.

*Effects of light and heat on the electrical conductivity of crystalline selenion.* Amorphous  $\text{Se}$  does not conduct electricity; but when heated rapidly it begins to conduct at  $165^\circ\text{--}175^\circ$ , and conductivity increases until it attains a

maximum at c.  $217^{\circ}$  (Draper & Moss, *C. N.* 83, 1). Crystalline Se conducts, the conductivity increasing proportionally with increase of temperature to  $217^{\circ}$ , after which it decreases and reaches a minimum at  $250^{\circ}$  (Hittorf, *P.* 84, 214; D. a. M., *l.c.*). If Se is heated for a considerable time to  $200^{\circ}$  and is then allowed to cool, conductivity decreases as temperature rises and increases as temperature falls (W. Siemens, *P.* 159, 117). This observation seems to show that at c.  $200^{\circ}$  a variety of Se is formed which behaves like a metal, and that on cooling this form remains mixed with the ordinary crystalline variety, so that the conductivity depends on the relative quantities of the two forms, and therefore on the temperature (*cf.* Kalischer, *W.* 31, 101). The electrical conductivity of crystalline Se increases enormously when the Se is exposed to light (Sale, *Pr.* 21, 283; Smith, *B.* 6, 204; Rosse, *P. M.* [4] 47, 161; Forssmann, *W.* 2, 513). Adams and Day (*Pr.* 24, 163) found that the resistance of Se varied directly as the square root of the intensity of the source of light; also that light caused an electric current in Se from the less to the more illuminated part (*Pr.* 25, 113; *cf.* Bidwell, *C. N.* 52, 191).

Se may be sublimed and distilled *in vacuo*, or in an indifferent gas (Schuller, *J.* 1884, 1550); heated in air it is burnt to  $\text{SeO}_2$ . Se dissolves in conc.  $\text{H}_2\text{SO}_4$ , forming  $\text{SeSO}_3$ , and is pptd. again on adding water; Se is sol. in alkali solutions, forming alkali selenides; also in  $\text{KCN}$ aq, in alkaline sulphite solutions, in  $\text{SeCl}_2$ ,  $\text{Se}_2\text{Br}_2$ , and  $\text{SeEt}_2$ ; the amorphous varieties are al. sol.  $\text{CS}_2$ .

Se resembles S and Te in its chemical character; it is somewhat less negative than S and more negative than Te; it shows distinct analogies with Cr, Mo, W, and U (*v.* OXYGEN GROUP OF ELEMENTS, vol. iii. p. 705; and CHROMIUM GROUP OF ELEMENTS, vol. ii. p. 168).

The atomic wt. of Se has been determined (1) by analysing  $\text{SeCl}_4$  (Berzelius, *P.* 8, 21 [1818]); (2) by analysing  $\text{K}_2\text{SeO}_4$  (Mitscherlich & Nitzsch, *P.* 9, 627 [1827]); (3) by oxidising Se to  $\text{SeO}_2$ , by reducing  $\text{SeO}_2$  to Se, and by analysing  $\text{BaSeO}_3$  (Sace, *A. Ch.* [3] 21, 119 [1847]); (4) by analysis of  $\text{HgSe}$  (Erdmann & Marchand, *J. pr.* 55, 202 [1849]); (5) by converting Se into  $\text{SeCl}_4$  (Dumas, *A. Ch.* [3] 55, 186 [1859]); (6) by reducing  $\text{SeO}_2$  to Se and by analysing  $\text{Ag}_2\text{SeO}_3$  (Pettersson & Ekman, *B.* 9, 1210 [1876]); (7) by determining S.H. of Se (Regnault, *A. Ch.* [3] 46, 257); (8) by determining V.D. of, and analysing,  $\text{SeH}_2$ ,  $\text{SeO}_2$ ,  $\text{Se}_2\text{Cl}_2$ ,  $\text{SeCl}_4$ , and  $\text{SeBrCl}_2$ .

The molecular wt. of Se has been found by determining the V.D. of Se at  $860^{\circ}$ , c.  $1000^{\circ}$ , and c.  $1400^{\circ}$ ; the values at  $1400^{\circ}$  agree with the formula  $\text{Se}_2$ .

The atom of Se is divalent in the gaseous molecule  $\text{SeH}_2$ , and tetravalent in the gaseous molecules  $\text{SeCl}_4$  and  $\text{SeBrCl}_2$ .

**Reactions and Combinations.**—1. *Water and ozone* produce  $\text{H}_2\text{SeO}_4$  (Maillet, *C. R.* 94, 860, 1186). Water alone does not react at  $160^{\circ}$  (Cross & Higgin, *C. J.* 35, 249).—2. *Conc. sulphuric acid* dissolves Se on warming, forming  $\text{H}_2\text{SeO}_4$ , and some  $\text{H}_2\text{SeO}_3$ , and giving off  $\text{SO}_2$ . *Fuming sulphuric acid* forms a greenish solution containing  $\text{SeSO}_3$  (*v.* *Thio-oxide*, p. 441); on boiling  $\text{H}_2\text{SeO}_4$  is formed and  $\text{SO}_2$  evolved

(Divers & Shimmose, *B.* 18, 1209).—3. *Hot conc. nitric acid* oxidises Se to  $\text{H}_2\text{SeO}_4$ , with evolution of NO. *Hydrochloric acid* does not react with Se.—4. Se dissolves in *alkali solutions*, forming alkali selenides; *fusion with alkalis* produces the same compounds.—5. *Fusion with nitre or potassium chlorate* forms  $\text{K}_2\text{SeO}_4$ .—6. *Potassium cyanide solution* dissolves Se to  $\text{KCNSeAq}$ .—7. *Solutions of alkali or alkaline earth sulphites* dissolve Se, forming thioselenates (Rathke & Zschiesche, *J. pr.* 92, 141; Uelsmann, *A.* 116, 123; *v.* also THIOSELENATES, p. 434).—8. Se vapour passed over heated *lead fluoride* forms Se fluoride (Knox, *Pr. Irish Acad.* 1841, 299).—9. Se combines with *oxygen* to form  $\text{SeO}_2$ , when heated in O or air.—10. Se combines with *chlorine, bromine, and iodine* at the ordinary temperature.—11. Heated to low redness with *hydrogen*,  $\text{H}_2\text{Se}$  is formed (Uelsmann, *A.* 116, 122).—12. *Phosphorus* combines at the ordinary temperature.—13. Se combines with *arsenic and antimony*, by heating the elements together.—14. Selenides of most metals are formed by heating Se with *metals* (*v.* SELENIDES, p. 436). Sometimes the combination is effected without heat, under the influence of light (*v.* Bidwell, *P. M.* [5] 20, 178; Moss, *C. N.* 33, 203).—15. Se dissolves in molten *sulphur*, but no definite compounds are formed in this way.—16. With *sulphuric anhydride* Se combines to form  $\text{SeSO}_3$  (*v.* *Thio-oxide*, p. 441).

**Selenium, acids of.** *Selenhydric acid*  $\text{H}_2\text{Se}$ , vol. ii. p. 724; *selenic acid*  $\text{H}_2\text{SeO}_4$ , p. 435; *selenous acid*  $\text{H}_2\text{SeO}_3$ , p. 445; *Selenocyanhydric acid*  $\text{HCNSe}$ , vol. ii. p. 348; also *Selenocyanic acid*, this vol. p. 443; *salts of thioselenic acids*,  $\text{H}_2\text{SeSO}_3$  and  $\text{H}_2\text{SeS}_2\text{O}_6$ , are known, p. 434; and *salts of selenosamic acids*,  $\text{Se}(\text{NH}_2)\text{OM}'$  and  $2\text{SeO}(\text{NH}_2)\text{OH}\cdot\text{OM}'$ , have been isolated, p. 446.

**Selenium, antimonide of;** *v.* vol. i. p. 283, ANTIMONY, Combinations of, No. 6.

**Selenium, arsenides and arsenosulphides of;** *v.* vol. i. p. 303, ARSENIC, Combinations of, No. 7.  
**Selenium, boride of.** A yellow-grey solid is formed by strongly heating amorphous B in a stream of  $\text{H}_2\text{Se}$ ; the solid is decomposed by water with rapid evolution of  $\text{H}_2\text{Se}$  (Sabatier, *C. R.* 112, 865). As S. gives the formula  $\text{B}_2\text{S}_3$  to the boron sulphide formed by passing  $\text{H}_2\text{S}$  over B, it is probable that the Se compound has the composition  $\text{B}_2\text{Se}_3$ .

**Selenium, bromides of.** Two compounds of Se and Br are known,  $\text{Se}_2\text{Br}_2$  and  $\text{SeBr}_2$ ; both are formed by the direct union of the elements. Both are decomposed by heat, but they are more stable towards heat than the corresponding S compounds (Evans & Ramsay, *C. J.* 45, 62). As the V.D. of neither has been determined, the formulæ are not necessarily molecular; but from the analogy of  $\text{Se}_2\text{Cl}_2$  and  $\text{SeCl}_4$ , which formulæ represent the compositions of gaseous molecules of these chlorides, it is probable that the mol. wts. of the bromides correspond with the formulæ  $\text{Se}_2\text{Br}_2$  and  $\text{SeBr}_2$ .

**SELENIUM BROMIDE  $\text{Se}_2\text{Br}_2$ .** (*Selenium monobromide*.) Formulæ probably molecular, from analogy of  $\text{Se}_2\text{Cl}_2$ . To 15·9 parts powdered Se covered with three times its weight of dry  $\text{CS}_2$ , 16 parts Br are gradually added; after a time the  $\text{CS}_2$  is distilled off; and  $\text{Se}_2\text{Br}_2$  remains as a thin oily liquid, having a dark reddish-brown

colour (appearing black in a thickish layer), and an unpleasant smell resembling that of  $S_2Cl_2$  (Serullas, *A. Ch.* [2] 35, 349; Schneider, *P.* 128, 327). A thin layer of  $Se_2Br_2$  transmits rose-red light; the absorption spectrum has been examined by Gernez (*C. R.* 74, 1190). S.G. of  $Se_2Br_2$  = 3.604 at 15°. Br is given off on heating, then a little  $SeBr_4$ , and at 225°-230° most of the  $Se_2Br_2$  distils over, and finally some Se is obtained (Schneider, *l.c.*).  $Se_2Br_2$  dissolves in all proportions in  $CS_2$ , less easily in  $CHCl_3$ ,  $EtBr$ , and  $EtI$ . It sinks in *water*, and then decomposes to  $H_2SeO_4$ ,  $HBr$ , and Se. *Absolute alcohol* forms  $SeBr_4$  (which remains dissolved) and Se.  $Se_2Br_2$  dissolves Se (c. 22 p.c.), on adding  $CS_2$  the Se separates. Br is absorbed by  $Se_2Br_2$ , with formation of  $SeBr_4$ . A solution of  $Se_2Br_2$  in  $CS_2$ , shaken with dry  $AgCN$  forms a little Se cyanide (Schneider, *P.* 123, 634).

**SELENIUM BROMIDE  $SeBr_4$ .** (*Selenion tetrabromide*.) Formula probably molecular, from analogy of  $SeCl_4$ . To a solution of 1 part  $Se_2Br_2$  in  $CS_2$ ,  $1\frac{1}{2}$  parts Br are gradually added, the  $SeBr_4$ , which separates is allowed to stand in contact with the  $CS_2$  for some days, whereby it becomes crystalline, and the  $CS_2$  is distilled off; the compound obstinately retains some  $CS_2$ . By heating to 75°-80° Br is given off, and the  $SeBr_4$ , containing  $Se_2Br_2$ , sublimes in black, lustrous, six-sided leaflets, mixed with a little pure  $SeBr_4$  in dark-orange crystals, and  $Se_2Br_2$  remains (Schneider, *P.* 129, 450).  $SeBr_4$  is also obtained by dissolving 1 part powdered Se in 10-12 parts Br, pressing the crystalline mass between filter-paper, and removing excess of Br by gently warming.  $SeBr_4$  dissolves in  $CS_2$ ,  $CHCl_3$ , and  $EtBr$ ; it dissolves with decomposition in alcohol, also in  $HCl$  aq.  $SeBr_4$  is very hygroscopic; in moist air it gives Br and  $Se_2Br_2$ ; in much water it forms  $H_2SeO_4$  and  $HBr$  aq. Combines with  $SO_2$  to form  $SeCl_4 \cdot SO_2$  (*v. SELENIUM TRIOXYCHLORIDE*, p. 441). Forms compounds with KBr and  $NH_4Br$ ,  $K_2SeBr_6$  and  $(NH_4)_2SeBr_6$  (*v. Muthmann a. Schäfer*, *B.* 26, 1008).

**Selenion, bromochlorides of.** Two compounds of Se, Br, and Cl were obtained by Evans and Ramsay (*C. J.* 45, 68) by the interactions of  $Se_2Cl_2$  and Br, and  $Se_2Br_2$  and Cl. The bromochlorides thus formed are  $SeBrCl_3$  and  $SeBr_2Cl$ .

**SELENIUM TRIBROMOCHLORIDE  $SeBr_2Cl$ .** Orange, hygroscopic crystals formed by adding 2.1 parts Br, in  $CS_2$  to 1 part  $Se_2Cl_2$ , crystallising from  $CS_2$ , and gently warming in a current of air to remove adhering  $CS_2$  ( $Se_2Cl_2 + 3Br_2 = 2SeBr_2Cl$ ). Decomposes when heated, giving off Br; as V.D. at 200° was c. half that calculated for  $SeBr_2Cl$ , dissociation is probably complete at that temperature.

**SELENIUM BROMOTRICHLORIDE  $SeBrCl_3$ .** Mol. w. 264.66. V.D. at 179° and 754 mm. pressure = 131.5; dissociation begins at c. 190°-200°. Yellow-brown crystals; obtained by passing Cl into  $Se_2Br_2$  in  $CS_2$ , washing the pp. with  $CS_2$ , and drying in a current of warm air. Gives off Br when heated above c. 190°, and yields sublimate of  $SeBr_4$ .

**Selenion, carbide of, *v.* CARBON SELENIDE**, vol. i. p. 693.

**Selenion, chlorides of.** Two chlorides are formed by passing Cl over heated Se; using an excess of Se the product is  $Se_2Cl_2$ , and with an excess of Cl the product is  $SeCl_4$ . Attempts to form  $SeCl_3$ , corresponding with  $SnCl_3$ , have been unsuccessful.

**SELENIUM CHLORIDE  $Se_2Cl_2$ .** (*Selenion monochloride. Selenion selenochloride*.) Mol. w. 228.34. V.D. 110 at 200°-250° (Evans a. Ramsay, *C. J.* 45, 62; Chabridé, *Bl.* [3] 2, 803). S.G. 2.906 at 17.5° (Divers a. Shimosé, *C. J.* 45, 198). Boiling begins at c. 145°, but no definite b.p. can be given (E. a. R., *l.c.*). H.F. [ $Se_2Cl_2$ ] = 22,150 (*Th.* 2, 405).

**Formation.**—1. By passing Cl over excess of heated Se.—2. By heating  $SeCl_4$  with Se at 100° (Borzelius, *P.* 9, 225).—3. By passing HCl into a solution of Se in fuming  $H_2SO_4$  (Divers a. Shimosé, *C. J.* 45, 194, 198).

**Preparation.**—HCl gas is passed into a solution of Se in fuming  $H_2SO_4$ , till a deep-red liquid is deposited and the mother-liquor is yellowish-brown; the mother-liquor is then poured off, the red liquid is dissolved in fresh fuming  $H_2SO_4$ , and HCl is passed in; this process is repeated again; finally, the red liquid is digested, in a closed vessel, with dry KCl (to remove  $H_2SO_4$ ) and decanted (D. a. S., *l.c.*). The reactions are probably (1)  $2SeSO_4 + 2HCl = SeSO_4 \cdot SeCl_2 + H_2SO_4$ ; (2)  $SeSO_4 \cdot SeCl_2 + HCl = Se_2Cl_2 + SO_4 \cdot Cl \cdot OH$  (D. a. S.).

**Properties, Reactions, and Combinations.**— $Se_2Cl_2$  is a heavy, deep-red liquid, smelling something like  $S_2Cl_2$ ; S.G. 2.906 at 17.5°; somewhat volatile at ordinary temperatures, giving off orange-coloured vapour at 100°, beginning to boil at c. 145°, but exhibiting no fixed b.p. (E. a. R., *l.c.*). V.D. determined at c. 200° gave results agreeing with  $Se_2Cl_2$ . For absorption spectrum of vapour *v.* Gernez, *C. R.* 74, 1190.  $Se_2Cl_2$  is easily sol.  $CS_2$ ,  $CHCl_3$ ,  $C_2H_6$ , and  $CCl_4$ . It is slowly decomposed by  $H_2O$ ,  $EtOH$ , and  $Et_2O$ ; a solution in  $CS_2$ , shaken with water gives  $H_2SeO_4$  aq,  $HCl$  aq, and Se. Warm  $Se_2Cl_2$  dissolves Se freely; on cooling the Se is partly ppd. in the metal-like form (Rathke, *A.* 152, 181).  $Se_2Cl_2$  is decomposed by shaking with Hg or Ag (D. a. S., *l.c.*); with P it gives  $PCl_5$  and Se (Baudrimont, *A. Ch.* [4] 2, 5).  $Se_2Cl_2$  combines with  $PCl_5$  to form a yellow substance (B., *l.c.*).

**SELENIUM CHLORIDE  $SeCl_4$ .** (*Selenion tetrachloride*.) Mol. w. 220.28. V.D. at 180° = 110 (Evans a. Ramsay, *C. J.* 45, 65). H.F. [ $SeCl_4$ ] = 46,160 (*Th.* 2, 405).

**Formation.**—1. By heating Se, or  $Se_2Cl_2$ , in excess of Cl.—2. By heating  $SeO_2$  with  $PCl_5$  (*v. Preparation*).—3. By the action of  $SOCl_2$  on  $SeOCl_2$ .

**Preparation.**—To 13 parts  $PCl_5$  in a long-necked flask 7 parts  $SeO_2$  are added little by little, the reaction being allowed to cease after each addition before more  $SeO_2$  is added ( $SeO_2 + PCl_5 = SeOCl_2 + POCl_3$ ); the mass becomes liquid and then suddenly solidifies ( $3SeOCl_2 + 2POCl_3 = 3SeCl_4 + P_2O_5$ ); excess of  $POCl_3$  is now removed by heating the flask while a rapid stream of dry  $CO_2$  is passed through it; a wide tube is then fitted by a cork into the neck of the flask, and the flask is placed in a tray containing hot sand (if the flask is

allowed to cool the condensing  $P_2O_5$  may cause it to crack (Michaelis, *J. Z.* 6, 79).

**Properties, Reactions, and Combinations.** A slightly yellow crystalline solid; volatilises when heated, without melting, in yellow vapours. Evans & Ramsay (*C. J.* 45, 66) found V.D. at  $180^\circ$  to be 110, agreeing with the formula  $SeCl_2$ ; dissociation to  $Se_2Cl_2$  and Cl began at c.  $210^\circ$ , and at  $350^\circ$  c. 66 p.c. was decomposed. Clausnizer (*B.* 11, 2007) got the value 57 for V.D. at  $218^\circ$ , at which temperature E. & R.'s value was c. 86; at  $368^\circ$  Chabrié (*Bl.* [3] 2, 803) obtained the number 57, which agrees fairly with the results of E. & R.  $SeCl_2$  is nearly insol.  $CS_2$ . In moist air  $SeOCl_2$  and HCl are produced (Weber, *P.* 108, 615); water forms  $H_2SeO_3$  and  $HClAq$ .  $H_2S$  produces HCl and Se sulphide;  $SO_2$  has no action.  $NH_3Aq$  produces Se, N, and H at ordinary temperatures, and N selenide at a low temperature (Verneuil, *Bl.* [2] 38, 548). Dry  $NH_3$  combines with  $SeCl_2$  at  $-20^\circ$ , forming a very unstable compound, probably  $SeCl_2 \cdot 4NH_3$  (V., *l.c.*). With  $PCl_5$  the compound  $SeCl_2 \cdot 2PCl_5$  is formed (Baudrimont, *A. Ch.* [4] 2, 5).

Selenion, chlorobromides of, v. SELENIUM BROMOCHLORIDES, p. 439.

Selenion, cyanide of; v. CYANOGEN SELENIDE, vol. ii. p. 358.

Selenion, fluoride of. No definite compound of Se and F has been isolated. According to Knox (*Pr. Irish Acad.* 1841. 299) a fluoride of Se sublimes when Se vapour is passed over molten  $PbF_2$ .

Selenion, haloid compounds of. Se combines with the halogens to form two types of compounds,  $Se_2X_2$  and  $SeX_2$  (the fluorides have not been examined); the formulae are probably molecular, as the V.D.s of  $Se_2Cl_2$  and  $SeCl_2$  have been determined. The compounds  $Se_2X_2$ , where  $X = Cl$  or  $Br$ , are liquids at ordinary temperatures; the other compounds are solids. All the compounds are fairly easily decomposed by heat, but less easily than the corresponding S haloid compounds.

Selenion, hydride of; v. HYDROGEN SELENIDE, vol. ii. p. 724.

Selenion, hydroxides of. The hydroxides of Se,  $SeO(OH)_2$ , and  $SeO_2(OH)_2$  are acids; v. SELENIUS ACID, p. 445, and SELENIC ACID, p. 435.

Selenion, iodides of. Two compounds of Se and I are known,  $Se_2I_2$  and  $SeI_4$ , corresponding with the bromides and chlorides.

SELENIUS IODIDE  $SeI_2$ . (*Selenion monoxide*.) Formula probably molecular, from analogy of  $SeCl_2$ . Formed by heating the elements together in the ratio  $Se:I(1:1.61)$ ; also by heating  $SeBr_2$  and  $EtI$  at  $100^\circ$  in a sealed tube (Schneider, *P.* 129, 627). Crystalline, steel-grey, somewhat metal-like solid; melting to a dark-brown liquid at  $68^\circ-70^\circ$ . Decomposed to Se and I by continued heating at  $100^\circ$ ; also by solvents of I. Water forms  $H_2SeO_3Aq$ ,  $HIAq$ , and Se.

SELENIC IODIDE  $SeI_4$ . (*Selenion tetra-iodide*.) Formula probably molecular, from analogy of  $SeCl_4$ . Formed by heating together Se and I in the ratio  $Se:I(1:6.44)$ ; also by mixing  $SeBr_2$  and  $EtI$  in the ratio  $SeBr_2:4EtI$ , the  $SeI_4$  separates after a little. Best prepared by adding

$HIAq$  to conc.  $H_2SeO_3Aq$  as long as a pp. is produced; the pp. is washed, pressed, and dried over  $H_2SO_4$  (Schneider, *l.c.*). A dark-grey solid, melting at  $75^\circ-80^\circ$  to a blackish-brown liquid. Gives up all I when heated to c.  $100^\circ$ , or treated with solvents of I; slowly decomposed by water. Attempts to form an *iodochloride of selenium* were unsuccessful (v. Evans & Ramsay, *C. J.* 45, 70).

Selenion, nitride of; v. NITROGEN SELENIDE, vol. iii. p. 570.

Selenion, oxides of. Only one oxide of Se has been isolated with certainty; this oxide is  $SeO_2$ . Berzelius thought that an oxide  $SeO$  was formed, along with  $SeO_2$ , by heating Se in air or O, by heating Se and  $SeO_2$ , and by the partial oxidation of Se sulphide by  $HNO_3$ . According to Chabrié (*A. Ch.* [6] 20, 202) Se takes up O approximately corresponding with that required to form  $SeO$ , when heated in air to  $180^\circ$ . Attempts to prepare  $SeO$  have failed. By passing gaseous  $SeO_2$  and O over hot spongy Pt, von Gerichten (*A.* 168, 214) obtained a white sublimate that dissolved in water with a hissing sound, forming  $H_2SeO_3$ , but Cameron & Macallan (*Pr.* 46, 32) failed to confirm this result; C. a. M. (*l.c.*) did not get  $SeO_2$  by passing O over hot Pt sponge mixed with Se, nor by the action of ozone on  $SeO_2$ , nor by heating selenate of Sb, Bi, Fe, Pb, Hg, or Ag. By heating dry  $H_2SeO_3$  with  $P_2O_5$  in a closed flask they got a trace of a crystalline solid, analyses of which pointed to the composition  $SeO_2$ . A solution of Se in  $H_2SeO_3$  perhaps contains  $Se_2O_3$  (v. SELENIC ACID, *Reactions*, No. 6, p. 436).

SELENIUM DIOXIDE  $SeO_2$ . (*Selenious oxide, Selenious anhydride*.) Mol. w. not determined. S.G. 3.9538 at  $15^\circ$  (Cameron & Macallan, *Pr.* 46, 27; Clausnizer, *A.* 196, 265).  $[Se_2O_4] = 57,250$  from amorphous Se; 55,820 from black crystalline Se; 56,200 from red crystalline Se (Petersen, *Z. P. C.* 8, 601). Melts at  $340^\circ$  in a sealed tube; at ordinary pressure volatilises without melting, slowly at  $250^\circ$ , rapidly at  $280^\circ$  (Chabrié, *A. Ch.* [6] 20, 202; C. a. M., *l.c.*). For absorption-spectrum of  $SeO_2$  vapour v. Gernez (*C. R.* 74, 803).

**Preparation.**—1. Se is placed in the lower part of a V-tube with one limb longer than the other, and the longer limb drawn to a fine opening; the shorter limb is connected with a gas-holder, from which a stream of dry O is passed into the V-tube; the tube is heated till the Se burns; the  $SeO_2$  condenses in the longer limb of the tube. —2. Se is dissolved in conc.  $HNO_3Aq$ , the solution is evaporated to dryness, best in a retort (solidification occurs suddenly, with evolution of heat); the dry  $H_2SeO_3$  is heated in the retort till sublimation begins, then let cool, and dissolved in water; the solution is ppd. by  $BaOAc$ ; the solution, after filtering, is evaporated to dryness, and the residue is heated, when  $SeO_2$  sublimes; traces of  $H_2SeO_3$  and  $H_2SO_4$  are thus removed, excess of  $BaO$  remains in the residue (Thomsen, *B.* 2, 598; cf. Wohlwill, *A.* 114, 176; Fischer, *P.* 67, 412).

**Properties and Reactions.**—Long, white, lustrous, four-sided needles (for m.p. &c. v. beginning of this article). 1. Slowly withdraws water from moist air, forming  $H_2SeO_3$ ; dissolves in water, forming same acid, with disappearance of

heat,  $[\text{SeO}_2, \text{Aq}] = -920$  (Tf. 2, 405).—2. Sl. sol. boiling *acetic anhydride*, crystallising unchanged; heated to  $180^\circ$ – $200^\circ$  oxidation of the  $\text{Ac}_2\text{O}$  occurs (to  $\text{CO}_2$ , &c.) and Se separates (Hinsberg, A. 260, 40).—3. Dissolves in *aqueous acetic acid*,  $\text{H}_2\text{SeO}_3$ , separating on cooling (H., l.c.).—4. Dissolves in *alcohol* of 96 p.c., and is re-obtained on evaporation over  $\text{H}_2\text{SO}_4$  (H., l.c.). 5. Reacts with *phosphoric chloride* to give  $\text{SeCl}_4$ ,  $\text{P}_2\text{O}_5$ , and  $\text{POCl}_3$ ; heated with *phosphoryl chloride* gives  $\text{SeOCl}_2$  and  $\text{P}_2\text{O}_5$  (Michaelis, J. Z. 6, 79).—6. Heated with *sodium chloride* yields  $\text{SeOCl}_2$  and  $\text{Na}_2\text{SeO}_3$  (Cameron a. Macallan, Pr. 46, 35).—7. Heated with *selenium tetrachloride* in a closed tube produces  $\text{SeOCl}_2$ ; with  $\text{SeBr}_4$ , probably forms  $\text{SeOBr}_2$  (Schneider, P. 129, 450). 8. Decomposed by dry *ammonia* to  $\text{H}_2\text{O}$ , Se, and N; when  $\text{NH}_3$  is passed into  $\text{SeO}_2$  in absolute alcohol,  $\text{SeO}(\text{NH}_4)\text{ONH}_2$  is formed (v. SELENOSAMIC ACIDS, SALTS or, p. 446).—9. Heated with dry  $\text{HCN}$  and  $\text{Ac}_2\text{O}$ , Se cyanide is probably formed (Hinsberg, A. 260, 40).—10. *Hydriodic acid* reduces  $\text{SeO}_2$  to Se and  $\text{H}_2\text{O}$ , even at  $10^\circ$ .—11.  $\text{SeO}_2$  and *sulphur dioxide* do not react at any temperature (Schulze, J. pr. [2] 32, 390).—12. The compounds  $\text{K}_2\text{SeBr}_4$  and  $(\text{NH}_4)_2\text{SeBr}_4$  are produced by dissolving  $\text{SeO}_2$  in *hydrobromic acid* and adding *potassium* or *ammonium bromide* (v. Muthmann a. Schäfer, B. 26, 1008).

**Combinations.**—1. According to Ditte (A. Ch. [5] 10, 82),  $\text{SeO}_2$  combines with dry *hydrogen chloride* to form two compounds, one of which,  $\text{SeO}_2 \cdot 2\text{HCl}$ , is liquid, and the other,  $\text{SeO}_2 \cdot 4\text{HCl}$ , is solid, at the ordinary temperature. With *hydrogen bromide*  $\text{SeO}_2 \cdot 4\text{HBr}$  is formed, and when this is kept very cold and  $\text{HBr}$  is passed over it, D. says that  $\text{SeO}_2 \cdot 5\text{HBr}$  is produced. *Hydrogen fluoride* is said also to combine with  $\text{SeO}_2$ , but the product has not been examined.—2. With *alkali halides* the compounds  $\text{MX}_2 \cdot 2\text{SeO}_2 \cdot 2\text{H}_2\text{O}$  are formed (Muthmann a. Schäfer, B. 26, 1008).—3. Hinsberg (A. 260, 40) described a compound with *alcohol*,  $\text{SeO}_2 \cdot \text{C}_2\text{H}_5\text{O}$ , obtained by evaporating  $\text{SeO}_2$  in absolute alcohol over  $\text{CaCl}_2$ .—4. Large white crystals of the compound  $\text{SeO}_2 \cdot \text{SO}_2$  are obtained by warming  $\text{SeO}_2$  and pure *sulphuric anhydride* to  $100^\circ$ , distilling off excess of  $\text{SO}_2$  at  $60^\circ$ – $70^\circ$ , and allowing to cool. At  $100^\circ$  the compound gives up  $\text{SO}_2$  (Weber, B. 19, 1385).

**SELENIUM THIO-OXIDE  $\text{SeSO}_2$ .** (*Selenium sulphoxide. Selenium-sulphur trioxide.*) Mol. w. not determined. Magnus (P. 10, 491) noticed that Se dissolved in fuming  $\text{H}_2\text{SO}_4$  to produce a green solution; Weber (P. 156, 531) separated and analysed the green compound, and gave it the formula  $\text{SeSO}_2$ . Divers a. Shimosé (C. J. 45, 201) further examined this substance. Powdered Se is placed in liquid  $\text{SO}_2$ ; heat is given off, and a dark-green liquid is formed; after a time the whole solidifies; after warming to  $30^\circ$ – $40^\circ$  for a few minutes the liquid part is drained off, and the adhering  $\text{SO}_2$  is removed by the use of a Sprengel pump (for details v. D. a. S. on  $\text{TeSO}_2$ , C. J. 43, 324).  $\text{SeSO}_2$  is a green solid, which may be heated to c.  $35^\circ$  without change; decomposition begins at c.  $40^\circ$ , and at c.  $120^\circ$   $\text{SO}_2$  and O are rapidly evolved and Se separates; by heating slowly *in vacuo* it changes to a yellow powder, which D. a. S. think to be a modification of the thio-oxide.  $\text{SeSO}_2$  is sol. conc.  $\text{H}_2\text{SO}_4$ ; on adding much water Se is pptd.,

and  $\text{H}_2\text{SeO}_3$  and  $\text{H}_2\text{SO}_4$  go into solution.  $\text{HCl}$  reacts with  $\text{SeSO}_2$  in  $\text{H}_2\text{SO}_4$  to form  $\text{SeCl}_4$  and  $\text{SO}_2 \cdot \text{Cl} \cdot \text{OH}$  (v. SELENIOSULFURIC ACID, Preparation, p. 439). Schulz-Sellaack (B. 4, 118) observed that the vapours of  $\text{SO}_2$  react with Se to form a yellow powder.

**Selenium, oxyacids of, and their salts.** The oxyacids of Se are *selenious acid*  $\text{H}_2\text{SeO}_3$  (v. p. 445) and *selenic acid*  $\text{H}_2\text{SeO}_4$  (v. p. 435); salts of the *thioselenic acids*  $\text{H}_2\text{SeSO}_3$  and  $\text{H}_2\text{SeS}_2\text{O}_3$  have been isolated (v. p. 484); and salts of the *selenosamic acids*  $\text{SeO}(\text{NH}_4)\text{OH}$  and  $2\text{SeO}(\text{NH}_4)(\text{OH})$ , are known (v. p. 439).

**Selenium, oxybromide of.** By melting together  $\text{SeO}_2$  and  $\text{SeBr}_4$ , Schneider (P. 129, 450) obtained needles which were probably  $\text{SeOBr}_2$ , corresponding with  $\text{SeOCl}_2$  formed in a similar way.

**Selenium, oxychlorides of.** The oxychloride of Se,  $\text{SeOCl}_2$ , corresponds with *sulphuryl chloride*  $\text{SOCl}_2$ ; an oxychloride containing Se and S, and corresponding with  $\text{S}_2\text{O}_2\text{Cl}_4$ , has also been isolated.

**SELENYL CHLORIDE  $\text{SeOCl}_2$ .** (*Selenium oxychloride.*) Mol. w. not determined.

**Preparation.**—1. Equivalent weights of  $\text{SeCl}_4$  and  $\text{SeO}_2$  are heated in a sealed tube to  $150^\circ$ , and the product is purified by repeated distillation (Weber, P. 118, 615).—2.  $\text{SeO}_2$  and  $\text{PCl}_5$  are brought together in the ratio  $\text{SeO}_2 \cdot \text{PCl}_5$ ;  $\text{SeOCl}_2$  and  $\text{POCl}_3$  are produced, but the heat evolved suffices to cause a secondary reaction, which yields  $\text{SeCl}_4$  and  $\text{P}_2\text{O}_5$ , so that very little  $\text{SeOCl}_2$  can be obtained by this method (Michaelis, J. Z. 6, 79; cf. SELENIC CHLORIDE, Preparation, p. 439).—3. By distilling  $\text{SeO}_2$  and  $\text{NaCl}$  in the ratio  $\text{SeO}_2 \cdot \text{NaCl}$  (Cameron a. Macallan, Pr. 46, 35).

**Properties.**—A yellowish liquid, fuming in the air, boiling at  $179.5^\circ$ , and solidifying below  $0^\circ$  to colourless crystals, which melt at  $10^\circ$  (M., l.c.).

**Reactions and Combinations** (M., l.c.).—1. Water decomposes  $\text{SeOCl}_2$ , forming  $\text{H}_2\text{SeO}_3$  and  $\text{HClAq}$ .—2. *Ammonia* produces  $\text{SeO}_2$ , Se, N,  $\text{NH}_4\text{Cl}$ .—3. *Sulphuryl chloride* produces  $\text{SeCl}_4$  and  $\text{SO}_2$ .—4. *Phosphoryl chloride* forms  $\text{SeCl}_4$  and  $\text{P}_2\text{O}_5$  (v. Preparation of selenic chloride, p. 439).—5. With *phosphorous chloride*  $\text{POCl}_3$ ,  $\text{SeCl}_4$  and  $\text{Se}_2\text{Cl}_2$  are produced.—6.  $\text{SeOCl}_2$  combines with *stannic chloride* to form  $3\text{SeOCl}_2 \cdot \text{SnCl}_4$ ; also with *titanic chloride* and *antimonic chloride* to form  $2\text{SeOCl}_2 \cdot \text{TiCl}_4$  and  $2\text{SeOCl}_2 \cdot \text{SbCl}_5$  (Weber, P. 125, 325).

**SELENIUM, THIO-OXYCHLORIDE OF,  $\text{SeSO}_2\text{Cl}_2$ .** (*Pyrothioselenyl chloride. Selenium sulphoxytetrachloride.*) Mol. w. not determined.

**Formation.**—1. By the interaction of  $\text{SO}_2$  and  $\text{SeCl}_4$  (H. Rose, P. 44, 315).—2. By dissolving  $\text{SeCl}_4$  in Nordhausen sulphuric acid (Clausnizer, B. 11, 2007).—3. By heating  $\text{SO}_2\text{Cl}_2$  and  $\text{SeOCl}_2$  in a sealed tube to  $170^\circ$ – $180^\circ$  (C., l.c.).—4. By the interaction of  $\text{SO}_2 \cdot \text{OH} \cdot \text{Cl}$  and  $\text{SeO}_2$ ,  $\text{SeOCl}_2$ , or  $\text{SeCl}_4$  (C., l.c.).

**Preparation.**— $\text{SeCl}_4$  and  $\text{SO}_2 \cdot \text{OH} \cdot \text{Cl}$  are warmed together in the ratio  $\text{SeCl}_4 \cdot 2(\text{SO}_2 \cdot \text{OH} \cdot \text{Cl})$  till the  $\text{SeCl}_4$  is quite dissolved:

$\text{SeCl}_4 + \text{SO}_2 \cdot \text{OH} \cdot \text{Cl} = \text{SeSO}_2\text{Cl}_2 + \text{Cl}_2$   
(Excess of  $\text{SO}_2 \cdot \text{OH} \cdot \text{Cl}$  is needed to hasten the reaction and to serve as a solvent.) The reddish solution solidifies on cooling; the white needles are

separated by pressing between porous plates, and dried over  $\text{H}_2\text{SO}_4$ .

**Properties and Reactions.**—Small white needles; unchanged *in vacuo* or on gentle warming; deliquesces in moist air; melts at  $165^\circ$  and boils at  $183^\circ$ ; V.D. at  $209^\circ = 48.5$ , calculated for  $\text{SeSO}_2\text{Cl}_2 = 150$ ; dissociation has therefore occurred, perhaps thus:  $2\text{SeSO}_2\text{Cl}_2 = 2\text{SO}_2 + \text{Se}_2\text{Cl}_2 + 3\text{Cl}_2$  (C. l.c.). Decomposed by water, at once, to  $\text{H}_2\text{SO}_4\text{Aq}$ ,  $\text{H}_2\text{SeO}_3\text{Aq}$ , and  $\text{HClAq}$ .

**Selenium, phosphides of; v. PHOSPHORUS SELENIDES**, p. 144.

**Selenium, sulphides of.** The only compound of Se and S that has been isolated is  $\text{SeS}$ . Divers a. Shimidzu (C. J. 47, 446) say that this is the only compound of the two elements that exists, but Rathke (B. 18, 1534) considers that others exist, although none but  $\text{SeS}$  has been obtained in a state of purity. Se and S may be melted together in all proportions, but no compound is produced (Bettendorff a. von Rath, P. 139, 329; Rathke, P. 141, 590). Isomorphous mixtures of the two elements crystallise from solutions of Se and S in  $\text{CS}_2$  (B. a. von R., l.c.). The pp. formed by passing  $\text{H}_2\text{S}$  into  $\text{H}_2\text{SeO}_3$  contains Se and S in the ratio  $\text{SeS}_2$ , but it is a mixture of  $\text{SeS}$  with S (H. Rose, P. 107, 186; D. a. S., l.c.; Rathke, B. 18, 1534). The pp. containing Se and S in the ratio  $\text{Se}_2\text{S}$  obtained by passing  $\text{H}_2\text{Se}$  into  $\text{H}_2\text{SO}_4$  is merely a mixture (D. a. S., l.c.).

**SELENIUM MONOSULPHIDE  $\text{SeS}$ .** Mol. w. not determined. Very dilute  $\text{H}_2\text{SeO}_3\text{Aq}$ , cooled to  $0^\circ$ – $5^\circ$ , is saturated with  $\text{H}_2\text{S}$ , which is first passed through a flask filled with pieces of ice; the yellow pp. which forms is washed, dried *in vacuo*, moistened with  $\text{CS}_2$ , and allowed to stand for some days till the mass becomes crystalline, the  $\text{CS}_2$  withdrawing S;  $\text{CS}_2$  is added to the crystals, after a few minutes the  $\text{CS}_2$  is decanted, and the residue is washed with  $\text{C}_2\text{H}_6$  and then with alcohol.  $\text{SeS}$  forms small, orange-yellow, lustrous tablets; S.G. 3.056 at  $0^\circ$ , 3.035 at  $52^\circ$ ; S.H. 1274. On heating it melts, gives off S vapour, and then vapour of S and Se. Sol.  $\text{CS}_2$ , but not crystallisable therefrom by evaporation; insol. water and ether (Ditte, C. R. 73, 625, 660).

**Selenium, sulphoxide of; v. Selenium thio-oxide**, under SELENIUM OXIDES, p. 441.

**Selenium, sulphonylchloride of; v. Selenium thio-oxychloride**, under SELENIUM OXYCHLORIDES, p. 441.

**Selenium, thio-oxychloride of; v. Selenium oxychlorides**, p. 441.

M. M. P. M.

#### SELENIUM, ORGANIC COMPOUNDS OF.

**Methyl selenide or Selenium methide  $\text{Me}_2\text{Se}$ .** Mol. w. 109. ( $58^\circ$ ). Formed by distilling a solution of barium methyl sulphate with  $\text{K}_2\text{Se}$  (Wöhler a. Dean, A. 97, 5) or of  $\text{KMeSO}_4$  with  $\text{Na}_2\text{Se}$  (C. L. Jackson, A. 179, 1). Heavy oil with nasty smell. Burns with bluish flame.  $\text{PtCl}_4$  forms  $(\text{Me}_2\text{Se})_2\text{PtCl}_4$ , crystallising from alcohol in yellow plates. Conc.  $\text{HNO}_3$  forms  $(\text{Me}_2\text{SeO})\text{HNO}_3$  [ $91^\circ$ ], whence  $\text{HClAq}$  produces  $\text{Me}_2\text{SeCl}_4$  [ $60^\circ$ ], while  $\text{HBrAq}$  gives  $\text{Me}_2\text{SeBr}_4$  [ $82^\circ$ ] and  $\text{KIaq}$  ppts.  $\text{Me}_2\text{SeI}_4$ .

**Methylo-iodide  $\text{Me}_2\text{SeI}_4$ . Tri-methyl-selenonium iodide.** Yields  $(\text{Me}_2\text{SeCl})_2\text{PtCl}_4$ ,

crystallising from water in dark-red octahedra (Jackson, B. 7, 1277).

**Di-methyl diselenide  $\text{Me}_2\text{Se}_2$ .** Formed from  $\text{KMeSO}_4$  and  $\text{K}_2\text{Se}_2$  (W. a. D.; Rathke, A. 152, 211). Heavy reddish-yellow oil, with unpleasant odour, sol.  $\text{HNO}_3\text{Aq}$ .

**Methane selenic acid  $\text{CH}_3\text{SeO}_2\text{H}$ .** [ $122^\circ$ ]. Formed by oxidising  $\text{Me}_2\text{Se}_2$  with  $\text{HNO}_3$  (W. a. D.). Deliquescent crystals, v. sol. alcohol. Gives with  $\text{HCl}$  crystalline  $\text{CH}_3\text{SeO}_2\text{Cl}$ .— $\text{AgA}'$ : prisms.

**Ethyl selenide  $\text{Et}_2\text{Se}$ .** ( $108^\circ$ ). (Rathke; Pieverling, A. 185, 331). Oil, without unpleasant odour.  $\text{HCl}$  added to its solution in dilute  $\text{HNO}_3$  ppts.  $\text{Et}_2\text{SeCl}_2$ , whence  $\text{NH}_3\text{Aq}$  forms  $(\text{Et}_2\text{Se})_2\text{OCl}_2$  (Joy, A. 86, 35).

**Ethyl iodide  $\text{Et}_2\text{SeI}$ .** Crystalline. Converted by moist  $\text{Ag}_2\text{O}$  into a strongly alkaline base which forms crystalline salts.— $(\text{Et}_2\text{SeCl})_2\text{ZnCl}$  thin plates.— $(\text{Et}_2\text{SeCl})_2\text{PtCl}_4$ .

**Di-ethyl diselenide  $\text{Et}_2\text{Se}_2$ .** ( $186^\circ$ ). Liquid with disgusting odour.  $\text{HCl}$  added to its solution in dilute  $\text{HNO}_3$  gives monoclinic crystals of  $\text{C}_2\text{H}_5\text{SeO}_2\text{Cl}$ .

**Ethane selenic acid  $\text{Et}_2\text{SO}_2\text{H}$ .** Yields with  $\text{HCl}$  monoclinic crystals of  $\text{C}_2\text{H}_5\text{SeO}_2\text{Cl}$ .

**Ethyl selenhydrate  $\text{EtSeI}$ .** **Selenion-mercaptan.** Formed from  $\text{KSeH}$  and  $\text{Ca}(\text{EtSO}_4)_2$  (Siemens, A. 61, 360). Heavy oil, boiling much below  $100^\circ$  and having an unpleasant odour. Reacts with  $\text{HgO}$ .

**Ethyl selenite  $\text{SeO}(\text{OEt})_2$ .** ( $184^\circ$ ). S.G. 1.49. Formed from  $\text{Ag}_2\text{SeO}_3$  and  $\text{EtI}$ , and got also by heating  $\text{SeOCl}_2$  with  $\text{NaOEt}$  and dry ether at  $180^\circ$  (Michaelis, A. 241, 158). Thick liquid, miscible with water and alcohol. The **chloride  $\text{SeO}(\text{OEt})\text{Cl}$**  [ $10^\circ$ ] ( $175^\circ$ ), formed from  $\text{SeOCl}_2$  and alcohol, crystallises in needles.

**Selenide of carbon  $\text{CSe}_2$ .** Formed in small quantity by passing a mixture of  $\text{CCl}_4$  and  $\text{H}_2\text{Se}$  through a red-hot tube (Rathke, A. 152, 199). Pungent yellow liquid. Converted by alcoholic potash into  $\text{EtO.CSe}_2\text{K}$ , crystallising in yellow needles, v. sol. water and alcohol.

**Selenido-di-acetic acid  $\text{Se}(\text{CH}_2\text{CO}_2\text{H})_2$ .** Formed from ammonium chloro-acetate and alcoholic  $(\text{NH}_4)_2\text{Se}$  (Ulrich, B. 8, 773). Monoclinic tables.— $(\text{NH}_4)_2\text{A}'$ : insol. alcohol — $\text{CuA}'$ : bluish-green pp.

**Amide.**—Formed from  $\text{ClCH}_2\text{CONH}_2$  and alcoholic  $(\text{NH}_4)_2\text{Se}$ . Prisma, m. sol. cold water.

**Di-phenyl selenide  $\text{SePh}_2$ .** S.G. 1.450. V.D. 8.17 (calc. 8.09). Formed, together with selenophenol and  $\text{SePh}_2\text{C}_6\text{H}_4\text{Cl}$  ( $240^\circ$ – $250^\circ$  *in vacuo*), from  $\text{SeCl}_4$  and benzene in presence of  $\text{AlCl}_3$  (Chabrie, C. R. 109, 183; Bl. [2] 50, 133; [3] 2, 788). Oil. Boils at  $227^\circ$  under a few cm. pressure. Bromine forms  $\text{Se}(\text{C}_6\text{H}_4\text{Br})_2$  [ $112^\circ$ ], crystallising from alcohol in colourless hexagonal plates.  $\text{H}_2\text{O}_2$  in presence of  $\text{HCl}$  and a current of air, forms  $\text{Se}(\text{C}_6\text{H}_4\text{Cl})_2\text{C}_6\text{H}_4\text{OH}$  [ $145^\circ$ ] converted by  $\text{HNO}_3$  into a crystalline product [ $188^\circ$ ].

**Phenyl selenhydrate  $\text{C}_6\text{H}_5\text{SeH}$ .** **Selenophenol.** [ $60^\circ$ ]. Formed from benzene,  $\text{SeCl}_4$ , and  $\text{AlCl}_3$  (Chabrie, C. R. 109, 183; Bl. [3] 2, 788). Sol. alcohol, insol. water.

**Tetra-methyl-di-amido-di-phenyl-selenide  $\text{Se}(\text{C}_6\text{H}_4\text{NMe}_2)_4$ .** [ $124^\circ$ ]. Formed from  $\text{SeOCl}_2$  and di-methyl-aniline in ether (Godchaux, B. 24, 765). Yellowish needles, m. sol. cold alcohol

and ether.— $B''H_2SO_4$ . [55°]. Colourless needles, v. s. sol. water.— $B''2C_6H_5(NO_2)_2OH$ . [135°]. Yellow plates.

**Tetra-ethyl-di-amido-di-phenyl-selenide**  $Se(C_2H_5NEt)_4$ . [83°]. Formed from  $SeOCl_2$  and  $PhNEt_2$  in ether. Silky needles, v. s. sol. hot ether and alcohol.— $B''H_2Cl_2$ . [73°].— $B''2C_6H_5(NO_2)_2OH$ . [135°]. Yellow plates and needles.

**Di-phenyl-selenone**  $SeOPh_2$ . (230° at 65 mm.). S.G. 1.2148. Formed, together with the compound  $PhSeO(C_2H_5Cl)$  [94°], from  $SeOCl_2$ , benzene, and  $AlCl_3$ . Amber-yellow liquid. Not attacked by cold  $HNO_3$ . Bromine-water yields  $SeO(C_2H_5Br)_2$  [120°].  $H_2O_2$ ,  $HCl$ , and a current of air form  $SeO(C_2H_5Cl)_2$  [159°].

**Phenyl seleno-carbimide**  $Ph.NC.Se$ . Formed by shaking  $Na_2Se$  with the chloride of phenyl-carbamine,  $PhNCCl_2$ , and ether for a day, filtering, distilling with steam, and drying the oil *in vacuo* over  $H_2SO_4$  (Stolte, B. 19, 2350). Pale yellowish-red oil, v. sol. alcohol and ether.

**Phenyl-seleno-urea**  $NHPh.CSe.NH_2$ . [182°]. Formed by passing  $NH_3$  into  $Ph.NC.Se$  dissolved in ether, and also by the action of  $H_2Se$  on phenyl-cyanamide in benzene (Stolte, B. 19, 1579, 2350). Crystals (from alcohol).

**Di-phenyl-seleno-urea**  $CSO(NHPh)_2$ . [186°]. Formed from aniline and phenyl seleno-carbimide (Stolte, B. 19, 2351). Crystals (from alcohol), sl. sol. ether.

**Selenaldine**  $C_6H_5NSe_2$ . Formed by passing  $SeH_2$  into an aqueous solution of aldehyde-ammonia in absence of air (Wöhler a. Liebig, A. 61, 11). Colourless crystals, with slight odour, sl. sol. water, v. sol. alcohol and ether. Its solutions are turned brown by air.

**Amido-selenazole**  $C_6H_5N_2Se$  i.e.  $Se.C(NH_2)_2 \gg N$ . **Selenazylamine**. [121°].  $CH:CH$ . Formed by warming seleno-urea with di-chloro-di-ethyl oxide and aqueous  $NaOEt$  (G. Hofmann, A. 250, 308). White needles, v. sol. alcohol and ether, m. sol. benzene and water. Decomposed by prolonged boiling with water.— $B'_2H_4PtCl_6$ : orange-red pp.

**Acetyl derivative**  $C_6H_5AcN_2Se$ . [c. 210°]. Needles.

**Oxy-amido-selenazole**  $Se.C(NH_2)_2 \gg N$ . **Selenohydantoin**. [190°]. Formed by boiling seleno-urea with chloro-acetic acid and alcohol (G. Hofmann, A. 250, 312). Thick crystals, m. sol. hot water and alcohol, insol. ether.— $B'HCl$ : needles.

**Di-oxy-selenazole**  $Se.C(OH)_2 \gg N$ . [147°].  $CH:C(OH)$ . Formed by boiling oxy-amido-selenazole with  $NaOHAq$  (Hofmann). Prisms, v. sol. alcohol, m. sol. water.

**Amido-methyl-selenazole**  $Se.C(NH_2) \gg N$ .  $CH:CHMe$ . [80°]. Formed from seleno-urea and chloro-acetone (G. Hofmann, A. 250, 305). Needles, v. sol. alcohol and ether. Alkaline in reaction.— $B'HCl$ : prisms (from water).— $B'_2H_4PtCl_6$ : orange-red crystalline pp.

**Acetyl derivative**  $C_6H_5AcN_2Se$ . [122°]. Needles (from benzene), sl. sol. water.

**Amido-methyl-selenazole carboxylic acid**  $Se.C(NH_2) \gg N$ . [195°]. Formed by heating seleno-urea with chloro-acetoacetic ether (G. Hofmann, A. 250, 309). Needles, m. sol. water, v. sol. alcohol and ether.— $HA'HCl$ : plates, v. s. sol. water.

**Acetyl derivative**  $C_6H_5AcN_2SeO_2$ . [220°]. Needles, almost insol. hot water.

**Amido-phenyl-selenazole**  $C_6H_5N_2Se$  i.e.  $Se.C(NH_2)_2 \gg N$ . [132°]. Formed from bromo- $CH:CPh$  acetophenone and seleno-urea (G. Hofmann, A. 250, 307). Needles or prisms, insol. water, sol. alcohol and acids.— $B'HIHBr$ : yellowish plates, sl. sol. cold water.

**Di-phenyl-selenazole**  $C_6H_5N_2Se$  i.e.  $Se.CPh \gg N$ . [99°]. Formed from  $\omega$ -bromo- $CH:CPh$  acetophenone and seleno-benzamide (G. Hofmann, A. 250, 317). Plates, v. sol. alcohol and ether. Its salts are decomposed by water.— $B'_2H_4PtCl_6$ : pale-yellow pp.

**Phenyl-methyl-selenazole**  $C_6H_5NSe$  i.e.  $Se.CPh \gg N$ . (283° at 737 mm. Formed from  $PhCSe.NH_2$  [126°] and chloro-acetone (G. Hofmann, A. 250, 316). Yellow oil.— $B'_2H_4PtCl_6$ : pale-yellow needles.

**Phenyl-methyl-selenazole carboxylic acid**  $C_6H_5SeNO_2$  i.e.  $Se.CPh \gg N$ . [207°].  $CO_2H.C:CHMe$ . Formed by saponifying its ether, which is got from seleno-benzamide and chloro-acetoacetic ether (Hofmann, A. 250, 318). Small needles (from benzene), m. sol. alcohol.— $AgA'$ .

**Ethyl ether**  $EtA'$ . [124°]. Plates. **Seleno-benzoic acid**. **Amide**  $C_6H_5CSe.NH_2$ . [126°]. Formed by passing  $H_2Se$  into an alcoholic solution of benzonitrile made slightly alkaline with  $NH_3$  (Dechend, B. 7, 1273; G. Hofmann, A. 250, 314). Golden needles (from water or ether). Reacts with  $\alpha$ -chloro-ketones, forming selenazoles; e.g.  $X.CO.CHCl.X + CPh(SeH):NH = H_2O + Se.CX \gg NHCl$ .

**Seleno-benzoic aldehyde v. BENZYLIDENE SELENIDE.**

**Selenocyanic acid**  $HSeCN$ . The K salt is got by fusing  $KFeCy_3$  (3 pts.) with Se (1 pt.) (Crookes, A. 78, 177; cf. Berzelius, S. J. 81, 60). The free acid is obtained, in solution, by decomposing the lead salt by  $H_2S$ . It is decomposed by acids into Se and  $HCy$ .  $FeCl_3$  does not give a red colour, but ppts. Se. Iodine added to a solution of  $KSeCN$  ppts.  $KO_2N_2Se$ . Air containing a little chlorine passed over a 10 p.c. solution of  $KSeCN$  forms a red crystalline pp.  $KSeC_2N_3$ , aq changing to yellow  $Se_2Cy_3$ , which separates from chloroform in yellow plates, and is decomposed by water into  $HCy$ ,  $SeO_2$ , and Se, and yields *in vacuo* at 108° a crystalline sublimate of  $Se_2Cy_3$ , decomposed by hot water into  $HCy$ ,  $SeO_2$ , and Se (Verneuil, C. R. 108, 144). Alcohol converts  $KSeC_2N_3$  into Se and  $KSeC_2N_3$ , which forms brown crystals, sol. alcohol.

**Salts.—KA'.** Formed as above, and also by dissolving Se in aqueous  $KCy$  (Wöhler; Schiellerup, A. 109, 125; G. Hofmann, A. 250, 296). Very deliquescent needles, alkaline to litmus.— $NH_4A'$  (Cameron a. Davy, C. N. 44,

68).— $\text{KA'HgCl}_2$ : white pp.— $\text{KA'HgBr}_2$ .— $\text{KA'HgI}_2$ .— $\text{KHgA}'$ : prisms.— $\text{KHgA}'$ .— $\text{HgA}'$ : olive-green pp.— $\text{HgA}'$ : felt-like mass of yellowish crystals.— $\text{AgA}'_2\text{HgCl}_2$ .— $\text{PbA}'_2$ : lemon-yellow needles (from water).— $\text{K}_2\text{PtA}'_4$ : Dark-red scales (Clarke, *B.* 11, 1826).— $\text{AgA}'$ : Satiny crystals, blackened by light. Converted by  $\text{IO}_2$  into volatile crystalline  $\text{SeCy}_2$  (Linnemann, *A.* 120, 86).

*Methyl ether*  $\text{MeA}'$ . (158°). Yellow oil (Stolte, *B.* 19, 1577).

*Allyl ether*  $\text{C}_2\text{H}_5\text{A}'$ . Oil.

*Methylene ether*  $\text{CH}_2\text{A}'$ . [132°]. Formed from  $\text{MeI}$  and alcoholic  $\text{KSeCN}$  (Proskauer, *B.* 7, 1281). Rhombohedra (from alcohol).  $\text{HNO}_3$  forms  $\text{CH}_2(\text{SeO}_2\text{H})_2$ .

*Ethylene ether*  $\text{C}_2\text{H}_4\text{A}'$ . [128°].  $\text{HNO}_3$  forms, on boiling, deliquescent  $\text{C}_2\text{H}_4(\text{SeO}_2\text{H})_2$ , which yields  $\text{BaA}'$ , sol. hot water.  $\text{KOH}$  yields diethylene tetraselenide [131°].

*Propylene ether*

$\text{CH}_3\text{CH}(\text{SeCN})\text{CH}_2(\text{SeCN})$ . [66°]. Formed by heating  $\text{KSeCN}$  with propylene bromide and alcohol (Hagelberg, *B.* 23, 1091). White crystals.

*Trimethylene ether*

$\text{CH}_2(\text{SeCN})\text{CH}_2\text{CH}_2(\text{SeCN})$ . [51°]. Converted by  $\text{KOH}$  into trimethylene diselenide [55°].

*Benzyl ether* v. vol. i. p. 602.

*Selenocyno-acetic acid*  $\text{CH}_2(\text{SeCN})\text{CO}_2\text{H}$ . [85°]. Formed from chloro-acetic acid and potassium selenocyanide (G. Hofmann, *A.* 250, 800). Yellowish needles (from ether and chloroform), v. e. sol. water and alcohol.— $\text{BaA}'_2$ : amorphous.

*Selenocyno-acetoacetic ether*

$\text{CH}_3\text{CO}\text{CH}(\text{SeCN})\text{CO}_2\text{Et}$ . Formed from chloro-acetoacetic ether and  $\text{KSeCN}$  (H.). Liquid.

*Selenocyno-acetone*  $\text{CH}_3\text{CO}\text{CH}_2\text{SeCN}$ .

Formed from chloro-acetone and  $\text{KSeCN}$  (H.). Yellowish oil. Gives an oily phenyl-hydrazide and an oxim. Not more sol. alkalis than water.

*Selenocyno-acetophenone*

$\text{C}_6\text{H}_5\text{CO}\text{CH}_2\text{SeCN}$ . [85°]. Formed by boiling  $\alpha$ -bromo-acetophenone with alcohol and  $\text{KSeCN}$  (Hofmann). Crystalline.

*Selenocyno-ethyl-phthalimide*

$\text{C}_6\text{H}_4\text{O}_2\text{N}\text{CH}_2\text{CH}_2\text{SeCN}$ . [125°]. Formed by heating bromo-ethyl-phthalimide with  $\text{KSeCy}$  and alcohol (Coblentz, *B.* 24, 2133). Crystalline mass. Converted by boiling dilute caustic potash into  $\text{Se}_2(\text{C}_6\text{H}_4\text{NH}\text{CO}\text{C}_6\text{H}_4\text{CO}_2\text{H})_2$  [119°], which forms yellowish crystals and is converted by  $\text{HCl}$  at 180° into  $\text{Se}_2(\text{C}_6\text{H}_4\text{NH}_2)_2$ , which yields  $\text{B}^2\text{HCl}$  [188°] and  $\text{B}^2\text{C}_2\text{H}_4\text{N}_2\text{O}$  [178°], both being crystalline.

*$\gamma$ -Selenocyno-propyl-phthalimide*

$\text{C}_6\text{H}_4\text{O}_2\text{N}\text{CH}_2\text{CH}_2\text{CH}_2\text{SeCN}$ . [102°]. Formed by heating bromo-propyl-phthalimide with  $\text{KSeCN}$  and alcohol (Coblentz, *B.* 24, 2134). Converted by boiling dilute (10 p.c.)  $\text{KOH}$  into crystalline  $\text{Se}_2(\text{C}_6\text{H}_4\text{NH}\text{CO}\text{C}_6\text{H}_4\text{CO}_2\text{H})_2$  [84°], whence  $\text{HCl}$  at 180° forms  $\text{Se}_2(\text{C}_6\text{H}_4\text{NH}_2)_2$ , which yields  $\text{B}^2\text{HCl}$  [170°] and  $\text{B}^2\text{C}_2\text{H}_4\text{N}_2\text{O}$  [165°].

*$\alpha$ -Selenocyno- $\alpha$ -toluic acid. Nitrile*

$\text{CH}_2(\text{SeCN})\text{C}_6\text{H}_4\text{CN}$ . *o-Cyano-benzyl selenocyanide*. [121°]. Formed by warming the nitrile  $\text{CH}_2\text{Cl}\text{C}_6\text{H}_4\text{CN}$  with  $\text{KSeCN}$  (Drory, *B.* 24, 2664). Long brownish needles (from alcohol) or prisms (from benzene). Converted by dilute

$\text{H}_2\text{SO}_4$  into  $\text{Se}(\text{CH}_2\text{C}_6\text{H}_4\text{CN})_2$  [110°].  $\text{HClAq}$  at 100° forms  $\text{Se}$  and *o*-cyano-benzyl chloride.

*Selenocyanuric acid*  $\text{H}_2\text{Se}_2\text{C}_3\text{N}_3$ . Formed from  $\text{Cl}_2\text{C}_3$  and  $\text{Na}_2\text{Se}$  (Stolte, *B.* 19, 1578).

*Methyl ether*. [174°].

*Seleno-phthalimidine*  $\text{C}_6\text{H}_4\text{C}(\text{NH})\text{CH}_2\text{Se}$ .

Formed from  $\text{CH}_2(\text{SeCN})\text{C}_6\text{H}_4\text{CN}$  and conc.  $\text{H}_2\text{SO}_4$  (Drory, *B.* 24, 2566). Sol. alcohol.

*Reactions*.—1.  $\text{NaOH}$  forms the compound  $\text{Se}(\text{CH}_2\text{C}_6\text{H}_4\text{CN})_2$ , crystallising in needles [110°], sol. alcohol and  $\text{CS}_2$ , and converted by  $\text{HCl}$  at 160° into  $\text{Se}$  and phthalide.—2. When steam is blown through a mixture of selenophthalimidine, alcohol, and  $\text{KOH}$  there is formed seleno-phthalide  $\text{C}_6\text{H}_4\text{C}(\text{CO})\text{CH}_2\text{Se}$ , crystallising in broad plates [58°], insol. water, sol. alcohol.—3. Alcoholic potash and  $\text{MeI}$  form  $\text{CH}_2(\text{SeMe})\text{C}_6\text{H}_4\text{CN}$  (180°–200°).

*Salts*.— $\text{B}^1\text{HCl}$ : needles, slightly sol. water and alcohol.— $\text{B}^2\text{H}_2\text{PtCl}_6$ . Orange powder.— $\text{B}^3\text{C}_2\text{H}_4\text{N}_2\text{O}$ .— $\text{B}^4\text{HBr}$ . [264°]. Needles: sl. sol. water.— $\text{B}^5\text{HI}$  (?) [223°]. Formed by heating  $\text{CH}_2(\text{SeCy})\text{C}_6\text{H}_4\text{CN}$  with  $\text{HIAq}$  at 100°. Dark-violet needles.—*Sulphate* [145°–150°].

*Piaselenole*  $\text{C}_6\text{H}_4\text{C}(\text{N})\text{Se}$ . [76°]. Formed

from *o*-phenylene-diamine and an aqueous solution of selenious acid (Hinsberg, *B.* 22, 2897). Needles, v. sol. alcohol and ether, sl. sol. water. Its salts are yellow and decomposed by much water with separation of the base. Iodine forms a green periodide.

*Amido-piaselenole*  $\text{C}_6\text{H}_3(\text{NH}_2)_2\text{N}_2\text{Se}$ . [150°]. Formed by adding  $\text{H}_2\text{SeO}_3$  to a cool solution of tri-amido-benzene hydrochloride and  $\text{NaOAc}$  (Hinsberg, *B.* 22, 2898). Brownish-red needles, sl. sol. water, m. sol. alcohol.  $\text{SnCl}_4$  separates  $\text{Se}$ .— $\text{B}^1\text{HCl}$ : reddish-brown needles, sl. sol.

*Oxy-piaselenole. Ethyl derivative*

$\text{C}_6\text{H}_3(\text{OEt})_2\text{N}_2\text{Se}$ . [104°]. This is formed from  $\text{C}_6\text{H}_3(\text{OEt})(\text{NH}_2)_2$  and aqueous  $\text{H}_2\text{SeO}_3$ . Needles forming a yellowish-red solution in  $\text{H}_2\text{SO}_4$ .

*Methyl-piaselenole*  $\text{CH}_3\text{CH}(\text{C}_6\text{H}_4\text{C}(\text{N})\text{Se})\text{CH}_3$ . [73°].

(267° uncor.). Formed from tolylene-diamine and aqueous  $\text{SeO}_2$  at 80° (Hinsberg, *B.* 22, 863). Needles, sl. sol. cold water.  $\text{SnCl}_4$  yields tolylene-*o*-diamine and  $\text{Se}$ . Does not react with nitrous acid or with  $\text{Ac}_2\text{O}$ .— $\text{B}^2\text{H}_2\text{PtCl}_6$ .

*Chloro-methyl-piaselenole*  $\text{C}_6\text{H}_4\text{ClMeN}_2\text{Se}$ .

[150°]. Formed by warming *o*-tolylene-diamine with  $\text{SeO}_2$  and conc.  $\text{HClAq}$  (Hinsberg, *B.* 23, 1395). Small needles, volatile with steam.

*Naphthopiaselenole*  $\text{C}_{10}\text{H}_7\text{C}(\text{CH}_2\text{C}_6\text{H}_4\text{C}(\text{N})\text{Se})\text{CH}_2\text{C}_6\text{H}_4\text{C}(\text{N})\text{Se}$ .

[129°]. Formed from ( $\alpha\beta$ )-naphthylene-diamine sulphate, aqueous  $\text{NaOAc}$ , and  $\text{SeO}_2$  (Hinsberg, *B.* 22, 866). Needles, sl. sol. water, m. sol. alcohol, v. sol. ether. Conc.  $\text{H}_2\text{SO}_4$  gives an intense yellow colour.  $\text{SnCl}_4$  and  $\text{HCl}$  give  $\text{Se}$  and naphthylene-diamine.

*Seleno-urea*  $\text{CSe}(\text{NH}_2)_2$ . [c. 200°]. S. 11 at 19°. S. (alcohol) 3 at 18°. Formed by passing  $\text{H}_2\text{Se}$  into a 2 p.c. solution of cyanamide in ether (Verneuil, *C. R.* 99, 1154; 100, 1296; *Bl.* [2] 43, 58, 583). White needles, v. sol. hot water, sl. sol. alcohol and ether. Its solutions are decomposed by light, especially in presence of an alkali, with separation of

**selenium.** In presence of air and HClAq it yields  $(\text{CSeN}_2\text{H}_4)_2\text{O}_2\text{HCl}$ , which forms brown crystals with violet reflex, converted by baryta-water into Se, seleno-urea, and cyanamide. The compound  $(\text{CSeN}_2\text{H}_4)_2\text{O}_2\text{HBr}$  may be formed in like manner. When the 'oxy-triselenourea' hydrochloride is allowed to stand in the acid liquid in which it is formed, it changes into yellow crystalline  $(\text{CSeN}_2\text{H}_4)_2\text{Cl}_2$ . HIAq converts selenourea into  $(\text{CSeN}_2\text{H}_4)_2\text{I}_2$ .  $\text{H}_2\text{SO}_4$  added to a saturated solution of selenourea forms scarlet crystals converted by heating with alcohol (100 pts.) and  $\text{H}_2\text{SO}_4$  (4 pts.) at  $50^\circ$  into  $(\text{CSeN}_2\text{H}_4)_2\text{OH}_2\text{SO}_4$ , crystallising in pearly plates.

Ethylene- $\psi$ -seleno-urea  $\text{C}_2\text{H}_4\text{N}_2\text{Se}$  i.e.

$\text{CH}_2\text{Se} > \text{C:NH}$ . Formed by evaporating a solution of bromo-ethyl-amine hydrobromide (8 g.) with  $\text{KSeCy}$  (5 g.) to dryness on a water-bath (Baringer, B. 23, 1003). Unstable. Converted by bromine-water into ethylene- $\psi$ -urea.— $\text{B'HBr}$ .  $[170^\circ]$ . Needles.— $\text{B}'_2\text{H}_2\text{PtCl}_6$ .— $\text{B}'_2\text{C}_2\text{H}_2\text{N}_2\text{O}_7$ .  $[220^\circ]$ . Needles.

Propylene- $\psi$ -selenourea  $\text{C}_3\text{H}_6\text{N}_2\text{Se}$ . Obtained in like manner from  $\beta$ -bromo-propyl-amine.— $\text{B}'_2\text{C}_2\text{H}_2\text{N}_2\text{O}_7$ .  $[110^\circ]$ .— $\text{B}'_2\text{H}_2\text{PtCl}_6$ . Light-yellow plates.

Trimethylene- $\psi$ -selenourea  $\text{C}_4\text{H}_8\text{N}_2\text{Se}$ . Formed from  $\gamma$ -bromo-propyl-amine and  $\text{KSeCy}$ .— $\text{B'HBr}$ .  $[135^\circ]$ . White crystals (from alcohol) soon turning red.— $\text{B}'_2\text{C}_2\text{H}_2\text{N}_2\text{O}_7$ .  $[c. 53^\circ]$ . Small concentric needles.

Seleno-isovaleric aldehyde  $\text{C}_4\text{H}_{10}\text{Se}$ .  $[57^\circ]$ . Crystalline (Schröder, B. 4, 402).

Di-methyl-selenophene  $\text{Se} < \begin{smallmatrix} \text{CMe:CH} \\ \text{CMC:CH} \end{smallmatrix}$

**Selenoxene.** ( $154^\circ$  uncor.). Formed by heating acetyl-acetone with phosphorus pentaselenide  $\text{P}_2\text{Se}_5$  at  $180^\circ$ . Colourless mobile liquid of slight smell. With isatin and conc.  $\text{H}_2\text{SO}_4$  it gives a carmine-red colouration. By Laubheimer's reaction a reddish-brown colour is produced. Benzoyl-formic acid also produces a reddish-brown colouration (Paal, B. 18, 2255).

**SELENIUS ACID**  $\text{H}_2\text{SeO}_4$ . Mol. w. not determined. This compound is the acid of the anhydride  $\text{SeO}_3$ .

**Preparation.**—Se is dissolved in hot conc.  $\text{HNO}_3$  Aq, the solution is evaporated to dryness, the residue is dissolved in water,  $\text{BaO}$  Aq is added to ppt. traces of  $\text{H}_2\text{SeO}_3$ , the filtrate is evaporated to dryness in a retort, and the residue is heated till  $\text{SeO}_2$  sublimes (Thomsen, B. 2, 598); the pure  $\text{SeO}_2$  thus obtained is dissolved in c.  $\frac{1}{2}$  its weight of hot water, on cooling large crystals of  $\text{H}_2\text{SeO}_4$  separate (Weber, P. 118, 479). To prevent formation of  $\text{H}_2\text{SeO}_3$  in the oxidation of Se, Divers a. Shimodzu (C. J. 47, 439) recommend to dissolve Se in a large excess of conc.  $\text{H}_2\text{SO}_4$  instead of using  $\text{HNO}_3$ .

**Properties.**—Large white crystals, resembling nitre; effloresces in air; withdraws water from moist air; S.G. 3.0066 at  $15.7^\circ$  (Clausnizer, B. 11, 2009). Poisonous. The acid crystallises unchanged from solution in aqueous acetic acid, or in aqueous  $\text{C}_2\text{H}_5$  (Chabré, A. Ch. [6] 20, 202). H.F.  $[\text{SeO}_4\text{Aq}] = 50,160$  (Th. 2, 274).  $\text{H}_2\text{SeO}_4$  is a dibasic acid; this is shown by the existence of two salts  $\text{M'HSeO}_4$  and  $\text{M}'_2\text{SeO}_4$  (v. SELENITES), and also by the heat of neutralisation, which is given by Thomsen (Th. 1, 172) as follows:

$[\text{H}'\text{SeO}_4\text{Aq}, \text{NaOHAq}] = 14,770$ ,  $[\text{H}'\text{SeO}_4\text{Aq}, 2\text{NaOHAq}] = 27,020$ ,  $[\text{H}'\text{SeO}_4\text{Aq}, 4\text{NaOHAq}] = 27,480$ . As no derivative of  $\text{H}_2\text{SeO}_4$  exists corresponding with  $\text{C}_2\text{H}_5\text{SO}_3\text{OH}$ , and as only one ethyl selenite  $\text{SeO}(\text{OEt})_2$  can be obtained, and as the compound  $\text{SeO.CLOEt}$  has been isolated, it appears that the acid is  $\text{SeO}(\text{OH})_2$ , and not  $\text{SeO}_2\text{OH.H}$  (Michaelis a. Landmann, B. 13, 656; A. 241, 150).

**Reactions.**—1. Heat causes  $\text{H}_2\text{SeO}_4$  to decompose to  $\text{SeO}_2$  and  $\text{H}_2\text{O}$ .—2. Many *oxidisable bodies* remove O from  $\text{H}_2\text{SeO}_4$ . For instance, sulphur dioxide passed into  $\text{H}_2\text{SeO}_4$  Aq ppts. Se; the reduction is complete only when the compounds interact in the ratio  $\text{H}_2\text{SeO}_4:2\text{SO}_2$  (Schulze, J. pr. [2] 32, 390); the presence of HCl hastens the reaction (v. Michaelis, J. Z. 6, 88; Rathke, A. 152, 194). When  $\text{SO}_2$  and  $\text{H}_2\text{SeO}_4$  interact in other proportions than  $\text{H}_2\text{SeO}_4:2\text{SO}_2$ , thioselenic acids are formed (cf. p. 435). *Hydrogen sulphide* ppts. Se and S in the ratio  $\text{Se}:2\text{S}$  (Divers a. Shimidzu, C. J. 47, 441). Various *metals*, such as Cu, Fe, Ag, or Zn, also reduce  $\text{H}_2\text{SeO}_4$  Aq in presence of HCl, with pptn. of Se.  $\text{H}_2\text{SeO}_4$  Aq is partly reduced by exposure to air containing dust. M. M. P. M.

**SELENITES.** Salts of selenious acid ( $\text{H}_2\text{SeO}_3$ ),  $\text{M}'_2\text{SeO}_3$ , and  $\text{M}'\text{HSeO}_3$ . The alkali salts are formed by adding alkalis to  $\text{H}_2\text{SeO}_4$  Aq and evaporating; most of the other selenites are formed from the alkali salts by double decomposition.

Selenites give selenides, or metallic oxide and Se, when heated with charcoal. Heated with  $\text{NH}_4\text{Cl}$  out of air, they give a sublimate of Se. Most selenites, except those of the alkalis, are insol. in water.

Many selenites combine with  $\text{SeO}_2$  to form acid salts; many basic selenites are also known.

Boulzourenco (Bl. [2] 48, 209) found that many selenites can be obtained in well-formed crystals by adding  $\text{Na}_2\text{SeO}_3$  Aq to solutions of metallic salts, and heating the pp. so formed with very dilute  $\text{H}_2\text{SeO}_4$  Aq in sealed tubes at  $200^\circ$ ; also by dissolving metallic carbonates in dilute  $\text{H}_2\text{SeO}_4$  Aq, adding water, and heating in sealed tubes at  $200^\circ$ . The older investigations of selenites were by Berzelius (v. *Lehrbuch*) and Muspratt (C. J. 2, 52). Boulzourenco (l.c.; also A. Ch. [6] 18, 289) has made a more thorough investigation of these salts. Nilson (Bl. [2] 21, 253; 23, 260, 353, 494) has also prepared and described many selenites.

It has been thought sufficient to give the names of the metals selenites of which have been analysed. Abstracts of B.'s papers will be found in C. J. 54, 220; 60, 262; and an abstract of Nilson's paper will be found in the 3rd Supp. of the first edition of this Dictionary, p. 1786.—Al, Am, Sb, Ba, Be, Bi, Cd, Ca, Ce, Cr, Co, Cu, Di, In, Fe, La, Pb, Li, Mg, Mn, Hg (cf. Cameron a. Davy, Trans. I. 28, 146), Ni, K, Ag, Na, Sr, Th, U, Zn. M. M. P. M.

**SELENOSAMIC ACIDS, SALTS OF.** Selenosamic acid  $SeO(NH_2)OH$  has not been isolated, but the  $NH_4$  salt of this acid, and also the  $NH_4$  salt of diselenosamic acid,  $2SeO(NH_2)(OH)_2$ , have been obtained.

**Ammonium selenosamate**  $SeO(NH_2)ONH_4$  is formed by the action of dry  $NH_3$  on  $SeO_2$  dissolved in alcohol. It is a white, crystalline, deliquescent salt; very unstable, easily giving off  $NH_3$  and forming diselenosamate. Water partially converts this salt into  $(NH_4)_2SeO_3$ .

**Ammonium diselenosamate**  $2SeO(NH_2)OH.ONH_4$  is formed by boiling an alcoholic solution of the selenosamate, or by letting the solution stand over  $H_2SO_4$  in vacuo. It crystallises from alcohol in large, deliquescent prisms (v. Cameron & Macallan, *Fr.* 44, 112).

**SENNITE** is identical with **PINITE**, the methyl ether of dextrorotatory inositol.

**SEPTYL.** A name for **HEPTYL**.

**SEQUOIENE**  $C_{15}H_{24}$ , [105°]. (290°–300°). V.D. 5.66 (obs.). Occurs, together with  $C_{15}H_{24}$  (155°), S.G. 1.852,  $[a]_D^{20} = 24^\circ$ , and oily  $C_{15}H_{20}O_3$  (229°), in the leaves of *Sequoia gigantea* (Lungo & Steinkauler, *B.* 13, 1656). White plates with characteristic smell, volatile with steam; sol. alcohol, ether, benzene, and chloroform.

**SERICIC ACID**  $C_{15}H_{20}N_2O_8$ . Formed by the action of conc. baryta-water on silk (Champion, *C. R.* 72, 330). Deliquescent, translucent mass. — $BaA'$ , — $PbA'$ ; pp.

**SERIN**  $C_2H_5NO_2$ .  $\alpha$ -Amido-hydracrylic acid? S. 8 at 10°; 5 at 20°. Formed by boiling silk with dilute  $H_2SO_4$  (Crämer, *J. pr.* 96, 76; Baumann, *B.* 15, 1735; Melikoff, *C. C.* 1881, 354). Monoclinic crystals, insol. alcohol and ether. Converted by nitrous acid into glyceric acid. — $CuA'$ , — $HA'HCl$ : needles, v. e. sol. water. — $HA'HNO_2$ : minute needles.

**SERINE** v. PROTEIDS.

**SERUM ALBUMEN** v. PROTEIDS.

**SERUM CASEIN** v. PROTEIDS.

**SERUM GLOBULIN** v. PROTEIDS.

**SESAME OIL.** S.G. 919.  $\mu_D = 1.474$  at 20° (Long, *Am.* 10, 392). A fatty oil obtained from the seeds of *Sesamum orientale*. It contains glycerides of oleic and linoleic acids (Pohl, *J. pr.* 63, 400; Hazura & Grüssner, *M.* 10, 247). Gives a raspberry-red colour on warming with  $HClAq$  and cane-sugar (Zipperer, *Chem.*

*Zeit.* 11, 1600). The oil contains .05 p.c. of sesamin  $C_{18}H_{30}O_2$  [118]. S. (alcohol) .27 at 20°; 8.07 at 78°. S.G. 1.306.  $H_2SO_4$  containing  $HNO_3$  colours sesamin green and afterwards bright red (Tocher, *Ph.* [3] 23, 700).

**SEXTYL.** Another name for **HEXYL**.

**SHEA BUTTER**, obtained in West Africa from the nuts of *Bassia Parkii*, contains olein and stearin (Oudemans, *J. pr.* 89, 205).

**SHELLAC** v. LAC.

**SHIKIMIC ACID**  $C_7H_{10}O_5$ , i.e.

$CH(OH) \begin{matrix} \diagup CH(OH).CH \\ \diagdown CH_2.CH(OH) \end{matrix} CO_2H$ . [184°]. S.G.

1.599.  $\mu_D = 1.303$  at 14°.  $[a]_D = -186^\circ$  in a 7 p.c. solution. S. (ether) .015 at 23°; S. (alcohol) 2.25. Occurs in the fruit of *Illicium religiosum* (Japanese, shikimi) and Chinese star-anise (Eykmann, *R. T. C.* 4, 49; 5, 299; *B.* 24, 1278). Crystalline powder composed of minute needles, sl. sol. alcohol and  $CHCl_3$ , nearly insol. ether. Lmvorotatory. Yields p-oxy-benzoic acid when heated with  $HClAq$ . — $NH_4A'$ : crystals.

*Dihydride*

$CH(OH) \begin{matrix} \diagup CH(OH).CH \\ \diagdown CH_2.CH(OH) \end{matrix} CH.CO_2H$ . [175°].

S.G. 1.47.  $\mu_D = 1.324$  at 19°.  $[a]_D = -18^\circ$ . S. 14 in the cold. Formed by reducing the acid with sodium-amalgam in presence of  $HClAq$ . Monoclinic crystals. Converted by  $HCl$  into benzoic acid.

*Dibromide*

$CH(OH) \begin{matrix} \diagup CH(OH).CHBr \\ \diagdown CH_2.CH(OH) \end{matrix} CBr.CO_2H$ . [c. 188°]

$\mu_D = 1.295$ .  $[a]_D = -58^\circ$ . Formed by adding  $Br$  to a cold solution of the acid. Tetrahedra. Converted by moist  $Ag_2O$  into  $C_7H_7BrO_3$  [235°], S. 6.3 at 17°.  $[a]_D = +22^\circ$ , crystallising in hexagonal needles, sl. sol. ether, converted by baryta into oxyshikimic acid [156°].

**SHIKIMIPICRIN**  $C_7H_{10}O_5$  (?). [200°]. S. 6.2 in the cold. Occurs in the fruit of *Illicium religiosum* (Eykmann, *R. T. C.* 4, 53). Large crystals, m. sol. alcohol, sl. sol. ether.

**SHIKIMOLE** v. SAPPOROL.

**SIEGBURGITE.** A fossil resin found near Siegburg. It contains styracin, metastyrene, and some free cinnamic acid (Klinger & Pitschke, *B.* 17, 2742).

**SIKIMINE.** [175°]. A poisonous substance in the seeds of *Illicium religiosum* (Eykmann, *Ph.* [3] 11, 1046). Prisms, sl. sol. water, ether, and  $CHCl_3$ , v. sol. alcohol and  $HOAc$ .

**SILICA**  $SiO_2$ . (*Silicon dioxide. Silicic anhydride.*) Mol. w. not known. S.G. quartz 2.647 to 2.652, tridymite 2.282 to 2.326, amorphous 2.20 at 15.6° (Schaffgotsch, *P.* 68, 147). S.H. quartz 1737 at ord. temp., .305 at c. 400°, constant from 400° to over 1000° (Pionchon, *C. R.* 106, 1344). H.F.  $[SiO_2] = 219,240$  from amorphous Si; 211,120 from crystalline Si (Troost & Hautefeuille, *C. R.* 70, 252).

**Occurrence.**—Compounds of  $SiO_2$  are very widely distributed in large quantities; quartz, flint, chalcedony, jasper, opal, &c., are nearly pure  $SiO_2$ . Silica is the chief constituent of sandstones, felspar, agate, and a vast number of other minerals contain silica. Silica (or silicates) is also found in many plants.

**Preparation.**—(i) Amorphous silica.—1. Quartz is finely powdered, best by heating to

redness and plunging into cold water, and heated with c. 6 times its weight of  $\text{Na}_2\text{CO}_3$  in a Pt crucible till the whole fuses quietly; the cold mass is treated with water, the solution, when clear, is poured slowly into excess of fairly conc.  $\text{HClAq}$ , the liquid (after filtration, if necessary) is evaporated to dryness in a Pt dish, the residue is moistened with conc.  $\text{HClAq}$ , warmed, and allowed to stand for an hour or two; this treatment with acid is repeated two or three times; water is then added and, after warming and standing, the solution is filtered off, the residual  $\text{SiO}_2$  is washed with hot water, dried, and heated to redness.—2.  $\text{SiF}_4$  (v. p. 459) is passed into water, the gelatinous  $\text{SiO}_2$  which is pptd. is pressed between linen, thoroughly washed, dried, and heated to redness.

(ii.) Crystalline silica.—1. Moist ppt.  $\text{SiO}_2$ —e.g. the ppt. got by passing  $\text{SiF}_4$  into water—is dissolved in boiling  $\text{NaOH Aq}$ , and the solution is heated in a sealed tube; crystals of *tridymite* (v. *infra*, Properties) separate below  $180^\circ$ , and crystals of *quartz* separate above  $180^\circ$  (Maschke, *P.* 145, 549).—2. Small tubes of hard glass are half-filled with solutions of dialysed silicic acid (v. SILICA, HYDRATES OF, *infra*) containing c. 10 p.c.  $\text{SiO}_2$ , closed by fusion, and heated to  $250^\circ$  for some months; small crystals of *quartz* are thus obtained (Kroustchoff, *C. R.* 104, 602).—3. Any hydrate of  $\text{SiO}_2$  yields crystalline silica by heating in a forgo-fire (Freymy, *A. Ch.* [3] 39, 327).—4. Crystalline  $\text{SiO}_2$  is formed by fusing silicates with microcosmic salt (G. Rose, *J. pr.* 101, 228), or with borax (G. Rose, *B.* 2, 388). For other methods of preparing crystalline silica v. Rammelsberg (*B.* 5, 1006), Hautefeuille (*C. R.* 86, 1133; 90, 830), Sénarmont (*A. Ch.* 42, 129), Friedel a. Surasin (*Bl.* [2] 31, 481), and Daubrée (*Ann. M.* [5] 12, 297).

Properties.—The mol. w. of silica is unknown, but there is reason to think it is a considerable multiple of that indicated by the formula  $\text{SiO}_2$ . By applying the cryoscopic method to an aqueous solution of colloidal silicic acid (v. METASILICIC ACID, *infra*) Sabanéeff (*J. R.* 21, 515; Abstract in *C. J.* 58, 1215) obtained numbers pointing to silica being a very high polymeride of  $\text{SiO}_2$ . The great infusibility and non-volatility of silica, especially when this compound is compared with  $\text{CO}_2$ , make it probable that the molecular formula of silica is  $n\text{SiO}_2$ , where  $n$  has a large value (v. Mendeléeff's *Principles of Chemistry*, vol. ii. p. 93).

Crystalline silica.  $\text{SiO}_2$  crystallises as *quartz* in colourless, transparent, hexagonal, six-sided prisms having the axes-ratio 1:1:0.999 (S.G. c. 2.65), and as *tridymite* in hexagonal forms with the axes-ratio 1:1:631 (S.G. c. 2.3). Crystalline  $\text{SiO}_2$  is insol. or almost insol. in alkali solutions; it is attacked by  $\text{HFAq}$  slowly and without notable rise in temperature.

Amorphous silica is a white, loose, tasteless powder; S.G. 2.2. It dissolves in hot alkali solutions; after continued heating to a high temperature it is less sol. or nearly insol., owing to change into the crystalline form. Dissolves in  $\text{HFAq}$ , with intumescence and considerable rise of temperature.

Silica is fusible in the O-H flame to a

colourless glass; when fused it may be drawn into extremely fine threads. Cramer (*Zeit. für angewand. Chem.*) finds that quartz is volatile at a temperature whereat Pt boils (v. Abstract in *C. J.* 64, ii. 164).  $\text{SiO}_2$  is insol. in acids, except in  $\text{HFAq}$ . It is slightly volatilised in steam (v. Hffreys, *A.* 39, 255). Silica is insoluble in molten microcosmic salt ( $\text{NaNH}_2\text{HPO}_4$ ).

Reactions.—1. Fused with alkalis, alkali silicates are formed; with alkali carbonates  $\text{CO}_2$  is evolved.—2. Decomposes most solid salts by fusion with them with formation of silicates (cf. SILICATES, p. 448). According to Mills a. Meanwell (*C. J.* 39, 533)  $\text{SiO}_2$  does not react with pure  $\text{Na}_2\text{SO}_4$  or  $\text{K}_2\text{SO}_4$  even at a very high temperature.—3.  $\text{SiO}_2$  is decomposed by potassium at a red heat, forming K silicate and silicide; it is also reduced at red heat by calcium, strontium, and magnesium (Bunsen a. Matthiessen, *A.* 94, 111; Phipson, *Pr.* 13, 217; Parkinson, *C. J.* [2] 5, 128; Winkler, *B.* 23, 2642).—4. Heated with carbon and certain metals,  $\text{SiO}_2$  is reduced, with formation of silicides of the metals; Ir, Pd, Pt, and Ru react in this way (Boussingault, *C. R.* 82, 591; cf. Warren, *C. N.* 60, 5). Au and Ag reduce  $\text{SiO}_2$  only when strongly heated therewith in presence of  $\text{Na}_2\text{SiF}_6$  and Na (W., l.c.).—5. Dry  $\text{SiO}_2$  (prepared from  $\text{SiF}_4$ ) which has not been strongly heated reacts with molten metaphosphoric acid to form  $\text{SiO}_2\cdot\text{P}_2\text{O}_5$  and  $\text{SiO}_2\cdot2\text{P}_2\text{O}_5\cdot4\text{H}_2\text{O}$  (Hautefeuille a. Margottet, *C. R.* 96, 1052; 104, 56; v. SILICO-PHOSPHORIC OXIDES, p. 462).—6. Mixed with finely divided carbon and heated in hydrogen sulphide,  $\text{SiS}_4$  is formed (v. SILICON SULPHIDE, p. 462).—7. A mixture of  $\text{SiO}_2$  and carbon heated in chlorine or hydrogen chloride gives  $\text{SiCl}_4$  and CO (v. SILICON TETRACHLORIDE, p. 458); when bromine or hydrogen bromide is used,  $\text{SiBr}_4$  is formed (v. SILICON TETRABROMIDE, p. 457).—8. With hydrogen fluoride,  $\text{SiF}_4$  is obtained (v. SILICON TETRAFLUORIDE, p. 459).—9. Heated to low redness in vapour of boron trichloride,  $\text{SiCl}_4$  and  $\text{B}_2\text{O}_3$  are formed (Troost a. Hautefeuille, *A. Ch.* [5] 7, 476).

SILICA, HYDRATES OF. (Silicic acids.) The hydrates of  $\text{SiO}_2$  act as weak acids. The compositions of these hydrates are very uncertain. The silicates  $n\text{SiO}_2\cdot m\text{H}_2\text{O}$  are derivable from hydrates of  $\text{SiO}_2$ , some of which have been isolated while others are hypothetical (v. SILICATES, p. 448).

METASILICIC ACID  $\text{H}_2\text{SiO}_3 = \text{SiO}_2\cdot\text{H}_2\text{O}$ . (Silica monohydrate.) Obtained by the action of moist air on  $\text{Si}(\text{OEt})_4$ ;  $\text{Si}(\text{OEt})_4 + 3\text{H}_2\text{O} = \text{SiO}_2\cdot\text{H}_2\text{O} + 4\text{EtOH}$  (Ebelinen, *J. pr.* 37, 859). Also by dialysing a mixture of Na silicate and excess of  $\text{HClAq}$  until the liquid in the dialyser is free from chlorides, concentrating by boiling in a flask, allowing to gelatinise, and drying the jelly-like mass over  $\text{H}_2\text{SO}_4$  for two days (Graham, *T.* 1861, 183).  $\text{SiO}_2\cdot\text{H}_2\text{O}$  is described by Graham as a transparent, glassy, lustrous solid; insol. water.

ORTHO-SILICIC ACID  $\text{H}_4\text{SiO}_4 = \text{SiO}_2\cdot2\text{H}_2\text{O}$ . (Silica dihydrate.) This hydrate of  $\text{SiO}_2$  has not been isolated with certainty; it is supposed to exist in the solution obtained by dialysing a solution of K or Na silicate with excess of  $\text{HClAq}$ ; but as the compositions of the silicates of K and Na are very doubtful, the argument

based on the supposition that these silicates are ortho-salts—and, therefore, will yield ortho-acid—is not very trustworthy. Various esters of the form  $\text{Si}(\text{OX})_x$  exist where X is Me, Et, &c. The solution of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ , when  $x$  is supposed to = 2, obtained by dialysing K or Na silicate solution with excess of  $\text{HClAq}$  till the liquid in the dialyser is free from chlorides, is described by Graham (*l.c.*) as a clear liquid, which may be boiled in a flask till it contains c. 13 p.c.  $\text{SiO}_2$ , without separation of any solid. The liquid soon becomes opalescent on keeping, and after a time sets to a transparent, colourless jelly, which is insol. water, and dried over  $\text{H}_2\text{SO}_4$ , gives  $\text{SiO}_2 \cdot \text{H}_2\text{O}$  (*v.* METASILICIC ACID, p. 447). The solution of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$  is coagulated by a minute trace of an alkali or alkaline earth carbonate, also by  $\text{CO}_2$ , but not by dil.  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ ,  $\text{Aq.}$  or  $\text{H}_2\text{C}_2\text{O}_4$ ,  $\text{Aq.}$  The solution reddens litmus (*cf.* Doveri, *A.* 64, 256; Liebig, *A.* 94, 373; Karsten, *P.* 6, 357; Fuchs, *A.* 82, 119; Struckmann, *A.* 94, 341; Rose, *P.* 108, 20; Kühn, *J. pr.* 59, 1; Frey, *A. Ch.* [3] 88, 314; Maschke, *J. pr.* 68, 234).

TRISILICIC PHYDRATE  $3\text{SiO}_2 \cdot 2\text{H}_2\text{O} = \text{H}_2\text{Si}_2\text{O}_7$ . By decomposing K or Na silicate solution by  $\text{CO}_2$ , or  $\text{SiF}_4$  by  $\text{H}_2\text{O}$ , and drying the gelatinous pp. so formed *in vacuo*, Frey (*l.c.*) obtained a hydrate containing 16.2 to 16.8 p.c. water ( $3\text{SiO}_2 \cdot 2\text{H}_2\text{O}$  requires 16.67 p.c. water). Several naturally occurring silicates may be regarded as derived from this hydrate (*v.* SILICATES, *infra*).

DISILICIC MONOHYDRATE  $2\text{SiO}_2 \cdot \text{H}_2\text{O} = \text{H}_2\text{Si}_2\text{O}_5$ . The gelatinous pp. formed by decomposing  $\text{SiF}_4$  by water, after drying for six weeks in air at  $20^\circ$ – $25^\circ$ , was found by Merz (*J. pr.* 99, 1771) to contain from 13.1 to 13.5 p.c. water (the formula given requires 13.05 p.c. water).

OTHER HYDRATES. By drying the gelatinous pps. obtained by decomposing  $\text{SiF}_4$  by water, or by decomposing alkali silicate solutions by weak acids and washing (*v.* Kühn, *J. pr.* 59, 1), solids are obtained of varying and uncertain composition (*v.* Carnelley a. Walker, *C. J.* 53, 80); hydrates of fair definiteness agreeing approximately with the formulæ  $3\text{SiO}_2 \cdot \text{H}_2\text{O} = \text{H}_2\text{Si}_2\text{O}_5$ ,  $9\text{SiO}_2 \cdot 2\text{H}_2\text{O} = \text{H}_2\text{Si}_6\text{O}_{17}$ , and  $6\text{SiO}_2 \cdot \text{H}_2\text{O} = \text{H}_2\text{Si}_3\text{O}_{10}$  have been obtained (Fuchs, *A.* 82, 119; Gottlieb, *J. pr.* [2] 6, 185; Merz, *J. pr.* 99, 1771). For methods of preparing gelatinous pps. of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$  *v.* Struckmann, *A.* 94, 337; Kuhlmann, *A.* 41, 231; Liebig, *A.* 94, 374; Guyton-Morveau, *A. Ch.* [2] 31, 246; Hautefeuille a. Margottet, *C. R.* 96, 1052. Concerning the absorption of water by  $\text{SiO}_2$  *v.* van Bemmelen, *B.* 11, 2232; 13, 1466.

Thomsen (*Th.* 1, 215) has examined the thermal phenomena accompanying the interaction of  $\text{NaOHAq}$  and  $\text{SiO}_2\text{Aq}$ ; the  $\text{SiO}_2\text{Aq}$  was prepared by adding exactly an equivalent of  $\text{HCl}$  in dilute solution to Na silicate solution of known composition. He gives the following tables:—

$m$	$[\text{mNaOHAq} \cdot \text{SiO}_2\text{Aq}]$	$n$	$[\text{nNaOHAq} \cdot x\text{SiO}_2\text{Aq}]$
1	2652	1	1353
2	3241	2	2615
3	3555	3	3548
4	4316	4	4316
5	4731	5	5332
6	5230	6	6488
7	5412	7	7956

There seems to be no fixed point of neutralisation. Putting  $[\text{NaOHAq} \cdot x\text{SiO}_2\text{Aq}] = \frac{x \cdot \text{O}}{x+n}$

where O and n are constants having the values  $\text{O} = 13,410$  and  $n = 2.13$ , the calculated values agree very fairly with the observed so far as data go; if the formula is supposed to be accurate then the heat of neutralisation of  $\text{SiO}_2\text{Aq}$ , when  $\text{SiO}_2$  is taken as  $\infty$  in the reaction  $\text{NaOHAq} + \text{SiO}_2\text{Aq}$ , is = 13,410, which is about the thermal value of the interaction of an acid with one molecular weight of  $\text{NaOH}$ . The affinity of  $\text{SiO}_2\text{Aq}$  is almost nil. M. M. P. M.

SILICATES. Compounds of  $\text{SiO}_2$  with basic radicles. The basic radicles of silicates are generally oxygen-containing groups; sometimes they contain negative elements other than O. Silica, like other feebly acidic oxides, combines with bases in many proportions, forming compounds which may be represented as normal salts, and also compounds of the type of basic and acidic salts. The general composition of silicates is given by the formula  $n\text{SiO}_2 \cdot m\text{R}$ , where R = basic radicle. Most of the silicates occurring in rocks vary in composition between the limits  $\text{SiO}_2 \cdot 4\text{MO}$  and  $2\text{SiO}_2 \cdot \text{MO}$ , where M = a mono- or di-valent metal, and the limits  $\text{SiO}_2 \cdot 2\text{M}_2\text{O}$ , and  $6\text{SiO}_2 \cdot \text{M}_2\text{O}$ , where M = a trivalent metal. The metals most commonly found in these silicates are Al, K, Na, Ca, Mg, Fe, and Mn. A fair number of natural silicates contain Cl or F as part of the basic radicle. Few pure silicates occur in rocks: the siliceous minerals are generally mixtures of isomorphous silicates; hence it is not possible to deduce satisfactory formulae for naturally occurring silicates solely from the results of analyses of minerals.

Mendeléeff (*Principles of Chemistry*, 2, 111) compares the siliceous minerals to alloys. Several silicates which occur as mineral species have been formed artificially; the study of the alteration-products of natural silicates, and the comparison of silicates with carbon compounds (*v.* *e.g.* Mendeléeff, *l.c.*, note p. 111) throw light on the constitution of these bodies.

The most important memoirs on the constitution and chemical relations of the silicates are to be found in Groth's *Tabellarische Uebersicht der Mineralien nach ihren Krystallographisch-chemischen Beziehungen* (3rd ed.), pp. 89 *et seq.*, and in a series of papers by F. W. Clarke (*Am.* 10, 120; *Am. S.* [3] 38, 384; 40, 303; 43, 190), (*v.* also Clarke in *U.S. Geological Survey Bulletin*, No. 90 [1892]; also *A. C. J.* May 1893).

Groth and Clarke both look on the natural silicates as derived from a few fairly simple types. They are very stable compounds; most of them are formed at high temperatures, their number is not very great, and a few typical forms containing a small number of common metals are very widely distributed. Among the commoner silicates are  $\text{SiO}_2 \cdot 2\text{MO}$ ,  $2\text{SiO}_2 \cdot 3\text{MO}$ ,  $3\text{SiO}_2 \cdot 2\text{MO}$ , where M is very frequently an alkaline earth metal;  $3\text{SiO}_2 \cdot 2\text{R}_2\text{O}$ ,  $2\text{SiO}_2 \cdot \text{R}_2\text{O}$ ,  $6\text{SiO}_2 \cdot \text{R}_2\text{O} \cdot \text{M}_2\text{O}$ , and  $3\text{SiO}_2 \cdot \text{R}_2\text{O} \cdot 3\text{MO}$ , where R is Al or Fe, and M is K, Na, or an alkaline earth.

The consideration of the probable constitution of the typical silicates may be approached by seeking to derive these salts from the silicic

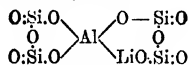

acids  $n\text{SiO}_2 \cdot m\text{H}_2\text{O}$ . *Metasilicic acid*,  $\text{SiO}_2 \cdot \text{H}_2\text{O}$ , has been isolated; the formula may be written  $\text{H}_2\text{SiO}_3$  or  $\text{OSi}(\text{OH})_2$ . *Orthosilicic acid*,  $\text{SiO}_2 \cdot 2\text{H}_2\text{O} = \text{H}_4\text{SiO}_4 = \text{Si}(\text{OH})_4$ , also probably exists. A few other hydrates of silica have been isolated, but their compositions are not quite definitely established;  $2\text{SiO}_2 \cdot \text{H}_2\text{O} = \text{H}_2\text{Si}_2\text{O}_5$ , and  $3\text{SiO}_2 \cdot 2\text{H}_2\text{O} = \text{H}_2\text{Si}_3\text{O}_7$ , seem to be fairly certain.

*Silicates derivable from metasilicic acid*  $\text{O}:\text{Si}(\text{OH})_2$ . The typical empirical formulae of normal salts of this class are  $\text{SiO}_2 \cdot \text{M}_2\text{O}$ ,  $\text{SiO}_2 \cdot \text{MO}$ ,  $3\text{SiO}_2 \cdot \text{M}_2\text{O}_3$ ,  $4\text{SiO}_2 \cdot \text{R}_2\text{O}_3 \cdot \text{M}_2\text{O}$ , and  $4\text{SiO}_2 \cdot \text{R}_2\text{O}_3 \cdot \text{MO}$ . The atomic ratio of Si to O in these salts is 1:3; this ratio is maintained in the acid salts. Silicates of the forms  $\text{SiO}_2 \cdot 2\text{MO}$  and  $\text{SiO}_2 \cdot \text{M}_2\text{O}_3$  may be represented as basic salts of this class; the atomic ratios of Si to O in these are 1:4 and 1:5. Examples of normal salts of this class are *sodium silicate*  $\text{O}:\text{Si}(\text{ONa})_2$ , *wollastonite*  $\text{O}:\text{SiO}_2\text{Ca}$ , and *leucite*  $(\text{O}:\text{SiO}_2)_3\text{Al}_2\text{K}_2$ . The basic salts may be regarded as derived from  $\text{O}:\text{Si}(\text{OH})_2$  by replacing each H by a monovalent basic radicle, such as  $\text{AlO}$  or  $\text{ZnOH}$ ; for instance, *siliceous calamine*  $\text{SiO}_2 \cdot 2\text{ZnO} \cdot \text{H}_2\text{O}$  may be formulated  $\text{O}:\text{Si}(\text{O} \cdot \text{ZnOH})_2$ , and *kyanite*  $\text{SiO}_2 \cdot \text{Al}_2\text{O}_3$  is probably  $\text{O}:\text{Si}(\text{OAl} \cdot \text{O})_2$ . If only one H is replaced in  $\text{O}:\text{Si}(\text{OH})_2$  the product will be an acid salt of the metasilicic class; *gyrolite*, for instance,  $3\text{SiO}_2 \cdot 2\text{CaO} \cdot \text{H}_2\text{O}$  may be represented as  $\text{O}:\text{Si}(\text{OH})\text{O} \cdot \text{Ca} \cdot \text{O} \cdot \text{Si} \cdot \text{O} \cdot \text{Ca} \cdot \text{O} \cdot (\text{HO})\text{Si} \cdot \text{O}$ .

*Silicates derivable from hypothetical metadisilicic acid*

typical empirical formulae of normal salts of this class are  $2\text{SiO}_2 \cdot \text{M}_2\text{O}$ ,  $2\text{SiO}_2 \cdot \text{MO}$ ,  $6\text{SiO}_2 \cdot \text{R}_2\text{O}_3$ , and  $8\text{SiO}_2 \cdot \text{R}_2\text{O}_3 \cdot \text{M}_2\text{O}$ . The atomic ratio of Si to O in these salts is 2:5; this ratio is maintained in the acid salts. Silicates of the form  $2\text{SiO}_2 \cdot 2\text{MO} \cdot \text{H}_2\text{O}$ , wherein the atomic ratio of Si to O is 2:7, may be regarded as basic salts of this class. *Petalite*  $8\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot \text{Li}_2\text{O}$  is probably an example of a normal salt of the metadisilicate class; thus

*Picrosmine*  $2\text{SiO}_2 \cdot 2\text{MgO} \cdot \text{H}_2\text{O}$  may perhaps be a basic salt of this class,

$(\text{HO} \cdot \text{Mg})\text{O} \cdot \text{Si} \cdot \text{O} \cdot \text{Si} \cdot \text{O}(\text{MgOH})$ ; but it may also be

regarded as an acid orthodisilicate (*v. infra*). One of the soluble glasses,  $4\text{SiO}_2 \cdot \text{Na}_2\text{O} \cdot \text{H}_2\text{O}$ , may be written as an acid salt of this class,  $\text{HO} \cdot \underset{\text{O}}{\text{Si}} \cdot \text{O} \cdot \underset{\text{O}}{\text{Si}} \cdot \text{ONa}$ .

*Silicates derivable from orthosilicic acid*  $\text{Si}(\text{OH})_4$ . The typical empirical formulae of normal salts of this class are  $\text{SiO}_2 \cdot 2\text{M}_2\text{O}$ ,  $\text{SiO}_2 \cdot 2\text{MO}$ ,  $3\text{SiO}_2 \cdot 2\text{M}_2\text{O}_3$ , and  $3\text{SiO}_2 \cdot \text{M}_2\text{O}_3 \cdot 3\text{M}_2\text{O}$ . The atomic ratio of Si to O in these salts is 1:4; this ratio is maintained in the acid salts. Salts of the forms  $\text{SiO}_2 \cdot 4\text{MO} \cdot 2\text{H}_2\text{O}$  and  $\text{SiO}_2 \cdot 2\text{M}_2\text{O}_3$ , atomic ratio of Si to O = 1:8, may be formulated as basic ortho-

silicates. *Olivine*  $\text{SiO}_2 \cdot 2\text{MgO}$ , and *zirconite*  $\text{SiO}_2 \cdot \text{ZrO}_2$ , are likely normal salts of this class;

$3\text{SiO}_2 \cdot 2\text{Al}_2\text{O}_3$ , is also a normal orthosilicate;

*Andalusite*  $\text{SiO}_2 \cdot \text{Al}_2\text{O}_3$  is probably partly a basic salt and partly a normal salt of this class;  $\text{Si}(\text{O} \cdot \text{Al}) \cdot \text{O} \cdot \text{AlO}$ . *Diopase*  $\text{SiO}_2 \cdot \text{CuO} \cdot \text{H}_2\text{O}$  may be formulated as an acid salt of the orthosilicate class;  $\text{Si}(\text{OH})_2 \cdot \text{O} \cdot \text{Cu}$ .

*Silicates derivable from hypothetical orthodisilicic acid*

$2\text{Si}(\text{OH})_4 - \text{H}_2\text{O} = (\text{HO})_2\text{Si} \cdot \text{O} \cdot \text{Si}(\text{OH})_3$ . The typical empirical formulae of normal salts of this class are  $2\text{SiO}_2 \cdot 3\text{M}_2\text{O}$ ,  $2\text{SiO}_2 \cdot 3\text{MO}$ ,  $2\text{SiO}_2 \cdot \text{M}_2\text{O}_3$ , and  $4\text{SiO}_2 \cdot \text{M}_2\text{O}_3 \cdot 3\text{M}_2\text{O}$ . The atomic ratio of Si to O in the normal and acid salts is 2:7. *Serpentine*  $2\text{SiO}_2 \cdot 3\text{MgO}$  is probably a normal salt of this class,  $(\text{MgO})_3 \cdot \text{Si} \cdot \text{O} \cdot \text{Si}(\text{O} \cdot \text{Mg})_2$ . *Okenite*  $\text{O} \cdot \text{Mg} \cdot \text{O}$ .

$2\text{SiO}_2 \cdot \text{CaO} \cdot 2\text{H}_2\text{O}$  seems to be an acid salt of this class,  $\text{HO} \cdot \underset{\text{O}}{\text{Si}} \cdot \text{O} \cdot \text{Si}(\text{OH})_2$ ; *picrosmine*  $\text{O} \cdot \text{Ca}$ .

$2\text{SiO}_2 \cdot 2\text{MgO} \cdot \text{H}_2\text{O}$  may also be an acid orthodisilicate,  $\text{MgO}_2 \cdot (\text{HO})\text{Si} \cdot \text{O} \cdot \text{Si}(\text{OH})_2 \cdot \text{O} \cdot \text{Mg}$ ; but it may be formulated as a basic metadisilicate (*v. supra*).

*Silicates derivable from hypothetical orthotrisilicic acid*. By removing  $2\text{H}_2\text{O}$  from  $3\text{Si}(\text{OH})_4$ , the acid  $(\text{HO})_3\text{Si} \cdot \text{O} \cdot \text{Si} \cdot \text{O} \cdot \text{Si}(\text{OH})_3$ , would remain. Some  $(\text{OH})_2$

natural silicates may be looked on as salts of this hypothetical acid; *meerschauum*, for instance,  $3\text{SiO}_2 \cdot 2\text{MgO} \cdot 2\text{H}_2\text{O}$ , may have the formula  $\text{MgO}_2 \cdot (\text{HO})\text{Si} \cdot \text{O} \cdot \text{Si} \cdot \text{O} \cdot \text{Si}(\text{OH})_2 \cdot \text{O} \cdot \text{Mg}$ . Groth (*l.c.*),

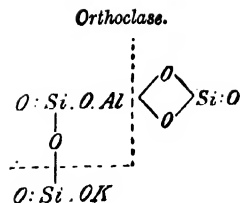

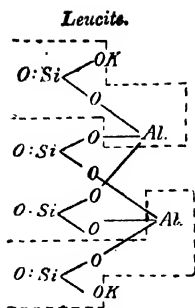

however, thinks it is not necessary to call in a hypothetical trisilicic acid to express the composition of silicates.

Some silicates which do not fit into any of the classes already mentioned may be looked on as derived from more than one of the acids simultaneously. Others may be represented as salts of hypothetical acids formed by eliminating water from one or other of the acids that have been mentioned. *Orthoclase*,  $6\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot \text{K}_2\text{O}$ , may be taken as an example of a silicate derived, according to Groth (*l.c.*), from two acids, metasilicic and metadisilicic; thus

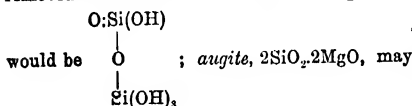

this formula is in keeping with the facts (1) that felspars of the *orthoclase* class are derived from silicates, such as *leucite*, which are metasilicates, and (2) that *orthoclase* readily yields *kaolinite*  $2\text{SiO}_2 \cdot \text{Al}_2\text{O}_3$ , which may be a basic metadisilicate. Writing *leucite* as a metasilicate, and *kaolinite* as a basic metadisilicate, it is seen that both contain the group  $\text{O}:\text{Si} \begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{O} \end{array} \text{Al}$ , a group which is represented as present in *orthoclase* also. Thus

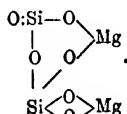

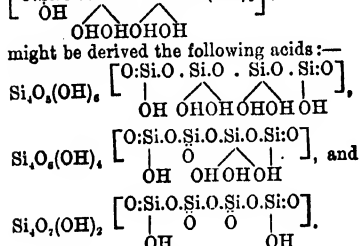

The group common to the three silicates is indicated by the dotted lines. If HHO were removed from orthodisilicic acid the product

be derived from this acid,

Again,  $4Si(OH)_4 - 3HOH = Si_4O_3(OH)_9$   
 $[(OH)_3Si.O.Si.O.Si.O.Si(OH)_3]$ ; if  $H_2O$  were  
 $(OH)_3Si(OH)_3$   
 removed from this hypothetical *orthotetrasilicic acid*, there would result  $Si_4O_3(OH)_9$   
 $[O:Si.O.Si.O.Si.O.Si(OH)_3]$ ; and from this

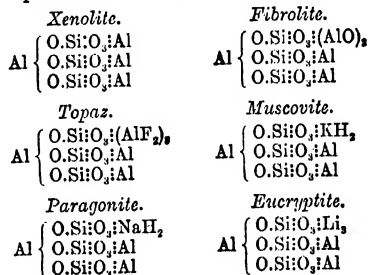

Some of the natural silicates may be represented as derived from one or other of these acids. Acids containing OH yield Cl derivatives wherein OH is replaced by Cl, generally by interaction with  $PCl_5$ . As Cl derivatives of some of the hypothetical silicic acids are known, the existence of these derivatives is an argument in favour of representing certain silicates as salts of acids which have not themselves been isolated. Thus, besides  $SiCl_4$ , which corresponds with orthosilicic acid  $Si(OH)_4$ , and  $SiCl_3SH$ , which is derived from the hypothetical orthothiosilicic acid, there exists  $Si_2OCl_4$ , corresponding with ortho-disilicic acid  $Si_2O(OH)_2$ ,  $Si_4O_3Cl_7$ , corresponding with ortho-tetrasilicic acid  $Si_4O_3(OH)_9$ ,  $Si_4O_3Cl_8$ , corresponding with the acid  $Si_4O_3(OH)_8$ , and  $Si_4O_3Cl_9$ , corresponding with the acid  $Si_4O_3(OH)_7$ , (v. *supra*).

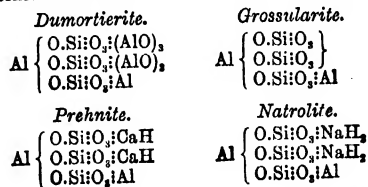

Clarke (*l.c.*), recognising the two main divisions of ortho-silicates and meta-silicates, seeks to derive the various members of each class as

far as possible from the typical normal aluminium salts by substituting metals or basic groups, wholly or partially, for Al.

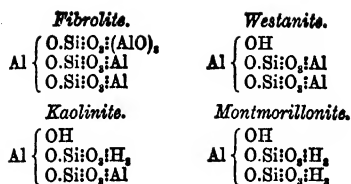

*Orthosilicates.* Clarke starts with normal Al orthosilicate,  $3SiO_2 \cdot 2Al_2O_3 = Al_2(SiO_3)_4$ , which forms the mineral species *xenolite*; allied to *xenolite* are *fibrolite*  $SiO_2 \cdot Al_2O_3 = Al_2SiO_5$ , *topaz*  $SiO_2 \cdot Al_2O_3 \cdot F_2 = Al_2SiO_5 \cdot F_2$ , *muscovite*  $6SiO_2 \cdot 3Al_2O_3 \cdot K_2O \cdot 2H_2O = 2Al_2KH_2(SiO_3)_4$ , *paragonite*, corresponding with *muscovite* but containing Na in place of K, and *eucriptite*  $2SiO_2 \cdot Al_2O_3 \cdot Li_2O = 2AlLiSiO_4$ . By trebling the formulae given for *fibrolite* and *topaz*, using the simplest formula given for *muscovite* and *paragonite*, and trebling the simplest formula given for *eucriptite*, Clarke arrives at the following comparable formulae for the six silicates:—

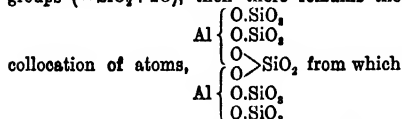

These silicates are represented as derived from normal Al orthosilicate by substituting either metals, metals and hydrogen, or basic groups, for Al. If such substitution is carried further a series of silicates may be obtained, for some of which Clarke suggests the following formulae:—

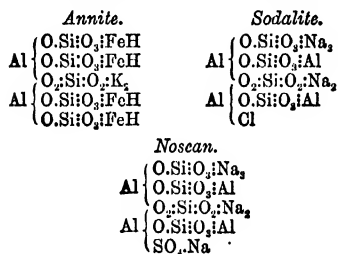

*Fibrolite* alters by hydration, giving *westanite*  $4SiO_2 \cdot 3Al_2O_3 \cdot H_2O = 2Al_2HSi_4O_{10}$ , *kaolinite*  $2SiO_2 \cdot Al_2O_3 \cdot 2H_2O = Al_2Si_2H_4O_9$ , and *montmorillonite*  $4SiO_2 \cdot Al_2O_3 \cdot 7H_2O = 2AlSi_4H_7O_{10}$ . Clarke suggests the following formulae for these products of alteration of *fibrolite*:—

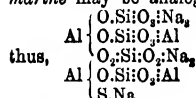

If it is supposed that two groups  $\text{Al}(\text{O.Si:O}_2)_2$ , combine with elimination of one of the  $\text{O.Si:O}_2$  groups ( $=\text{SiO}_2+2\text{O}$ ), then there remains the

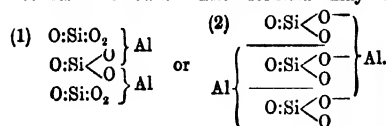

a number of silicates, especially iron and magnesian micas, may be derived. Thus—

Clarke (*Am. S.* 10, 126) suggests that *ultramarine* may be analogous to these silicates;

The metasilicates are considered by Clarke (*l.c.*) in a way similar to that whereby he has elucidated the orthosilicates. The starting-point is Al metasilicate,  $\text{Al}_2(\text{SiO}_3)_2$ . This salt is not itself known. The formula may be

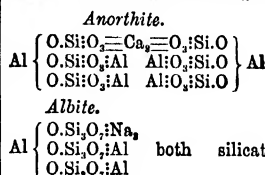

Inasmuch as many metasilicates of the form  $\text{AlM}(\text{SiO}_3)_2$ , where  $\text{M}=\text{Li, K, Na, H}$ , may be simply derived from the first, but not from the second, formula given for  $\text{Al}_2(\text{SiO}_3)_2$ , thus  $\text{O.Si:O}_2:\text{AlO.Si:O}$ , Clarke thinks that the first

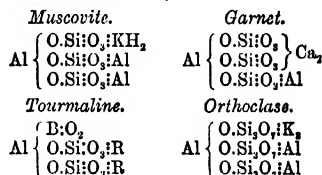

formula may be taken to represent  $\text{Al}_2(\text{SiO}_3)_2$ . Several other metasilicates may be formulated as derived from the Al salt by substituting metals or basic groups for one of the  $\text{AlSiO}_3$  groups; or many metasilicates containing divalent metals may be more simply derived from the normal form  $\text{M}^{\text{II}}\text{SiO}_3$ , by doubling this formula and then replacing one  $\text{M}^{\text{II}}$  in the formula  $\text{M}^{\text{II}}\text{M}^{\text{II}}(\text{SiO}_3)_2$  by other metals or by basic groups.

The species *albite* and *orthoclase*,  $\text{AlMSi}_3\text{O}_8$ , are looked on by Clarke as derived from the

Al salt of the acid  $\text{H}_2\text{Si}_2\text{O}_7$  ( $=8\text{SiO}_2\cdot2\text{H}_2\text{O}$ ), which acid has probably been isolated, in the same way as many orthosilicates are derived by him from the normal Al salt  $\text{Al}_2(\text{SiO}_3)_2$ . The triclinic feldspars are generally thought to consist of mixtures ranging between the limits marked by *albite*  $\text{AlNaSi}_3\text{O}_8$ , and *anorthite*  $\text{Al}_2\text{Ca}(\text{SiO}_3)_2$ ; if these formulae are trebled and written thus

sented by strictly comparable formulae. Clarke also draws attention to the fact that the four silicates *muscovite*  $6\text{SiO}_2\cdot3\text{Al}_2\text{O}_3\cdot\text{K}_2\text{O}\cdot\text{H}_2\text{O}$ , *garnet*  $3\text{SiO}_2\cdot\text{Al}_2\text{O}_3\cdot3\text{CaO}$ , *orthoclase*  $\text{AlKSi}_3\text{O}_8$ , and *tourmaline*  $4\text{SiO}_2\cdot\text{Al}_2\text{O}_3\cdot2\text{MgO}$  (or  $6\text{MgO}$ )  $\cdot\text{B}_2\text{O}_3$ , are very frequently associated in granite veins. By halving the formula for *muscovite* and writing it  $\text{Al}_2\text{KH}_2(\text{SiO}_3)_6$ , writing the formula for *garnet*  $\text{Al}_2\text{Ca}_3(\text{SiO}_3)_6$ , trebling the formula for *orthoclase* and writing it  $\text{Al}_3\text{K}_3(\text{SiO}_3)_6$ , halving the formula for *tourmaline* and writing it  $\text{AlK}_2(\text{BO}_3)(\text{SiO}_3)_2$ , where B is a metal or group equivalent to Al, very suggestive relationships are disclosed between the four silicates; thus

In *Am. S.* for November 1889 ([3] 38, 384), and *A. C. J.* May 1893, Clarke has applied the substitution method, as sketched above, to the mica group of silicates, and in the same journal for March 1892 (*Am. S.* [3] 43, 190) he has applied the same method to the *chlorite* group.

The *micas* all fall within the limits of composition indicated by the two formulae  $\text{Al}_2\text{R}'_2(\text{SiO}_3)_6$  and  $\text{AlR}'_3(\text{SiO}_3)_6$ . The first formula is derived from  $\text{Al}_2(\text{SiO}_3)_2$ , by substituting Al by one trivalent or three monovalent basic radicals; the second formula is derived from the hypothetical salt  $\text{Al}_2(\text{SiO}_3)_2$ , by substituting one, two, or three Al atoms by equivalent basic radicals. When F is present it is regarded as forming part of one or other of the monovalent groups  $\text{Mg.F}$  or  $\text{Al.F}$ . If the ratio of O to Si is greater than  $4\text{O}:\text{Si}(\text{SiO}_3)_2$  the excess of O is looked on as combined with metal to form a basic group, such as  $\text{Al.O}$ ; if the ratio of O to Si is less than  $4\text{O}:\text{Si}$  the group  $\text{Si}_2\text{O}_5$  is supposed to be present. The *micas* are all capable of being represented as isomorphous mixtures of various constituents, the compositions of which fall within the limiting formulae.

The *chlorites* are treated by Clarke (*l.c.*) similarly to the *micas*. In *Am. S.* [3] 43, 198 he gives the following general formulae which summarise the composition of the chief *micas* and *chlorites* :—

Normal orthosilicate  $\text{Al}_2(\text{SiO}_4)_3$ .*Micas.**Muscovite*  $\text{Al}_2(\text{SiO}_4)_3 \cdot \text{R}_3$ .*Normal Biotite*  $\text{Al}_2(\text{SiO}_4)_3 \cdot \text{R}_3$ .*Normal Phlogopite*  $\text{Al}_2(\text{SiO}_4)_3 \cdot \text{R}_3$ .*Clintonite*  $\text{R}^{III}_2\text{O}_2 \cdot \text{Al}_2(\text{SiO}_4)_3 \cdot \text{R}_3$ .Normal orthosilicate  $\text{Mg}_2(\text{SiO}_4)_2$ .*Chlorites.**Aphrosiderite*  $\text{Mg}_2(\text{SiO}_4)_2 \cdot \text{R}_2$ .*Orthochlorites*  $\left\{ \begin{array}{l} \text{Mg}_2(\text{SiO}_4)_2 \cdot \text{R}_2 \\ \text{Mg}(\text{SiO}_3)_2 \cdot \text{R}_2 \end{array} \right.$ .*Amesite*  $\text{O} \cdot \text{Mg}_2(\text{SiO}_4)_2 \cdot \text{R}_2$ .

**Preparation of silicates.**—Alkali silicates are formed by dissolving moist amorphous  $\text{SiO}_2$  in boiling solutions of alkalis or alkali carbonates, also by fusing  $\text{SiO}_2$  with alkalis or with alkali salts of acids which volatilise by heat. Many other silicates are obtainable by double decompositions between alkali silicates (which are sol. water) and metallic salt solutions; also by heating various metallic oxides or carbonates with  $\text{SiO}_2$ .

Some naturally occurring silicates have been prepared by the following methods:—1. *Emerald*  $\text{Be}_3\text{SiO}_{11}$ , *olivine*  $\text{Mg}_2\text{SiO}_4$ , and *enstatite*  $\text{MgSiO}_3$ , by heating  $\text{SiO}_2$  with  $\text{BeO}$  or  $\text{MgO}$  mixed with boric acid in a porcelain-oven, till the boric acid volatilised (Ebelmen, *A. Ch.* [3] 22, 211).—2. *Anorthite*  $\text{Al}_2\text{Ca}(\text{SiO}_4)_2$ , *labradorite*  $3\text{SiO}_2 \cdot \text{Al}_2\text{O}_3 \cdot \text{K}_2\text{O}$ , and *oligoclase*  $9\text{SiO}_2 \cdot 2\text{Al}_2\text{O}_3 \cdot 2\text{K}_2\text{O}$ , by strongly heating  $\text{SiO}_2$  with  $\text{K}_2\text{CO}_3$  in boric acid, or by adding  $\text{CaO}$  to molten boric acid and  $\text{SiO}_2$  at a very high temperature (E., *C. R.* 32, 710; Fouquet a. Lévy, *C. R.* 90, 620).—3. *Zirconite*  $\text{ZrSiO}_4$ , and *kyanite*  $(\text{AlO})_2\text{SiO}_3$ , by heating to redness  $\text{ZrO}_2$  in vapour of  $\text{H}_2\text{SiF}_6$ , or  $\text{SiO}_2$  in vapour of  $\text{AlF}_3$  (Deville a. Caron, *A. Ch.* [4] 5, 113; Fremy a. Feil, *C. R.* 85, 1032).—4. *Enstatite*  $\text{MgSiO}_3$ , and *leucite*  $\text{Al}_2\text{K}_2(\text{SiO}_4)_2$ , by heating  $\text{Mg}$ , or  $\text{Al}$  mixed with  $\text{KOH}$ , to low redness in  $\text{H}$  and  $\text{SiCl}_4$  vapour (St. Meunier, *C. R.* 90, 349, 1009).—5. *Orthoclase*  $\text{AlKSi}_3\text{O}_8$ , *albite*  $\text{AlNaSi}_3\text{O}_8$ , *petalite*  $\text{AlLi}_2(\text{Si}_2\text{O}_7)_2$ , by fusing a mixture of  $\text{Al}_2\text{O}_3$ ,  $\text{SiO}_2$ , and tungstate or vanadate of  $\text{K}$ ,  $\text{Na}$ , or  $\text{Li}$ ; with excess of  $\text{Al}_2\text{O}_3$ , *leucite*  $\text{Al}_2\text{K}_2(\text{SiO}_4)_2$ , is obtained (Hautefeuille, *C. R.* 90, 378, 541).—6. *Orthoclase*  $\text{AlKSi}_3\text{O}_8$ , by heating  $\text{Al}_2\text{O}_3$  and  $\text{SiO}_2$  in the ratio  $\text{Al}_2\text{O}_3:6\text{SiO}_2$ , with  $\text{KVO}_3$  (Hautefeuille a. Perrey, *C. R.* 107, 786).—7. *Phenacite*  $\text{Be}_2(\text{SiO}_4)_2$  mixed with a *lithia felspar*, quartz, and *tridymite*, was obtained by heating for fifteen days at  $600^\circ\text{--}700^\circ$  a mixture of 4.8 g.  $\text{SiO}_2$ , 1.5 g.  $\text{BeO}$ , 20 g.  $\text{LiVO}_3$ , and 1.5 g.  $\text{Li}_2\text{CO}_3$  (H. a. P., *C. R.* 106, 1800).—8. Crystals of *emerald* were prepared (H. a. P., *C. R.* 106, 1800) by heating a mixture of 12.506 g.  $\text{SiO}_2$ , 3.58 g.  $\text{Al}_2\text{O}_3$ , 2.64 g.  $\text{BeO}$ , .6 g.  $\text{Cr}_2\text{O}_3$ , and 92 g. acid  $\text{Li}$  molybdate (ratio =  $\text{Li}_2\text{O}:2:\text{MoO}_3$ ); the mixture was placed in a Pt crucible, which was heated in a muffle to low redness for twenty-four hours, when the temperature was raised to  $800^\circ$  and kept thereat for fourteen days. The product was washed with water.

**Properties and Reactions of Silicates.**—All silicates except those of the alkalis are insol. water; most of them are also insol. dil. acids. For the action of water on certain silicates when the mixtures were rapidly rotated in cylindrical

vessels v. Daubrée (*C. R.* 64, 339). Many silicates are decomposed by evaporation with  $\text{HClAq}$  or  $\text{HNO}_3\text{Aq}$ , with separation of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ , which is changed to  $\text{SiO}_2$  by heating somewhat above  $100^\circ$ . Some of those silicates which are not thus decomposed are acted on, with separation of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ , by evaporating with 8 parts conc.  $\text{H}_2\text{SO}_4$  and 3 parts water. Almost all silicates are decomposed by heating with conc.  $\text{HClAq}$  or  $\text{H}_2\text{SO}_4$ , and a little water in sealed tubes to c.  $200^\circ$ . Heating with conc.  $\text{HFAq}$ , or in  $\text{HF}$  gas, decomposes silicates with formation of  $\text{SiF}_4$ ; when a silicate is mixed with 3 parts  $\text{AmF}$  or 5 parts powdered  $\text{CaF}_2$ , and the mixture well moistened with  $\text{H}_2\text{SO}_4$ , and heated in a Pt dish, all the  $\text{Si}$  is given off as  $\text{SiF}_4$ . Fusion of a finely-powdered silicate with 4–6 parts mixed  $\text{K}_2\text{CO}_3$  and  $\text{Na}_2\text{CO}_3$  gives  $\text{K}$  and  $\text{Na}$  silicate (which is sol. water), while the metal remains as oxide. Silicates which contain  $\text{F}$  generally lose  $\text{HF}$  or silicofluoride when strongly heated; any alkali or alkaline metal, or  $\text{Fe}$  or  $\text{Al}$ , which was present in the silicate in combination with  $\text{F}$  remains as oxide (Rammelsberg, *W.* 7, 146). Clarke a. Schneider (*Am. S.* [3] 40, 303, 405, 452) have studied quantitatively the interactions of various natural silicates with  $\text{HCl}$  gas and also with  $\text{HClAq}$ ; their results make it probable that in the magnesium silicates gaseous  $\text{HCl}$  attacks only the  $\text{Mg}$  which is present as the basic monovalent radicle  $\text{Mg.OH}$ .

The following account of individual silicates does not refer to silicates which occur in rocks, but only to those salts which have been prepared in the laboratory; the chief naturally occurring silicates that have been prepared artificially are mentioned under the heading *Preparation of silicates (supra)*.

**Barium silicates.** The normal meta-salt  $\text{BaSiO}_3 \cdot x\text{H}_2\text{O}$  is formed by ppg. dil.  $\text{Na}_2\text{SiO}_3\text{Aq}$  (v. Sodium silicates, *infra*) by dil.  $\text{BaCl}_2\text{Aq}$  or  $\text{Ba}(\text{NO}_3)_2\text{Aq}$ ; not quite insol. hot water, easily sol. dil.  $\text{HClAq}$ ; retains water at  $100^\circ$  (Ammon, *J.* 1862, 138). Lefort (*J. Ph.* [3] 39, 31) says that  $\text{BaO} \cdot 3\text{SiO}_2$  3aq (?  $\text{BaH}_2\text{Si}_2\text{O}_6$  2aq) is formed by ppg. a dil.  $\text{Ba}$  salt solution by a dil. solution of  $9\text{SiO}_2 \cdot 2\text{Na}_2\text{O}$ .

**Calcium silicates.** The compounds  $3\text{SiO}_2 \cdot \text{CaO}$ ,  $2\text{SiO}_2 \cdot \text{CaO}$ ,  $3\text{SiO}_2 \cdot 2\text{CaO}$ , and  $\text{SiO}_2 \cdot 2\text{CaO}$ , are said to be produced by very strongly heating mixtures of quartz and marble in the proper proportions. By adding  $\text{CaCl}_2\text{Aq}$  to solution of  $3\text{SiO}_2 \cdot \text{K}_2\text{O}$ , a gelatinous pp. is obtained which becomes crystalline after a time; dried at  $100^\circ$ , the solid is said to be  $3\text{SiO}_2 \cdot \text{CaO} \cdot 2\text{aq}$  (?  $\text{CaH}_2\text{Si}_2\text{O}_6 \cdot \text{aq}$ ). The normal meta-salt  $\text{CaSiO}_3$  is said to be formed by ppg.  $\text{Na}_2\text{SiO}_3\text{Aq}$  by dil.  $\text{CaCl}_2\text{Aq}$  (v. A., *l.c.*; L., *l.c.*). Calcium silicates form the bases of most hydraulic cements (v. *Cements* in *DICTIONARY OF APPLIED CHEMISTRY*).

**Cerium silicate.** The normal meta-salt  $\text{Ce}(\text{SiO}_3)_2$  is said to be formed by fusing  $\text{Ce}$  oxychloride with  $\text{SiO}_2$  and  $\text{CaCl}_2$  or  $\text{NaCl}$  (Didier, *C. R.* 101, 882).

**Cobalt silicate.** The normal ortho-salt  $\text{Co}_2\text{SiO}_4$  is formed, according to Bourgeois (*C. R.* 108, 1177), by very strongly heating  $\text{CoO}$  with  $\text{CoCl}_2$  and a large excess of  $\text{SiO}_2$ .

**Nickel silicate.** Normal ortho-salt  $\text{Ni}_2\text{SiO}_4$ , formed like the  $\text{Co}$  salt (B., *l.c.*).

**Magnesium silicate.** The gelatinous pp. obtained by adding  $\text{MgCl}_2\text{Aq}$  to solution of  $8\text{SiO}_2 \cdot \text{K}_2\text{O}$  is said to be  $2\text{SiO}_2 \cdot \text{MgO} \cdot 2\text{H}_2\text{O}$  (?  $\text{MgH}_2(\text{SiO}_3)_2$ , *aq acid meta-salt*) (Heldt, *J. pr.* 94, 129, 187). The normal meta-salt  $\text{MgSiO}_3 \cdot x\text{H}_2\text{O}$  is obtained, according to Ammon (*l.c.*), by ppg.  $\text{Na}_2\text{SiO}_3\text{Aq}$  by dil.  $\text{MgCl}_2\text{Aq}$ .

**Potassium silicates.** The normal meta-salt  $\text{K}_2\text{SiO}_3$  is prepared by fusing 1 part  $\text{SiO}_2$  with  $2\frac{1}{2}$  parts dry  $\text{K}_2\text{CO}_3$ . If this product is dissolved in a little water, and alcohol is added, a gelatinous pp. is formed, which, if slightly washed and squeezed, is said to be  $4\text{SiO}_2 \cdot \text{K}_2\text{O}$ ; but Fremy (*J.* 1856, 353) gives the composition  $9\text{SiO}_2 \cdot 2\text{K}_2\text{O}$  *aq* to this pp., and this is confirmed by Lefort (*J.* 1861, 205).

The name *potash water-glass* is given to the mixture of K silicates obtained by fusing together quartz and pearlsh in a proportion about equal to  $4\text{SiO}_2 \cdot \text{K}_2\text{O}$ . Water-glass is a clear transparent solid, like glass; it is completely sol. hot water; a conc. solution, with c. 28 p.c. silicate, is syrupy, somewhat turbid, and has S.G. 1.25. The solution is decomposed by acids, even by  $\text{CO}_2$ , with separation of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ ; alkaline carbonates and chlorides, especially  $\text{AmCl}$ , ppt.  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ ;  $\text{BaO}$ ,  $\text{SrO}$ ,  $\text{CaO}$ ,  $\text{Al}_2\text{O}_3$ , and  $\text{PbO}$  decompose the solution, forming a double silicate with the whole of the silica and a portion of the K. The solution yields pps. with solutions of most of the salts of earth metals and heavy metals. Water-glass is also formed by boiling  $\text{SiO}_2$  with  $\text{KOH Aq}$  under pressure.

**Sodium silicates.** The normal meta-salt  $\text{Na}_2\text{SiO}_3$  is prepared by fusing 1 part  $\text{SiO}_2$  with  $1\frac{1}{2}$  parts dry  $\text{Na}_2\text{CO}_3$ . The salt is obtained with  $8\text{H}_2\text{O}$ , in monoclinic crystals, by dissolving  $\text{SiO}_2$  in an equivalent quantity of  $\text{NaOH}$  in solution, decanting, evaporating, as much as possible out of contact with air, till  $\text{Na}_2\text{CO}_3$  begins to settle out, cooling to  $-22^\circ$ , stirring till the whole solidifies, straining from mother-liquor, dissolving in a little water, and allowing to stand (Ammon, *J.* 1862, 138; cf. Ordway, *Am. S.* [2] 40, 186). By adding freshly ppt.  $\text{AlO}_2\text{H}_3$  to a boiling solution of  $\text{Na}_2\text{SiO}_3$  and  $\text{NaOH}$ , the double salt  $\text{Na}_2\text{SiO}_3 \cdot \text{Al}(\text{SiO}_3)_2$  is obtained; and the salt  $\text{Na}_2\text{SiO}_3 \cdot \text{Al}(\text{SiO}_3)_3$  is ppt. by adding  $\text{Na}_2\text{SiO}_3\text{Aq}$  to a hot solution of alum (*A.*, *l.c.*). Mixtures of Na silicates are known as *soda water-glass* (cf. *supra*, *Polash water-glass*). For effect of time on composition of solutions of Na silicates v. Kohlrausch (*Z. P. C.* 12, 773).

**Strontium silicate.** The normal meta-salt  $\text{SrSiO}_3$  is said to be formed by adding  $\text{Na}_2\text{SiO}_3\text{Aq}$  to dil.  $\text{SrCl}_2\text{Aq}$  (Ammon, *l.c.*).

**Thorium silicates.** The normal ortho-salt  $\text{ThSiO}_4$  and the normal meta-salt  $\text{Th}(\text{SiO}_3)_2$  are formed, according to Troost & Ouvrard (*C. R.* 105, 229), by fusing  $\text{ThO}_2$  with  $\text{SiO}_2$  and  $\text{CaCl}_2$  and treating with dil.  $\text{HCl Aq}$ .  $\text{ThSiO}_4$  is not isomorphous with  $\text{ZrSiO}_4$  (*T. a. O.*, *l.c.*).

**Zinc silicates.** The normal meta-salt  $\text{ZnSiO}_3$  is obtained in rhombic crystals by ppg.  $\text{ZnSO}_4\text{Aq}$  by  $\text{Na}_2\text{SiO}_3\text{Aq}$  and strongly heating the dried pp. with boric acid for several days (H. Traube, *B.* 26, 2735).

A systematic arrangement of the naturally occurring silicates will be found in Groth's *Tabell. Uebersichte*, pp. 108-151 [3rd ed.].

M. M. P. M.

**SILICIC ACIDS v. SILICA, HYDRATES OF, p. 447).**

**SILICIDES.** Binary compounds of Si with metals. These compounds are formed (1) by heating amorphous Si with metallic chlorides in presence of such a reducer as Na; (2) by heating  $\text{K}_2\text{SiF}_6$  with metals; (3) by electrolysis a mixture of an alkali fluoride with a metallic oxide; (4) by heating metals with Si (v. ALUMINIUM, CERIUM, COPPER, IRON, MAGNESIUM, MANGANESE, NICKEL, PLATINUM, SILICIDES OF). M. M. P. M.

**SILICO-BORATES.** Certain minerals consist of compounds of silicates and borates; the name silico-borate is sometimes applied to such

compounds.  $\begin{array}{c} \text{O:SiO} \\ \text{O} \\ \text{O:SiO} \end{array} \text{Ca} \cdot \text{CaB}_2\text{O}_7 \cdot \text{aq.}$

and *botryolite*, the same formula with 2aq, are examples of borosilicates. *Tourmalines*  $\text{Al}(\text{BO}_3)(\text{SiO}_3)_2\text{R}$ , are also silico-borates ( $\text{R}^1$  may be replaced by its equivalent of  $\text{R}^{11}$ ).

M. M. P. M.

**SILICO-BROMOFORM**  $\text{SiHBr}_3$ . (*Silicon hydrogen bromide. Tribromo-silico-methane.*) Obtained, not quite pure, by Baff and Wöhler (*A.* 104, 99) by leading  $\text{HBr}$  gas over heated Si, distilling the product, shaking with Hg, and distilling again. Gattermann (*B.* 22, 193) obtained pure  $\text{SiHBr}_3$  as follows. Crude Mg silicide, prepared as described under **SILICON**, *Preparation*, No. 1 (p. 456), is freed from  $\text{MgO}$  by powdering, adding little by little to  $\text{HCl Aq}$  (1:2), shaking with this acid for some hours, washing till the wash-water is neutral, and drying thoroughly. The Si thus obtained is heated in a tube in a stream of  $\text{HBr}$ , the tube being connected with a well-cooled receiver; the details and precautions described under **SILICON TETRACHLORIDE**, *Preparation*, No. 2 (p. 458) must be observed. The  $\text{HBr}$  required may be made by the action of  $\text{H}_2\text{SO}_4\text{Aq}$  on  $\text{KBr}$ ; G. used a cold mixture of 45 c.c. conc.  $\text{H}_2\text{SO}_4$  and 15 c.c. water, and let this drop on to 75 g.  $\text{KBr}$ ; he dried the gas by  $\text{H}_2\text{SO}_4$ . The liquid is distilled, and then fractionated till a portion boils at  $115^\circ-117^\circ$ ; most of the remainder boils at c.  $153^\circ$  and is  $\text{SiBr}_4$ . A colourless liquid, boiling  $115^\circ-117^\circ$ ; S.G. 2.7 at ordinary temperature (G., *l.c.*). Fumes much in air, and takes fire, probably because the heat produced in the decomposition of a portion by the moisture of the air suffices to start rapid oxidation (G., *l.c.*). Ice-cold water forms *silico-formic anhydride* (J. v., p. 455). Combines with  $\text{PH}_3$ , when compressed, to form a solid, unstable compound (Besson, *C. R.* 112, 530).

M. M. P. M.

**SILICO-CHLOROFORM**  $\text{SiHCl}_3$ . (*Silicon hydrogen chloride. Trichloro-silico-methane.*) Mol. w. 135.41. V.D. 67.

**Formation.**—1. Dry  $\text{HCl}$  gas is passed over Si heated below redness; the product is condensed in a flask in a freezing mixture and fractionated (Friedel & Jadenburg, *A.* 143, 118; cf. Buff & Wöhler, *A.* 104, 94).—2. Dry  $\text{HCl}$  gas is passed over siliceous pig-iron containing 15 p.c. Si (Warren, *C. N.* 60, 158).

**Preparation.**—Si, prepared by reducing sand by Mg (v. **SILICON**, *Preparation*, No. 1, p. 456) and removing  $\text{MgO}$  as described under **SILICO-BROMOFORM** (*supra*), is carefully heated in a

stream of dry HCl gas in a tube connected with a receiver surrounded by a very good freezing mixture. The directions given for preparing SiCl<sub>4</sub> must be carefully followed (v. SILICON TETRACHLORIDE, Preparation, No. 2). [Gattermann recommends to make the HCl in a Kipp's generator, using conc. H<sub>2</sub>SO<sub>4</sub> and fused NH<sub>4</sub>Cl.] The liquid in the receiver is fractionated from a flask with a side tube 75 cms. long; if this is done, no condenser is required; the flask must be warmed by water at 90°, if a naked flame is used explosions of part of the SiHCl<sub>3</sub> may result (Gattermann, B. 22, 190).

**Properties and Reactions.**—A colourless, mobile liquid, with a very disagreeable smell; boils at 35°–39° (F. a. L., l.c.). Non-conductor of electricity.

The vapour takes fire very easily in air, e.g. by bringing a hot glass rod to the mouth of a vessel in which a little SiHCl<sub>3</sub> has been shaken. Mixture of the vapour with air is explosive. Decomposed to Si and HCl by passing through a narrow tube heated to redness. Water at 0° forms Si<sub>2</sub>O<sub>2</sub>H<sub>2</sub> (v. SILICOFORMIC ANHYDRIDE, p. 455) and HCl; at the ordinary temperature SiO<sub>2</sub>·xH<sub>2</sub>O, HClAq, and H<sub>2</sub> are produced. Chlorine reacts at ordinary temperatures, forming SiCl<sub>4</sub> and HCl; bromine reacts similarly at 100°. Alcohol produces SiH(OEt)<sub>3</sub> (v. SILICON TETRAPHENYLIDE, Preparation, No. 1, p. 460). Combines with phosphorus hydride, under pressure, to form a solid unstable body (Besson, C. R. 112, 530).

M. M. P. M.  
**SILICO-ETHANE, PENTA-BROMO- DERIVATIVE OF, Si<sub>2</sub>HBr<sub>5</sub>.** (Disilicon hydrogen pentabromide. Pentabromo-silico-ethane.) In making SiBr<sub>4</sub> by passing SiH<sub>4</sub> into Br, Mahn (J. Z. 5, 163) obtained a solid in the form of white needles, melting at 89° and boiling (out of contact with air) at 230°, and giving numbers on analysis agreeing with the formula Si<sub>2</sub>HBr<sub>5</sub>. Takes fire when heated in air. M. M. P. M.

**SILICO-FLUORHYDRIC ACID** H<sub>2</sub>SiF<sub>6</sub>Aq. (Hydrofluosilicic acid.) Known only in aqueous solution.

**Preparation.**—SiF<sub>4</sub>, prepared by the interaction of CaF<sub>2</sub>, SiO<sub>2</sub>, and H<sub>2</sub>SO<sub>4</sub> (v. SILICON TETRAFLUORIDE, p. 459), is passed into water, the exit tube dipping beneath a little Hg in the bottom of the vessel which contains the water; the vessel is shaken frequently to break up the gelatinous silica which forms in the water; when the liquid becomes thickish from separated silica, it is filtered through linen; the silica is pressed, and more SiF<sub>4</sub> is passed into the filtrate, as before.

(1) SiF<sub>4</sub> + 3H<sub>2</sub>O + Aq = SiO<sub>2</sub>·H<sub>2</sub>O + 4HFAq;  
(2) 4HFAq + 2SiF<sub>4</sub> = 2H<sub>2</sub>SiF<sub>6</sub>Aq. The solution of H<sub>2</sub>SiF<sub>6</sub> may be evaporated in a Pt vessel till it contains c. 34 p.c. of the acid.

To prepare the acid solution on a large scale, Tessié du Mothay recommends to fuse a mixture of fluorspar, silica, and charcoal in an oven, and to lead the gas that is given off through condensers containing water; c. 68 p.c. of the F in the fluorspar is thus obtained as H<sub>2</sub>SiF<sub>6</sub> (C. C. 1868. 432).

**Properties and Reactions.**—H<sub>2</sub>SiF<sub>6</sub>Aq is a strongly-acid liquid, smelling like HClAq, and burning the skin. If kept in glass vessels it gradually withdraws alkali, lime, and iron

oxide (H. Rose, P. 80, 408). Truchot (C. R. 98, 821) gives H.F. [SiF<sub>4</sub>·2HFAq] = 17,000 (cf. Sabatier, A. Ch. [5] 22, 91). Thomsen gives [SiO<sub>2</sub>·Aq, 6HFAq] = 82,800; and the heat of neutralisation as [H<sup>+</sup>SiF<sub>6</sub>·Aq, 2NaOHAq] = 26,600 (Th. 1, 286). The following table is given by Stolba (J. pr. 90, 193):—

S.G. H <sub>2</sub> SiF <sub>6</sub> Aq	P.c. H <sub>2</sub> SiF <sub>6</sub>	S.G. H <sub>2</sub> SiF <sub>6</sub> Aq	P.c. H <sub>2</sub> SiF <sub>6</sub>
1.0040	0.5	1.1559	18
1.0080	1	1.1653	19
1.0161	2	1.1748	20
1.0242	3	1.1844	21
1.0324	4	1.1941	22
1.0407	5	1.2038	23

The S.G. for any percentage of H<sub>2</sub>SiF<sub>6</sub>, when n = number of half-per-cents., is given by the formula; S.G. =  $1 + n \cdot 004 + \frac{n(n-3)}{100000}$ .

By passing SiF<sub>4</sub> into fairly conc. HFAq until the liquid is saturated, hard, colourless, very hygroscopic crystals of the hydrate H<sub>2</sub>SiF<sub>6</sub>·2H<sub>2</sub>O separate; the crystals melt at 19°, and decompose at a higher temperature (Kessler, C. R. 90, 1285).

H<sub>2</sub>SiF<sub>6</sub>Aq acts as a dibasic acid (the heat of neutralisation confirms this), giving salts M<sup>n</sup>SiF<sub>6</sub> and M<sup>n</sup>SiF<sub>5</sub>; with excess of a strongly basic metallic oxide it forms metallic fluoride and SiO<sub>2</sub>·H<sub>2</sub>O—thus

H<sub>2</sub>SiF<sub>6</sub>Aq is decomposed by conc. H<sub>2</sub>SO<sub>4</sub>, also by HCl gas, with formation of SiF<sub>4</sub> and withdrawal of water. Boric acid separates SiO<sub>2</sub>·xH<sub>2</sub>O and forms fluoboric acid (q. v., vol. i. p. 530).

M. M. P. M.

**SILICO-FLUORIDES.** (Hydrofluosilicates.) Salts of H<sub>2</sub>SiF<sub>6</sub> (v. preceding article). These salts are formed by dissolving various metals—e.g. Fe or Zn—in H<sub>2</sub>SiF<sub>6</sub>Aq, or by neutralising the acid solution by the proper quantities of basic oxides or hydroxides; if excess of a strongly basic oxide is added to H<sub>2</sub>SiF<sub>6</sub>Aq, SiO<sub>2</sub>·H<sub>2</sub>O is separated and a fluoride is formed. Most of the silicofluorides are sol. water; the salts of Ba, K, Na, Ce, and a few elements allied thereto, are only slightly sol. water and insol. alcohol. Aqueous solutions of silicofluorides have an acid reaction to litmus. Silicofluorides are generally decomposed by heat, giving off SiF<sub>4</sub> and leaving fluorides; heated with AmCl, metallic chlorides remain (Stolba, J. pr. 101, 157). Some silicofluorides are decomposed by heating strongly with Fe or K, forming fluoride and Si. Conc. H<sub>2</sub>SO<sub>4</sub> evolves H<sub>2</sub>SiF<sub>6</sub>, when heated HF is given off; conc. HClAq and HNO<sub>3</sub>Aq react similarly, but more slowly and less completely; but H<sub>2</sub>SiF<sub>6</sub>Aq

partially decomposes most chlorides and nitrates in solution. Truchot (C. R. 98, 821, 1830) gives the heats of formation of alkali silicofluorides.

M. M. P. M.

**SILICO-FORMIC ACID.** By the action of water on (?)  $\text{SiI}_2$ , Friedel a. Ladenburg (A. 203, 247) obtained a white solid that gave off H when treated with KOH; the amount of H obtained agreed fairly well with the formula  $\text{SiH}_2\text{O}_2$ . If this formula is correct, the compound is probably the Si analogue of formic acid.

M. M. P. M.

**SILICO-FORMIC ANHYDRIDE**  $\text{H}_2\text{Si}_2\text{O}_3$   
 $\text{HSi:O}$

—  $\text{O}$  This body represents among Si compounds the hypothetical formic anhydride  $\text{HC:O}$

$\text{O}$  Prepared by slowly distilling  $\text{SiHCl}_3$  into water kept at  $0^\circ$ , filtering quickly the solid

that separates, washing with ice-cold water, drying *in vacuo* over  $\text{H}_2\text{SO}_4$  and then at  $150^\circ$ ; the  $\text{SiHCl}_3$  is distilled from a small flask and the distillation-tube is fused on to an inverted funnel which dips beneath the water;  $2\text{SiHCl}_3 + 3\text{H}_2\text{O} = 6\text{HCl} + \text{Si}_2\text{H}_2\text{O}_3$  (Friedel a. Ladenburg, A. 143, 118; cf. Buff a. Wöhler, A. 104, 101; also Gattermann, B. 12, 186). A white, amorphous, light powder; floats in water, sinks in ether; al. sol. water. Does not decompose at  $300^\circ$ , but at higher temperatures it glows and gives off H which takes fire explosively; burns when heated in O, emitting a brilliant light; burns when heated in a covered crucible, with formation of some amorphous Si. Heated in tube,  $\text{SiH}_2$  is given off and a thin layer of amorphous Si remains. Not acted on by acids, except HFAg which dissolves it with rapid evolution of H. Alkali and alkali carbonate solutions, including  $\text{NH}_4\text{Ag}$ , dissolve this compound, giving off H, and forming alkali silicates. A freshly-prepared aqueous solution of  $\text{H}_2\text{Si}_2\text{O}_3$  acts as an energetic reducer;  $\text{AuCl}_3\text{Ag}$  is reduced to Au; Pd salts probably to Pd mixed with Pd silicate;  $\text{SeO}_2\text{Ag}$ ,  $\text{SO}_2\text{Ag}$ ,  $\text{TeO}_2\text{Ag}$ , and  $\text{HgCl}_2\text{Ag}$  are reduced to Se, S, Te, and HgCl.  $\text{CrO}_2\text{Ag}$ , indigo solution, and salts of Pt and Ir are not reduced.

The substance obtained by Wöhler, by the action of light and water on the body he named *silicone* (v. SILICON, COMPOUNDS OF, WITH HYDROGEN AND OXYGEN, p. 459), and called by him *leukon* (A. 127, 268), and also the substance called by Geuther *silicium oxide* (J. pr. 95, 424), are probably identical with  $\text{Si}_2\text{H}_2\text{O}_3$ . M. M. P. M.

**SILICO-IODOFORM**  $\text{SiHI}_3$ . (*Silicon hydrogen iodide. Tri-iodo-silico-methane.*) Formula probably molecular, from analogy of  $\text{SiHCl}_3$ . Obtained in small quantities by the interaction of HI and crystalline Si at red heat (Buff a. Wöhler, A. 104, 99); better prepared by diluting the HI vapour with H; the product, which is a mixture of  $\text{SiI}_4$  and  $\text{SiHI}_3$ , is repeatedly fractionated;  $\text{SiI}_4$  boils at  $290^\circ$ ,  $\text{SiHI}_3$  at c.  $200^\circ$ . A mixture of  $\text{SiI}_4$  and  $\text{SiHI}_3$  is also obtained by heating  $\text{SiH}_4$  with I (Mahn, J. 1869, 248). A colourless, refractive liquid; S.G. 3.862 at  $0^\circ$ , 3.814 at  $20^\circ$ ; boils at c.  $200^\circ$ . Water produces  $\text{Si}_2\text{H}_2\text{O}_3$  (Friedel, A. 149, 96) (v. SILICO-FORMIC ANHYDRIDE, *supra*). M. M. P. M.

**SILICO-MOLYBDATES.** Compounds containing  $\text{SiO}_2$ ,  $\text{MoO}_3$ , and basic radicles; v. MOLYBDATES, vol. iii. p. 427.

**SILICON.** Si. (*Silicium.*) At.w. 28.3; mol. w. unknown. H.F. [Si, O] = 219,240 amorphous Si; 211,120 crystalline Si (Troost a. Hautefeuille, C. R. 70, 252). C.E. (linear at  $40^\circ$ ) .00000763 (Fizeau, C. R. 68, 1125). For other properties v. *Properties*, p. 456.

*Historical.*—The existence of a special earth in rocks that could be melted to glass-like substances was indicated by Pott in 1746. Scheele (*Opuscula*, 2, 67) and Bergmann (*Opuscula*, 2, 26) showed that this earth could not be changed into lime or alumina; Smithson in 1811 found that the earth acted like an acid; Berzelius, in 1823, isolated the element of this earth, and in 1854 Deville obtained the same element in crystalline form. The new element was shown to resemble carbon by the researches of Buff and Wöhler and of Friedel and Ladenburg. The name *silicon* was given from *acidum silicium* or *silex*.

*Occurrence.*—Si is not found uncombined; compounds of Si are very widely distributed in vast quantities; next to oxygen, Si (in combination) is the most widely distributed element. Silicates occur in very many rocks and soils and in plant-ashes;  $\text{SiO}_2$  is found in many mineral springs and in sea-water (Forchhammer, *Pr. E.* 2, 303; Bunsen, A. 62, 7, 25), and in small quantities in various animal organisms (von Gorup-Besanez, A. 61, 46; Henneberg, A. 61, 261). Si is found in pig-iron; it is generally supposed to exist therein as crystallised Si, but the experiments of Jordan a. Turner (O. J. 49, 215) make it probable that the Si is combined with Fe as a silicide.

*Formation.*—*Amorphous silicon.*—1. By passing the vapour of  $\text{SiCl}_4$  over heated K, removing excess of  $\text{SiCl}_4$  by a current of dry air, and washing out KCl with water (Berzelius, *Lehrb.* (1st ed.) 3, 327).—2. By passing vapour of  $\text{H}_2\text{SiF}_6$  over heated K, washing with water, heating the residue in a covered crucible (to remove H and O), washing with HFAg (to remove  $\text{SiO}_2$ ) and then with water (B. l.c.).—3. By heating a mixture of  $\text{K}_2\text{SiF}_6$  and K, and washing with water (B. l.c.); Wöhler (A. 104, 107) heats a mixture of  $\text{Na}_2\text{SiF}_6$  with NaCl and Na.—4. By heating Mg in  $\text{SiF}_4$  vapour (Warren, C. N. 58, 215).—5. By reducing  $\text{SiO}_2$  by heating with Mg (v. *Preparation*, No. 1).—6. By electrolysis a fused silicate in a carbon crucible, with Pt as the positive, and gas-carbon as the negative, electrode (Hampe, *Chem. Zeitung*, 12, 841). *Crystalline silicon.*—7. By heating a mixture of  $\text{K}_2\text{SiF}_6$ , Na, and Zn (v. *Preparation*, No. 2).—8. By reducing  $\text{K}_2\text{SiF}_6$  or a silicate by Al (v. *Preparation*, No. 3).—9. By passing H and  $\text{SiCl}_4$  vapour over Zn heated to redness in a porcelain tube (Beketoff, *Bl.* 1, 22).—10. By heating a mixture of  $\text{SiO}_2$ ,  $\text{K}_2\text{CO}_3$ , Iceland spar, and Na (Deville, A. Ch. [3] 49, 62).—11. By passing vapour of  $\text{SiF}_4$  or  $\text{SiCl}_4$  over Si heated to redness (Troost a. Hautefeuille, C. R. 73, 443).—12. By passing vapour of  $\text{SiCl}_4$  over heated Na, or Al, and heating the product (Si with excess of Na or Al) in a carbon crucible (Deville, A. Ch. [8] 49, 62).—13. A piece of siliceous pig-iron is connected with the positive pole of a battery and

immersed in dilute  $\text{H}_2\text{SO}_4\text{Aq}$ , in which a Pt plate connected with the negative pole of the battery is also placed; after some hours the iron has dissolved; the mixture of graphite, amorphous Si and  $\text{SiO}_2$  which remains is heated to full redness for some time with Zn and the fused mass is treated with dilute  $\text{HClAq}$  (Warren, *C. N.* 57, 54).

**Preparation.**—Amorphous silicon.—1. An intimate mixture of 10 g. Mg powder and 40 g. thoroughly dry sand is placed in a test-tube, of fairly thick glass, c. 2.3 cms. diameter and c. 15 cms. long; the tube is heated throughout by a large flame, and then the lower part is very strongly heated, when reduction quickly occurs. If the tube is gradually moved downwards so that one part is strongly heated after another, the whole of the  $\text{SiO}_2$  is reduced in a few minutes. The contents of the tube are shaken out, pulverised, and treated with  $\text{HClAq}$  (1:2), the solid being added to the acid in small successive quantities (to prevent explosion from evolution of  $\text{SiH}_4$ ) (Gattermann, *B.* 22, 186). Crystalline silicon.—2. A mixture of 15 parts dry  $\text{K}_2\text{SiF}_6$ , 20 parts dry granulated Zn, and 4 parts dry Na in small pieces is placed in a clay crucible, which is covered and heated to redness; when the reduction of the  $\text{K}_2\text{SiF}_6$  is effected (there is a visible, but not violent, reaction) the temperature is raised till the mass melts, care being taken not to heat to the b.p. of zinc, else considerable loss will occur. The crucible is broken when cold, the regulus is heated to the m.p. of zinc, the molten zinc is poured off, and  $\text{SiO}_2$ , Zn, &c., are removed by treatment, in succession, with conc.  $\text{HClAq}$ , conc. boiling  $\text{HNO}_3\text{Aq}$ , and  $\text{HFAq}$ . The Si, mixed with a little  $\text{K}_2\text{SiF}_6$ , thus obtained is placed in a crucible and covered with a layer of powdered glass; the crucible is set inside another, and heated to the m.p. of pig-iron (c.  $1100^\circ$ ). When all is melted the crucible is allowed to cool to dull redness and is then plunged into water; the regulus is separated from the slag, and is treated with  $\text{HFAq}$  and then washed with water (Caron, *A. Ch.* [3] 63, 26; Deville a. C., *A. Ch.* [3] 67, 435).—3. A mixture of 1 part Al with 20–40 parts thoroughly dry  $\text{K}_2\text{SiF}_6$  or  $\text{Na}_2\text{SiF}_6$  is heated to c.  $950^\circ$  in a Hessian crucible, and the contents are kept molten for c. a quarter of an hour; the crucible is broken when cold, the regulus is separated, crushed, heated with conc.  $\text{HClAq}$  as long as H is given off, then with  $\text{HFAq}$ , and washed with water and dried (Wöhler, *A.* 97, 261). Or, a mixture of 10 parts powdered cryolite and 5 parts  $\text{K}_2\text{SiO}_3$  or powdered glass is divided into two equal parts; one part is placed in a Hessian crucible, 1 part Al is added, the rest of the mixture is placed over this, and the whole is heated to redness for half an hour. The regulus is treated with conc.  $\text{HClAq}$ ,  $\text{HNO}_3\text{Aq}$ , &c., as directed above.

**Properties.**—Si exists as a brown amorphous powder, and also as greyish-black, very lustrous, octahedral crystals.

Amorphous silicon is a lustrous, brown powder, which adheres to the fingers or to glass tenaciously. The S.G. has not been determined, but the powder is heavier than oil of vitriol; it is a non-conductor of electricity; burns when

heated in air or O, but the  $\text{SiO}_2$  formed soon stops the process; dissolves in cold  $\text{HFAq}$ , forming  $\text{SiF}_4$  and H; also dissolves in warm alkali solutions; is oxidised with incandescence when thrown into molten nitre; combines with S when warmed therewith. After being strongly heated in a covered Pt crucible, and the  $\text{SiO}_2$  formed has been removed by  $\text{HFAq}$ , amorphous Si is a dark chocolate-brown powder, which is not burnt by heating in air or O, is insol.  $\text{HFAq}$  and boiling alkali solutions, does not combine with S, and is not acted on by molten  $\text{KNO}_3$  or  $\text{KClO}_4$ .

Crystalline silicon is obtained in leaflets or needles. The leaflets are opaque, very lustrous, metal-like, greyish black, resembling graphite; they consist of regular octahedra. The needles are also octahedral. Crystalline Si has S.G. 2.49 at  $10^\circ$  (Wöhler, *J.* 9, 437); 2.194 to 2.197 (Winkler, *J.* 17, 208). Scratches glass, but not topaz. According to Deville (*C. R.* 39, 321) crystalline Si 'conducts electricity like graphite.' M.P. between those of pig-iron and steel, i.e. between c.  $1100^\circ$  and c.  $1300^\circ$ . Crystalline Si is not changed when heated, even to whiteness, in O; it is unacted on by  $\text{HFAq}$ ; dissolves in warm alkali solutions; combines with S vapour. When heated in the electric arc crystalline Si melts and then boils, and the ends of the electrodes become covered with crystals of SiC (Moissan, *C. R.* 117, 423).

For the lines in the emission spectrum of Si v. B. *A.* 1834. 441.

Deville (*A. Ch.* [3] 49, 70) thought that a graphite-like form of Si existed different from the ordinary crystalline (or diamond-like) form; but Miller (*P. M.* [3] 31, 397) showed that both the leaflets and the needles consisted of octahedra. Kopp (*A. Suppl.* 5, 72) found differences between the specific heats of crystalline Si and the graphite-like form prepared by the interaction of  $\text{K}_2\text{SiF}_6$  and Al, and these differences were confirmed by Winkler (*J. pr.* 91, 298).

Warren (*C. N.* 63, 46) thought he had obtained a crystalline form of Si (oblique octahedra) different from the ordinary by the action of impure Al on  $\text{K}_2\text{SiF}_6$  at a very high temperature; he described the crystals as very perfect, and sometimes half-an-inch across the faces.

**Specific heat of silicon.** Kopp, Regnault, and others obtained values for the S.H. of Si varying from .188 to .173 at c.  $30^\circ$ – $100^\circ$ . In 1875 Weber (*P. M.* [4] 49, 161, 276) showed that S.H. of crystallised Si increased rapidly from  $-40^\circ$  to c.  $200^\circ$ , and attained an almost constant value at the latter temperature. Weber's results gave the following values for S.H. of crystallised Si:—

Temp.	S.H.
$-40^\circ$	.186
+ 57	.1833
128	.196
184	.2011
232	.2029

The atomic weight of Si has been determined (1) by finding the ratio of Si to  $\text{SiO}_2$  formed therefrom (Berzelius, *P.* 1, 226 [1824]); (2) by converting  $\text{BaSiF}_6$  into  $\text{BaSO}_4$  (B., *P.* 8, 20

[1829]); (3) by ppg. Cl in  $\text{SiCl}_4$  by Ag (Pelouze, *C. R.* 20, 1047 [1845]; Dumas, *A. Ch.* [3] 55, 183 [1859]); (4) by converting  $\text{SiCl}_4$  into  $\text{AgCl}$  (Schiel, *A.* 120, 94 [1861]); (5) by decomposing  $\text{SiBr}_4$  by water and determining  $\text{SiO}_2$  produced (Thorpe & Young, *C. J.* 51, 576 [1887]); (6) by finding V.D. of  $\text{SiH}_4$ ,  $\text{SiCl}_4$ ,  $\text{SiBr}_4$ ,  $\text{SiF}_4$ , &c.; (7) by determining S.H. of Si. The atom of Si is tetravalent in the gaseous molecules  $\text{SiH}_4$ ,  $\text{SiCl}_4$ ,  $\text{SiBr}_4$ ,  $\text{SiF}_4$ ,  $\text{SiHCl}_3$ , &c. The molecular weight of Si is unknown.

Si is closely related to C, and less closely to Ti, Ge, Zr, Sn, Ce, Pb, and Th (v. CARBON GROUP OF ELEMENTS, vol. i. p. 682).

**Reactions and Combinations.**—I. Amorphous silicon which has not been heated.—1. Heated in air or oxygen burns to  $\text{SiO}_2$ , which coats the Si, so that the process soon stops.—2. Heated with sulphur forms  $\text{SiS}_2$  (Berzelius).—3. In molten nitre forms potassium silicate, with incandescence.—4. Dissolves in cold solution of fluorhydric acid to form  $\text{SiF}_4$  and H.—5. Dissolves in conc. alkali solutions on warming, forming  $\text{H}_2\text{SiO}_3\text{Aq}$  (or  $\text{Na}_2\text{SiO}_3\text{Aq}$ ) and H. For differences between amorphous silicon before and after heating, v. *Properties of amorphous silicon*, p. 456.—II. Crystalline silicon.—6. Is not acted on by oxygen, nor by fluorhydric acid.—7. Heated in dry chlorine forms  $\text{SiCl}_4$ ; in bromine vapour forms  $\text{SiBr}_4$ ; in a mixture of iodine vapour and  $\text{CO}$  forms  $\text{SiI}_4$ ; takes fire in fluorine, forming  $\text{SiF}_4$  (Moissan, *C. R.* 103, 256).—8. Heated with sulphur vapour forms  $\text{SiS}_2$ .—9. Strongly heated in nitrogen forms  $\text{Si}_3\text{N}_4$ .—10. Heated to c.  $800^\circ$  in a mixture of oxygen and chlorine,  $\text{Si}_2\text{OCl}_4$  is formed (Troost & Hautefeuille, *Bl.* [2] 35, 360).—11. Dissolves slowly in warm alkali solutions of medium concentration, giving off H.—12. Burns when heated with alkali carbonates, separating C, and giving off  $\text{CO}$ .—13.  $\text{SiS}_2$  is produced (according to Sabatier, *Bl.* [2] 38, 153) by heating to bright redness in hydrogen sulphide.—14. Schutzenberger (*C. R.* 114, 1089) obtained a mixture of  $\text{Si}_3\text{N}_4$  and a carbide (to which he gives the formula  $\text{SiC}$ ) by heating to bright redness, in a carbon crucible placed inside another crucible packed with lamp-black, a mixture of 1 part Si and 2 parts  $\text{SiO}_2$ .—The following reactions apply generally to silicon.—15. Heated in hydrogen chloride  $\text{SiHCl}_3$  is formed; in hydrogen iodide mixed with H,  $\text{SiHI}_3$  is produced; and  $\text{SiHBr}_3$  is obtained by heating in hydrogen bromide.—16. Heated with silicon tetrachloride,  $\text{Si}_2\text{Cl}_6$  (and ? $\text{SiCl}_4$ ) is formed.—17. Oxidised by hydrogen iodide solution (v. Ditte, *Bl.* [2] 13, 322).—18. With molten caustic soda or potash, H is given off and a silicate formed; similar but slower reactions occur with baryta and lime (v. Berzelius, *A.* 49, 247).—19. Heated with several metallic oxides, such as  $\text{PbO}$  or  $\text{Ag}_2\text{O}$ , reduction occurs, generally with formation of a silicide. If a mixture of powdered Si, Al, and  $\text{PbO}$  is heated, a violent explosion occurs.—20. According to Colson (*Bl.* [2] 88, 56),  $\text{Si}_2\text{O}_3\text{O}$  is formed by heating Si in carbon dioxide;  $\text{SiS}$ ,  $\text{SiSO}$ , and  $\text{Si}_2\text{O}_3\text{S}$  are formed by heating Si to white heat in carbon disulphide;  $\text{SiCO}_2$  is formed by heating with benzene; and  $\text{Si}_2\text{O}_3\text{O}_2$  is produced when Si is heated to whiteness in a carbon crucible.

**Silicon, amidonitride of.** By the interaction of  $\text{NH}_3$  and  $\text{SiCl}_4$  or  $\text{SiF}_4$ , Harris (*C. C.* 1899 [ii.] 238) obtained a snow-white powder, to which he gave the formula  $\text{Si}_2\text{NH}_2\text{N}$ .

**Silicon, carbide of.** According to Schutzenberger (*C. R.* 114, 1089), a compound of Si and C, having the composition of  $\text{SiC}$ , is formed along with a little  $\text{Si}_3\text{N}_4$ , by placing a mixture of 1 part crystallised Si and 2 parts  $\text{SiO}_2$  in a covered gas-carbon crucible, imbedding this in lamp-black in a larger crucible, and this again in more lamp-black in another larger crucible, and heating to bright redness for some hours; boiling with moderately conc.  $\text{HFAq}$  dissolves  $\text{SiO}_2$  and  $\text{Si}_3\text{N}_4$ , and leaves the  $\text{SiC}$ . Heated to low redness in chlorine,  $\text{SiC}$  is said to give  $\text{SiCl}_4$ , and C. Moissan (*C. R.* 117, 425) obtained colourless crystals of  $\text{SiC}$  by fusing C and Si in an electric furnace. The crystals are very hard, act strongly on polarised light, S.G. 3.12; they are not acted on by O or S vapour at  $1000^\circ$ ; Cl begins to react at c.  $600^\circ$  and the action is complete at  $1200^\circ$ ; the crystals are not acted on by boiling  $\text{HClAq}$ ,  $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$ , *agua regia*, or a mixture of  $\text{HNO}_3$  and  $\text{HFAq}$ , nor by fused  $\text{KNO}_3$  or  $\text{KClO}_3$ ; molten  $\text{KOH}$  gradually forms  $\text{K}_2\text{CO}_3$  and K silicate.

**Silicon, bromides of.** Two bromides of Si are known,  $\text{Si}_2\text{Br}_6$  and  $\text{SiBr}_4$ .

**SILICON HEXABROMIDE  $\text{Si}_2\text{Br}_6$ .** (*Silicon tribromide  $\text{SiBr}_3$* .) Formula probably molecular from analogy of  $\text{Si}_2\text{Cl}_6$ . A colourless liquid, boiling at c.  $240^\circ$ . Formed by adding the proper quantity of Br to  $\text{Si}_2\text{I}_6$  in  $\text{CS}_2$ , pouring off from I, purifying by shaking with Hg, filtering in dry air, and fractionating (Friedel & Ladenburg, *J.* 203, 254).

**SILICON TETRABROMIDE  $\text{SiBr}_4$ .** Mol. w. probably 347.3.

**Preparation.**—Amorphous Si, prepared as described under SILICON, Preparation, No. 1 (p. 456), after being partially purified from  $\text{SiO}_2$  by  $\text{HClAq}$ , washing, and drying, is heated in a glass tube, while Br vapour is passed over it; the tube passes into a small flask, which is surrounded by cold water. A mixture of  $\text{SiBr}_4$  and Br collects in the flask; this is fractionated, and the last traces of Br are removed by shaking with Hg and distilling (Gattermann, *B.* 22, 186).  $\text{SiBr}_4$  may also be prepared by heating a mixture of  $\text{SiO}_2$  and C (cf. SILICON TETRACHLORIDE, p. 458) in Br, shaking with Hg, and fractionating (Serullas, *P.* 24, 341; modified by Reynolds, *C. J.* 51, 590).

**Properties and Reactions.**—A colourless liquid, having a disagreeable odour, and fuming much in air. S.G. 2.8128 at  $0^\circ$ . B.p.  $153.4^\circ$  at 762.5 mm. (Piorre, *A. Ch.* [3] 20, 26; Freyer & Meyer, *Zeit. für anorgan. Chemie*, 2, 1);  $148^\circ$  to  $150^\circ$  (Serullas, *l.c.*). Solidifies at c.  $-12^\circ$  (F. a. L., *l.c.*). Decomposed by water to  $\text{HBrAq}$  and  $\text{SiO}_2$ ; shaken with conc. sulphuric acid, slowly changes to Br and  $\text{SiO}_2$ . Heated to  $250^\circ$  with lead oxide gives  $\text{PbBr}_2$  and Pb silicate (Friedel & Ladenburg, *A.* 147, 362). Ammonia probably forms  $\text{SiBr}_3\text{NH}_2$  (Persoz, *A. Ch.* [2] 44, 315). Phosphorus hydride forms a white amorphous compound, by repeated compression with  $\text{SiBr}_4$ , the pressure being maintained for some hours (Besson, *C. R.* 110, 240).

For the compounds  $\text{SiBr}_3\text{H}$  and  $\text{Si}_2\text{Br}_5\text{H}$  v.

**SILICOBROMOFORM**, and **SILICO-ETHANE**, **PENTA-BROMO- DERIVATIVE** OF, pp. 453, 454.

**Silicon, bromochlorides of.** Three compounds of Si with Br and Cl have been isolated. The V.D. of  $\text{SiBr}_2\text{Cl}$ , and also that of  $\text{SiBrCl}_2$ , has been determined; the formulæ of all are probably molecular.

**SILICON BROMO-TRICHLORIDE**  $\text{SiBrCl}_2$ . Mol. w. 214.16. A colourless liquid, boiling at c.  $80^\circ$ , fuming in air, and decomposed by water. Prepared by heating Br and  $\text{SiHCl}_3$  at  $100^\circ$ ;  $\text{SiHCl}_3 + \text{Br}_2 = \text{SiBrCl}_2 + \text{HBr}$  (Friedel a. Ladenburg, *A.* 145, 187). Also by the interaction of Br and  $\text{SiCl}_4\text{SH}$  ( $? \text{SiCl}_4\text{SH} + 3\text{Br} = \text{SiBrCl}_2 + \text{SBr} + \text{HBr}$ ) (F. a. L., *l.c.* p. 179). V.D. 104.7 at c.  $130^\circ$  (F. a. L., *l.c.*). Reacts with  $\text{NH}_3$  to form an amorphous compound,  $2\text{SiBrCl}_2 \cdot 11\text{NH}_3$ , easily decomposed by water (Besson, *C. R.* 112, 788).

**SILICON DIBROMO-DICHLORIDE**  $\text{SiBr}_2\text{Cl}_2$ . A colourless liquid, boiling at  $103^\circ$ – $105^\circ$ , and not solidifying at  $-60^\circ$ . Prepared by heating  $\text{SiHCl}_3$  and Br above  $100^\circ$  (F. a. L., *l.c.*). Also by passing the vapour of HBr and  $\text{SiCl}_4$  through a red-hot porcelain tube (Besson, *l.c.*). Combines with  $\text{NH}_3$  to form  $\text{SiBr}_2\text{Cl}_2 \cdot 5\text{NH}_3$ , decomposed by water.

**SILICON TRIBROMO-CHLORIDE**  $\text{SiBr}_3\text{Cl}$ . Mol. w. 302.92. A colourless liquid, fuming in air, boiling at  $140^\circ$ – $141^\circ$ , not solidifying at  $-40^\circ$ ; S.G. 2.432. V.D. 150.5 at c.  $185^\circ$  (Reynolds, *C. J.* 51, 690). Obtained, along with  $\text{SBr}_2$ , by passing Br vapour over a mixture of  $\text{SiO}_2$  and C heated in a wind-furnace, passing dry H through the warm product, shaking with Hg, and fractionating (B., *l.c.*). Besson (*C. R.* 112, 788) seems to have obtained the same compound, along with  $\text{SiBr}_2\text{Cl}_2$ , by passing the vapours of HBr and  $\text{SiCl}_4$  through a red-hot porcelain tube. B. gives the b.p.  $126^\circ$ – $128^\circ$ , and m.p.  $-39^\circ$ ; he says a compound  $\text{SiBr}_2\text{Cl}_2 \cdot 11\text{NH}_3$  is formed by interaction with  $\text{NH}_3$ .

**Silicon, bromo-iodides of, v. SILICON IODOBROMIDES**, p. 461.

**Silicon, chlorides of.** Two chlorides of Si have been isolated with certainty,  $\text{Si}_2\text{Cl}_6$  and  $\text{SiCl}_4$ ; these formulæ are molecular. There are indications of the existence of another chloride,  $\text{SiCl}_3$ .

**SILICON HEXACHLORIDE**  $\text{Si}_2\text{Cl}_6$ . (*Silicon trichloride*  $\text{SiCl}_3$ .) Mol. w. 268.22.

**Preparation.**—1. By heating  $\text{HgCl}_2$  with  $\text{SiI}_4$ , fractionating, and distilling the portion boiling at  $146^\circ$ – $148^\circ$  from  $\text{HgCl}_2$  (Friedel a. Ladenburg, *A.* 203, 253).—2. Vapour of  $\text{SiCl}_4$  is passed over Si kept molten in a porcelain tube ( $3\text{SiCl}_4 + \text{Si} = 2\text{Si}_2\text{Cl}_6$ ); the product is rapidly cooled, and fractionated from  $\text{SiCl}_4$ , Si oxychlorides (and  $? \text{SiCl}_3$ ) (Troost a. Hautefeuille, *A. Ch.* [5] 7, 459).

**Properties.**—A colourless, mobile liquid, boiling at  $146^\circ$ – $148^\circ$ ; S.G. 1.58 at  $0^\circ$ ; solidifies at  $-14^\circ$  to large leaflets, which melt at  $1^\circ$  (F. a. L., *l.c.*). V.D. 140 at c.  $240^\circ$  (T. a. H., *l.c.*). Fumes in air, decomposed by water; vapour takes fire when  $\text{SiCl}_4$  is heated in air.

**Reactions and Combinations.**—1. Decomposed to  $\text{SiCl}_4$  and Si by heat in a closed tube; decomposition is extremely slow at  $350^\circ$ , nearly complete at  $800^\circ$ ; heated rapidly above  $1000^\circ$

the dissociation-pressure falls; the compound is stable below  $350^\circ$  and above  $1000^\circ$  (T. a. H., *l.c.*).—2. Decomposed by water. At ordinary temperatures products remain in solution, and are ppd. by  $\text{NH}_3\text{Aq}$ ; at  $0^\circ$   $\text{Si}_2\text{H}_5\text{O}_2$  is formed (v. **SILICO-OXALIC ACID**, p. 463) (F. a. L., *l.c.*).—3. *Caustic potash* forms  $\text{SiO}_2$  and gives off H (F. a. L., *A.* 203, 254).—4. *Phosphorus hydride* is changed to the solid hydride at  $-10^\circ$  (Besson, *C. R.* 110, 516).—5. Combines with ammonia to form  $\text{Si}_2\text{Cl}_6 \cdot 5\text{NH}_3$  (B., *l.c.*).

**SILICON TETRACHLORIDE**  $\text{SiCl}_4$ . Mol. w. 169.78. Boils at  $57^\circ$ – $57^\circ$  at 760 mm. pressure (Thorpe, *C. J.* 37, 327). S.G.  $1.52408$  (T., *l.c.*). V.D.  $85.5$  at  $100^\circ$  (Dumas, *A. Ch.* [2] 33, 368). S.H. of  $\text{SiCl}_4$  vapour, at  $90^\circ$  to  $234^\circ$ , = 1322, at constant pressure, referred to equal weight of water; 12, at constant volume, referred to equal weight of water (Regnault, *Acad.* 26, 1). Regnault (*l.c.*) gives the vapour-pressures of  $\text{SiCl}_4$  as follows:—

Temp.	Vapour-pressure.
$-20^\circ$	26.49 mm. mercury
$-10$	46.46 " "
$0$	78.02 " "
$+10$	125.90 " "
$20$	195.86 " "
$30$	294.49 " "
$40$	429.08 " "
$50$	607.46 " "
$60$	837.23 " "

H.F. [ $\text{SiCl}_4$ ] = 157,640 (Troost a. Hautefeuille, *A. Ch.* [5] 9, 70).

**Formation.**—1. By passing dry Cl, or HCl gas, over a mixture of  $\text{SiO}_2$  and C at full red heat (Oerstedt, *B. J.* 6, 119; Deville, *A. Ch.* [3] 43, 23). According to Weber (*P.* 112, 649) C is not necessary if the temperature is high enough. 2. By heating crystalline Si, or Si containing H, in Cl (Berzelius, *C. J.* 4, 91).—3. Favre (*C. R.* 107, 339) heats impure Si, and passes HCl and vapour of naphthalene over it.—4. By heating iron containing c. 15 p.c. Si in Cl (Warren, *C. N.* 60, 158).—5. By passing vapour of  $\text{BCl}_3$  over  $\text{SiO}_2$  heated to dull redness ( $4\text{BCl}_3 + 3\text{SiO}_2 = 3\text{SiCl}_4 + 2\text{B}_2\text{O}_3$ ; Troost a. Hautefeuille, *A. Ch.* [5] 7, 476).

**Preparation.**—1. Amorphous  $\text{SiO}_2$  is mixed with an equal weight of lampblack, and the mixture is made into a paste with oil. Small pellets are made of this paste; these are imbedded in charcoal powder, and strongly heated. The dry pellets are placed in a porcelain tube, which is heated to very bright redness in a furnace while a stream of Cl (dried by  $\text{H}_2\text{SO}_4$  and then by  $\text{CaCl}_2$ ) is passed through. The exit end of the porcelain tube is connected with a U-tube, from the bottom of the bend of which a short tube passes down into a small flask; the U-tube and small flask are surrounded by a freezing mixture. The  $\text{SiCl}_4$  which condenses in the flask is shaken in a dry flask with Hg and a few pieces of K, and then distilled with sodium.

L. Mayer (*A.* 270, 238) recommends the use of charcoal-powder in place of lampblack, and starch-paste rather than oil.—2. Gattermann (*B.* 22, 186) places impure amorphous Si (containing some Mg, &c.), prepared as described under **SILICON**, **Preparation**, No. 1, in a tube a.

2 cms. wide, leaving a space of c. 1 cm. above the Si along the tube; he bends this tube at right angles, and connects it with a U-tube placed in a freezing mixture; he then passes dry Cl through the apparatus, while he heats the tube, laid in an iron trough in a gas-furnace so that the tips of the flames just touch the iron trough. The temperature must not get too high, else the Si glows, and  $MgCl_2$  and O are formed, and the O oxidises the Si to  $SiO_2$ .

*Properties.*—A colourless, very clear, and very mobile liquid, with a disagreeable odour resembling that of cyanides; reddens litmus; fumes in moist air. Does not become viscid at  $-75^\circ$  (Haase, B. 26, 1052).

*Reactions and Combinations.*—1. Heated to redness with hydrogen a little  $SiHCl_3$  is formed (Friedel a. Ladenburg, Bl. [2] 12, 92).—2. Oxichlorides are produced by the action of oxygen under the influence of induction sparks (Troost a. Hautefeuille, A. Ch. [5] 7, 465).—3.  $SiCl_4$  is decomposed by passing the vapour with dry air through a white-hot tube, giving  $SiOCl_2$  and Cl (F. a. L., l.c.). Berthelot (A. Ch. [5] 15, 185) says that  $SiO_2$  is also produced.—4. Water produces  $H_2SiO_3$  and  $HClAq$ .—5. Hydrogen sulphide forms  $SiCl_4.SiH_4$  when  $SiCl_4$  and  $H_2S$  are passed through a red-hot tube (F. a. L., A. 145, 179; Pierre, A. Ch. [3] 24, 300).—6. Many metals—e.g. K, Na, Zn, Ag—withdraw all Cl from  $SiCl_4$  when heated to redness in vapour of  $SiCl_4$  (F. a. L.; cf. Rauter, A. 270, 235).—7. Most metallic oxides form  $SiO_2$  and metallic chlorides when heated with  $SiCl_4$  (R., l.c.);  $CaO$ ,  $MgO$ ,  $Al_2O_3$ , and  $BeO$  form silicates and crystalline  $SiO_2$  (Dauvrée, C. R. 39, 135);  $TiO_2$  is not changed (T. a. H., A. Ch. [5] 7, 476).—8. Decomposed by heating with alkali carbonates, potassium chlorate or nitrate, and various oxidising salts (R., l.c.).—9.  $SiO_2$  and  $HCl$  are produced by reaction with sulphuric acid.—10. Ammonia forms  $SiCl_4.6NH_3$  (Persoz, A. Ch. [2] 44, 315); also, according to Gattermann (B. 22, 194),  $Si.NH_4.N$ .—11. Phosphoretted hydrogen does not react at ordinary temperatures; but at  $-40^\circ$  c. 40 vols. of  $PH_3$  are absorbed by  $SiCl_4$ , forming a solution which does not solidify at  $-60^\circ$  (Besson, C. R. 110, 240). A colourless crystalline compound is produced by compressing  $PH_3$  and  $SiCl_4$ , and then decreasing pressure to 20 atmospheres at  $10^\circ$  (B., l.c.).—12. Heated with sodium silicate,  $NaCl$  is formed. If  $SiCl_4$  vapour is passed through a tube containing fragments of feldspar, at a white heat,  $KCl$ ,  $SiO_2$ , and  $Si_2OCl_2$  are formed (F. a. L., l.c.).

For the compound  $SiHCl_3$  v. SILICON-CHLOROFORM, p. 453.

? SILICON DICHLORIDE  $SiCl_2$ . In the preparation of  $Si_2Cl_6$  by the reaction of  $SiCl_4$  with Si, Troost a. Hautefeuille (A. Ch. [5] 7, 463) obtained a liquid which took fire when heated in air, and reacted with ice-cold water to form a hydroxide of Si having reducing properties.

Silicon, chlorobromides of, v. SILICON-BROMOCHLORIDES, p. 458.

Silicon, chlorohydrosulphide of,  $SiCl_4.SH_3$  (Trichloro-silico-mercaptan.) Mol. w. 167.39. This compound may be looked on as a derivative of hypothetical ortho-thio-silicic acid  $Si(SH)_4$ , obtained by replacing 8SH by 8Cl.

Prepared by passing dry  $H_2S$  into  $SiCl_4$  in a

retort, and then passing the mixed vapours of  $H_2S$  and  $SiCl_4$  through a red-hot porcelain tube connected with a receiver surrounded by a freezing mixture, and fractionating the liquid that condenses (Friedel a. Ladenburg, A. 145, 179). Colourless liquid, with sharp, disgusting smell; boils at  $96^\circ$ ; S.G. 1.45. V.D. 88.5 at c.  $167^\circ$ . Decomposed by moist air, more rapidly by water, to  $H_2S$ , S,  $HClAq$ , and  $SiO_2.xH_2O$ ; bromine produces  $SiBrCl_3$  and  $HBr$ . Alcohol in excess forms  $Si(OEt)_4$ ,  $H_2S$ , and  $HCl$ ; by reacting in the ratio  $3EtOH:SiCl_4.SH_3$ , F. a. L. (l.c.) obtained a liquid boiling at  $164^\circ$ – $167^\circ$ , probably  $Si(OEt)_4.SH_3$ ; this liquid could not be obtained pure, as it changed to  $Si(OEt)_4$ ,  $HCl$ , and  $H_2S$ .

Silicon, chloro-iodides of, v. SILICON-IODOCHLORIDES, p. 461.

Silicon, compounds of, with carbon and oxygen. According to Colson (Bl. [2] 38, 56), the compound  $SiCO_2$  is formed by heating Si with benzene vapour, the compound  $Si_2C_2O_2$  by heating Si to whiteness in a carbon crucible, and the compound  $Si_2C_2O$  by heating Si in  $CO_2$ .

Silicon, compound of, with carbon and sulphur. Colson (Bl. [2] 38, 56) says that a compound, to which he gives the formula  $Si_2C_2S$ , is produced by heating Si to a white heat in  $CS_2$  vapour.

Silicon, compounds of, with hydrogen and oxygen. The compounds of the form  $SiO_2.xH_2O$  are described under SILICA, HYDRATES of (p. 447); the compounds  $Si_2H_2O_2$  and  $Si_2H_2O$  are described as silico-formic anhydride and silico-oxalic acid respectively (pp. 455, 463). Wöhler (A. 127, 257) obtained a substance, by the decomposition of impure Ca silicide by  $HClAq$ , to which he gave the name *silicone*, and either the composition  $Si_2H_2O_2$  or  $Si_2H_2O$ . On account of the yellow colour of this body, Miller proposed to call it *chryseone*. Silicone is described as orange-yellow leaflets, insol. water, alcohol,  $CS_2$ ,  $SiCl_4$ , or  $PCl_5$ ; when heated below redness it takes fire, burning to  $SiO_2$  and amorphous Si; heated out of air, H is given off and  $SiO_2$  and amorphous Si remain; not acted on by Cl, fuming  $HNO_3$ , or conc.  $H_2SO_4$ ; caustic alkali solutions, even dilute  $NH_3Aq$ , produce  $SiO_2$  with rapid evolution of H; acts as an energetic reducer towards solutions of many metallic salts.

Silicon, fluorides of. The existence of any compound of Si and F except  $SiF_4$  is doubtful. Troost a. Hautefeuille (A. Ch. [5] 7, 464) obtained a fine dust by passing  $SiF_4$  over molten Si and suddenly cooling, which was probably a lower fluoride than  $SiF_4$ .

SILICON TETRAFLUORIDE  $SiF_4$ . Mol. w. 104.8.

*Formation.*—1. By passing  $BF_3$  vapour through a red-hot porcelain tube (Troost a. Hautefeuille (A. Ch. [5] 7, 464).—2. By the interaction of  $HFAq$  and  $SiO_2$  or silicates.

*Preparation.*—A fair-sized flask is one-third filled with a mixture of equal parts of powdered  $CaF_2$  and quartz or white sand; sufficient conc.  $H_2SO_4$  is added to thoroughly moisten the mixture; the flask is gently warmed, and the gas that comes off is collected over Hg ( $2CaF_2 + 2H_2SO_4 + SiO_2 = 2CaSO_4 + 2H_2O + SiF_4$ ).

*Properties.*—A colourless gas, with a disagreeable odour and sour taste; reddens dry litmus paper; fumes strongly in air. V.D. 51.9

(Dumas, *A. Ch.* [2] 83, 368). Condensed to a colourless mobile liquid at  $-106.5^\circ$  and 9 atmos. pressure (Faraday, *T.* 1845, 155). According to Olszewski (*M.* 5, 127)  $\text{SiF}_4$  solidifies at  $-102^\circ$ . Acts as a powerful poison (v. Cameron, *Dublin J. of Med. Sci.* Jan. 1887).

**Reactions.**—1. Decomposed by electric sparks with separation of Si (*T. a. H.*, *C. R.* 43, 443).—2. Potassium and iron, when hot, burn in  $\text{SiF}_4$ , forming fluorides and Si.—3. Moist air forms  $\text{Si}_2\text{O}_5\text{F.OH}$  (Landolt, *A. Suppl.* 4, 27, and v. DIMETASILICIO FLUORHYDRIN, *infra*).—4. Water absorbs  $\text{SiF}_4$ , forming  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$  and  $\text{H}_2\text{SiF}_6\text{Aq}$  (v. SILICOFLUORHYDRIC ACID, p. 454).—5. Ammonia forms  $\text{SiF}_4 \cdot 2\text{NH}_3$  (*J. Davy*, *T.* 1812, 352); also, according to Harris (*C. C.* 1889 (ii), 283),  $\text{SiNH}_3\text{N}$  (v. SILICON AMIDONITRIDE, p. 457).

**Combinations.**—1. Combines with dry phosphoretted hydrogen, when the gases are strongly compressed at  $-22^\circ$  and 50 atmospheres in the ratio  $2\text{PH}_3:3\text{SiF}_4$ , to form lustrous crystals (Besson, *C. R.* 110, 80).—2. Alcohol absorbs  $\text{SiF}_4$  freely, forming an acid liquid which gives off  $\text{SiF}_4$  in the air (Knop, *J.* 1858, 146).—3.  $\text{SiF}_4$  is absorbed by many metallic oxides.

**Dimetasilicic fluorhydrin**  $\text{Si}_2\text{O}_5\text{F.OH.F}$ . Landolt (*A. Suppl.* 4, 27) obtained this compound as a white crystalline solid (v. also Schiff, *J.* 1865, 196).

Silicon, haloid compounds of. The compounds of Si with halogens belong to the forms  $\text{Si}_x\text{X}_y$  and  $\text{SiX}_n$ ; the compounds  $\text{SiX}_n$ , where X is a single halogen, have been gasified, and the compound  $\text{Si}_2\text{Cl}_6$  has also been gasified. The formulae are probably all molecular. There are also indications of the existence of some compounds of the type  $\text{SiX}_n$ . Besides the compounds where X is a single halogen, there exist the compounds  $\text{SiXX}'$ ,  $\text{SiX}_2\text{X}'$ , and  $\text{SiX}_3\text{X}'$ , where X and X' are Br and Cl, I and Cl, and I and Br respectively; the only one of these compounds that has been gasified is  $\text{SiBr}_2\text{Cl}$ .

Silicon, hydrides of. The compound  $\text{SiH}_4$  has been isolated and examined. The existence of another hydride, probably  $\text{Si}_2\text{H}_6$ , is likely.

**SILICON TETRAHYDRIDE**  $\text{SiH}_4$ . (*Siliciuretted hydrogen*.) Mol. w. 32.3. Si and H do not combine directly, even in the electric arc (Friedel, *C. R.* 73, 497).

**Formation.**—1. Al containing Si is made the positive pole in  $\text{NaClAq}$  (Buff a. Wöhler, *A.* 103, 218).—2. Crude Mg silicide is decomposed by dilute  $\text{HClAq}$  (v. Preparation). These processes yield mixtures of  $\text{SiH}_4$  and  $\text{H}_2$ .—3. By the reaction of Na with  $\text{SiH(OEt)}_3$  (v. Preparation).

**Preparation.**—1. Small pieces of Na are dropped into  $\text{SiH(OEt)}_3$  (v. *infra*), and the liquid is gently warmed; the escaping gas is allowed to drive out the air (if the Na or  $\text{SiH(OEt)}_3$  was moist H comes off, and the gas takes fire), and is then collected over Hg (Friedel a. Ladenburg, 143, 123). The  $\text{SiH(OEt)}_3$  is prepared by adding dry absolute alcohol to pure  $\text{SiHCl}_3$  in a long-necked flask, in the ratio  $3\text{EtOH}:\text{SiHCl}_3$ , distilling after some time, and collecting the liquid that boils from  $134^\circ$  to  $137^\circ$ .—2. Impure  $\text{SiH}_4$ , mixed with considerable quantities of  $\text{H}_2$ , is prepared by placing coarsely-pulverised crude Mg silicide (for preparation, v. *infra*) in a small

two-necked flask, fitted with a funnel tube and a short wide delivery tube; the flask and delivery tube are quite filled with water from which all air has been driven out by boiling, the delivery tube is made to dip under boiled water, and the bell-jar to receive the gas is filled with boiled water; conc.  $\text{HClAq}$  is added, little by little, by the funnel tube. The gas, which comes off very rapidly, is collected in a bell-jar fitted with a stop-cock; this jar is then connected with a U-tube containing  $\text{CaCl}_2$  and carrying a short, narrow piece of glass tubing, which is made to dip under a dry vessel full of Hg. By depressing the bell-jar, the gas is forced out; it burns in the tubes till the air is exhausted, when it passes into the vessel full of Hg, where it is collected.

**Preparation of the crude Mg silicide.** A mixture of 1 part finely-powdered, dry, white sand and  $1\frac{1}{2}$  parts Mg powder is heated in a stout glass tube; reduction takes place with production of much light, and a blue-grey, semi-molten mass is obtained (Gattermann, *B.* 22, 186). For other methods of preparing the Mg silicide required, v. Wöhler (*A.* 137, 369), Warren (*C. N.* 58, 215), and Mermet (*B.* [2] 47, 306).

**Properties.**—A colourless gas; insol. water; liquefied at  $-11^\circ$  and 50 atmos.,  $-7$  and 70 atmos., or  $-1^\circ$  and 100 atmos. pressure (Ogier, *A. Ch.* [5] 20, 6). V.D. 15.9 (F. a. L., *A.* 143, 123). H.F. ( $[\text{SiH}_4]$ ) = 32,900 (O. l.c.). Does not react with N, NO,  $\text{NH}_3$ ,  $\text{H}_2\text{SO}_4\text{Aq}$ , or  $\text{HClAq}$ .

**Reactions.**—1. Decomposed completely to Si and H by heating to above  $400^\circ$  (O. l.c.).—2. Induction sparks cause increase of volume from 100 to 121–129; H is produced, and yellow solid separates, probably  $\text{Si}_2\text{H}_6$  (v. DISILICON TRIHYDRIDE, *infra*).—3.  $\text{SiH}_4$  takes fire in air when slightly heated, or when the pressure is decreased; if the pure gas is passed into a tube filled with Hg, the pressure is lowered to 100–150 mm., and air is admitted, the gas takes fire (F. a. L., l.c.). The gas as prepared from Mg silicide is mixed with  $\text{H}_2$ , and takes fire in air at ordinary temperature and pressure.—4. Burns in chlorine with violent explosion.—5. Conc. potash solution forms  $\text{K}_2\text{SiO}_3$  and H; the volume of H is four times that of the  $\text{SiH}_4$  ( $\text{SiH}_4 + 2\text{KOH} + \text{H}_2\text{O} = \text{K}_2\text{SiO}_3 + 8\text{H}$ ) (F. a. L., l.c.).—6. Reduces solutions of many metallic salts; ppts. Ag and Si from  $\text{AgNO}_3\text{Aq}$ , Pd from Pd salts, Cu silicide from  $\text{CuSO}_4\text{Aq}$ , &c. Does not react with  $\text{PtCl}_4\text{Aq}$  or  $\text{Pb(C}_2\text{H}_3\text{O}_2)_4\text{Aq}$ .—7. The action of electric discharges on  $\text{SiH}_4$ , mixed with nitrogen produces  $\text{NH}_3$ , and (?)  $\text{Si}_2\text{H}_6$ , which combines with some of the N (Ogier, *A. Ch.* [5] 20, 81).

**DISILICON TRIHYDRIDE**  $\text{Si}_2\text{H}_6$ . This formula is given by Ogier (*A. Ch.* [5] 20, 81) to a yellow solid obtained by the action of induction sparks on  $\text{SiH}_4$ . The composition of the substance is somewhat doubtful. It takes fire when rubbed or heated in air; heated in H or N, inflammable  $\text{SiH}_4$  is produced, or at higher temperatures Si and H are formed.

Silicon hydrogen bromides v. SILICO-BROMOFORM, p. 453, and SILICO-ETHANE, PENTABROMO-DERIVATIVE or  $(\text{Si}_2\text{HBr})_n$ , p. 454.

Silicon hydrogen chloride v. SILICO-CHLOROFORM, p. 453.

**Silicon hydrogen iodide v. SILICO-IODOFORM, p. 455.**

**Silicon, hydroxides of, v. SILICA, HYDRATES OF, p. 447; SILICO-FORMIC ACID, p. 455; SILICO-FORMIC ANHYDRIDE, p. 455; SILICO-OXALIC ACID, p. 463; and *Silicone*, under SILICON, compounds of, WITH HYDROGEN AND OXYGEN, p. 459.**

**Silicon, iodides of.** Two compounds have been isolated,  $\text{SiI}_2$  and  $\text{SiI}_4$ , and a third, which is probably  $\text{SiI}_3$ , seems also to exist.

**SILICON TETRA-IODIDE  $\text{SiI}_4$ .** Mol. w. 534.42. Melts at  $120.5^\circ$ ; boils at  $290^\circ$ . V.D. at  $360^\circ = 268.5$ . H.F.  $[\text{SiF}_4] = 58,000$  (Berthelot).

**Preparation.**—1. The crude product obtained by reducing a mixture of 4 parts fine white sand by heating with 1 part Mg powder (v. *SILICON, Preparation of*, No. 1, p. 456) is strongly heated in a mixture of dry  $\text{CO}_2$  and I vapour, in a tube which projects c. 20 cm. from the furnace;  $\text{SiI}_4$  collects in the cold part of the tube, it is dissolved in  $\text{CS}_2$  (1 part  $\text{CS}_2$  dissolves c. 2.2 parts  $\text{SiI}_4$ ), shaken with Hg till colourless, and the  $\text{CS}_2$  is evaporated by passing dry  $\text{CO}_2$  through it at the lowest possible temperature (Gattermann, *B.* 22, 190).—2. A mixture of  $\text{CO}_2$  and I vapour is passed over Si strongly heated in a porcelain tube; the  $\text{SiI}_4$  that collects in the cold part of the tube is purified as in 1 (Friedel, *A.* 149, 96).

**Properties and Reactions.**—Colourless, transparent, regular octahedra; isomorphous with  $\text{Cl}_4$ . (For M.P., &c., v. *supra*.) The vapour burns when heated in air, with separation of I. Water produces  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$  and  $\text{HIAg}$ . Alcohol forms  $\text{EtI}$ ,  $\text{HI}$ , and  $\text{SiO}_2$ . Ether, at  $100^\circ$ , produces  $\text{Si}(\text{OEt})_4$  and  $\text{EtI}$  (F., l.c.).

**SILICON HEXA-IODIDE  $\text{SiI}_6$ .** Formula probably molecular, from analogy of  $\text{SiCl}_6$ . Prepared by heating  $\text{SiI}_4$  with finely-divided Ag (formed by reducing  $\text{AgCl}$ ) to  $290^\circ$ – $300^\circ$  for some hours, removing  $\text{SiI}_4$  by washing with a little dry  $\text{CS}_2$  (1 part  $\text{CS}_2$  dissolves c. 26 parts  $\text{SiI}_6$  and c. 2.2 parts  $\text{SiI}_4$ ), dissolving in much hot  $\text{CS}_2$ , and crystallising (Friedel & Ladenburg, *A.* 203, 254). Colourless, six-sided, double refractive plates. Melts at  $250^\circ$  in *vacuo*, with partial decomposition. When heated, decomposes to  $\text{SiI}_4$  and a substance that is probably  $\text{SiI}_3$ . Fumes in air; with water gives  $\text{H}_2\text{SiO}_4$  and  $\text{HIAg}$ .

**SILICON DI-IODIDE.** The yellow solid that is formed by heating  $\text{SiI}_4$  is probably  $\text{SiI}_2$ ; it is insol. in the ordinary solvents; with water becomes grey, perhaps forming  $\text{H}_2\text{SiO}_2$  (v. *SILICO-FORMIC ACID*, p. 455) (Friedel & Ladenburg, *A.* 203, 247).

For the compound  $\text{SiHI}$ , v. *SILICO-IODOFORM*, p. 455.

**Silicon, iodobromides of.** Three compounds, corresponding with the three bromochlorides and the three iodochlorides, are formed by passing  $\text{IBr}$  (alone or mixed with H) over crystalline Si heated to dull redness; also by passing the vapour of a solution of I in  $\text{SiBr}_4$  over crystalline Si at a low red heat (Besson, *C. R.* 112, 1447). The compounds are solids which decompose in air with separation of I; they all combine with  $\text{NH}_3$  to form white compounds that are decomposed by water.

**SILICON IODOTRI-BROMIDE  $\text{SiIBr}_3$ .** Melts at  $14^\circ$  and boils at  $192^\circ$ . Prepared as described above, also (probably) by the interaction of I and

$\text{SiHBr}_3$  at  $200^\circ$ – $250^\circ$ , also by passing HI over  $\text{SiBr}_4$  heated to low redness (B., l.c.).

**SILICON DI-IODODIBROMIDE  $\text{SiI}_2\text{Br}_2$ .** Melts at c.  $88^\circ$  and boils at  $230^\circ$ – $281^\circ$ .

**SILICON TRI-IODOBROMIDE  $\text{SiI}_3\text{Br}$ .** Melts at c.  $55^\circ$  and boils at c.  $255^\circ$ .

**Silicon, iodochlorides of.** Three compounds have been isolated, corresponding with the three bromochlorides, and the three iodobromides. The V.D. of none has been determined, but from the analogy with the bromochlorides the simplest formulae are probably molecular.

**SILICON IODOTRICHLORIDE  $\text{SiICl}_3$ .** Obtained by passing HI mixed with  $\text{SiCl}_4$  vapour through a red-hot tube, also by the interaction of HI and  $\text{SiHCl}_3$  at  $200^\circ$ – $250^\circ$ , also by distilling  $\text{ICl}$  over crystallised Si heated to redness (Besson, *C. R.* 112, 60, 1314). A colourless liquid, boiling at  $113^\circ$ – $114^\circ$ ; fumes in air; decomposed by water; I separates on standing, especially in sunlight. With  $\text{NH}_3$  forms white amorphous  $\cdot 2\text{SiCl}_3 \cdot 11\text{NH}_3$ .

**SILICON DI-IODODICHLORIDE  $\text{SiI}_2\text{Cl}_2$ .** Formed from HI and  $\text{SiCl}_4$  also from  $\text{ICl}$  and Si; also by heating HI with  $\text{SiI}_2\text{Cl}_2$  at  $250^\circ$ . Colourless liquid, boiling at  $172^\circ$ . With  $\text{NH}_3$  forms amorphous  $\text{SiI}_2\text{Cl}_2 \cdot 5\text{NH}_3$  (B., l.c.).

**SILICON TRI-IODOCHLORIDE  $\text{SiI}_3\text{Cl}$ .** A solid obtained in preparation of the two former compounds; melts at  $2^\circ$ . Fumes in air, with separation of I.

**Silicon, nitrides of.** Schutzenberger (*C. R.* 114, 1089) obtained small quantities of a compound to which he gave the formula  $\text{Si}_2\text{N}_4$ , along with a carbide of Si, by heating 1 part Si and 2 parts  $\text{SiO}_2$  in a covered carbon crucible, imbedded in lampblack in an outer crucible, to bright redness for some hours. By passing  $\text{NH}_3$  through a porcelain tube kept at a white heat, Colson (*C. R.* 94, 1710) found a black layer in the hottest part of the tube, which was probably a mixture of Si and nitride of Si. A compound of Si, N, and H, probably  $\text{Si}_3\text{NH}_4\text{N}$ , was obtained by Harris (*C. C.* 1889 (ii) 293) by the reaction of  $\text{NH}_3$  with  $\text{SiCl}_4$  or  $\text{SiF}_4$ .

**Silicon, oxide of,  $\text{SiO}_2$ ; v. SILICA, p. 446.**

**Silicon, oxychlorides of.** The compound  $\text{Si}_2\text{OCl}_4$  is formed by heating  $\text{SiCl}_4$  vapour in air or O. According to Troost & Hautefeuille (*Bl.* [2] 35, 360) several oxychlorides are formed by passing a mixture of  $\text{SiCl}_4$  vapour and O through a red-hot tube, or, better, by passing a mixture of 1 vol.  $\text{Cl}_2$  and  $\frac{1}{2}$  to  $\frac{1}{3}$  vol. O over crystalline Si heated to not above  $800^\circ$ . T. a. H. isolated the following oxychlorides:—

$\text{Si}_2\text{O}_2\text{Cl}_6$ ; liquid, b.p.  $152^\circ$ – $154^\circ$ .

$\text{Si}_2\text{O}_3\text{Cl}_4$ ; liquid, b.p.  $198^\circ$ – $202^\circ$ .

$\text{Si}_2\text{O}_4\text{Cl}_2$ ; oily liquid, b.p. above  $400^\circ$ .

$\text{Si}_2\text{O}_5\text{Cl}_2$ ; solid, m.p. above  $400^\circ$ .

**SILICON OXYCHLORIDE  $\text{Si}_2\text{OCl}_4$ .** (*Perchlorosilico-methyl ether* ( $\text{SiCl}_3$ )<sub>2</sub>O.) Mol. w. 284.78. Prepared by passing vapour of  $\text{SiCl}_4$  through a porcelain tube heated in a wind furnace burning coke, condensing the product, repeating the operation with the portion which boils above  $70^\circ$ , fractionating, and separating the liquid boiling at  $137^\circ$ – $138^\circ$  (Friedel & Ladenburg, *A.* 147, 355). A colourless liquid, boiling at  $137^\circ$ – $138^\circ$ . V.D. 144 at c.  $200^\circ$ . Fumes in air, decomposed by water to  $\text{HClAg}$  and  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ . Miscible in all proportions with  $\text{CHCl}_3$ ,  $\text{CCl}_4$ ,  $\text{CS}_2$ ,

$\text{SiCl}_4$ , and  $\text{Et}_2\text{O}$ . Alcohol produces  $\text{Si}_2\text{O}_3(\text{Et})_2$ ; zinc-ethide at  $180^\circ$  forms  $\text{SiEt}_2$  and  $\text{Si}_2\text{OEt}_2$  (F. a. L., l.c.).

The compound  $\text{SiF}_2\text{O}_2\text{Cl}_2$  is described as **SILICOPHOSPHORIC OXYCHLORIDE** (p. 461).

**Silicon, oxysulphide of.** According to Colson (*Bl.* [2] 88, 56), a compound  $\text{SiOS}$  is formed, along with  $\text{SiS}$  and  $\text{Si}_2\text{SCl}_2$ , by heating  $\text{Si}$  to white heat in  $\text{CS}_2$ .

**Silicon, sulphides of.** The only compound of  $\text{Si}$  and  $\text{S}$  certainly isolated is  $\text{SiS}_2$ . Colson (*Bl.* [2] 88, 56) says that *silicon monosulphide*,  $\text{SiS}$ , is produced, along with  $\text{SiOS}$  and  $\text{Si}_2\text{SCl}_2$ , by heating  $\text{Si}$  to white heat in  $\text{CS}_2$ ; he describes  $\text{SiS}$  as a yellow solid, decomposed by water giving off  $\text{H}_2\text{S}$ , sol. in very dilute  $\text{KOH}$ aq with evolution of  $\text{H}_2$ .  $\text{SiS}$  is also said to be formed, along with  $\text{SiS}_2$ , by heating  $\text{Si}$  to redness in  $\text{H}_2\text{S}$  (Sabatier, *Bl.* [2] 38, 153).

**SILICON DISULPHIDE**  $\text{SiS}_2$ . Mol. w. not determined. Sabatier (*Bl.* [2] 38, 153) gives  $\text{H.F.} [\text{Si}, \text{S}^*] = 19,900$ . Amorphous  $\text{Si}$  and  $\text{S}$  combine when strongly heated (Berzelius). Prepared by heating  $\text{Si}$  to redness in a stream of dry  $\text{H}_2\text{S}$ ; the other products are a yellow solid, probably  $\text{SiS}$ , and a brown substance that is likely a mixture of  $\text{SiS}_2$  and  $\text{SiS}$ , or of  $\text{SiS}_2$  and  $\text{Si}$  (*S.*, l.c.; v. also Fremy, *A. Ch.* [3] 38, 324). Also prepared by strongly heating dried pellets of oil and  $\text{SiO}_2$  (separated from  $\text{SiF}_4$ ) in a slow stream of dry  $\text{CS}_2$ , quickly separating the white needles that form on the cooler part of the tube, and keeping in a closed tube (Fremy, l.c.). The residue that remains on distilling the products of the interaction of  $\text{SiCl}_4$  and  $\text{H}_2\text{S}$  (v. **SILICON CHLOROHYDROSULPHIDE**, p. 459) contains  $\text{SiS}$  and  $\text{S}$ ;  $\text{S}$  may be removed by carefully heating in a stream of  $\text{N}$  (Gay-Lussac & Thénard, *A. Ch.* [2] 69, 204). Long, lustrous, white needles; volatilised at very high temperatures (Fremy, l.c.). Unchanged in dry air at ordinary temperatures; decomposed by moist air to  $\text{H}_2\text{S}$ , and crystalline  $\text{SiO}_2$ , pseudomorphous with  $\text{SiS}_2$ ; burns to  $\text{SO}_2$  and  $\text{SiO}_2$  when heated in air. Decomposed rapidly by water to  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$  and  $\text{H}_2\text{S}$ ; also decomposed by alcohol and ether (Fremy, l.c.).  $\text{HNO}_3$  oxidises rapidly, producing  $\text{H}_2\text{SO}_4$ . M. M. P. M.

**Silicon, sulphocyanide of;** v. p. 463.

#### SILICON, ORGANIC COMPOUNDS OF.

**Silicic ethers** are described elsewhere—v. **AMYL, AMYLPHENYL, ETHYL, METHYL, PHENYL, THYNYL, TOLYL, and XYLYL SILICATES**.

**Tetra-methyl-silicane**  $\text{SiMe}_4$ . Mol. w. 88. ( $31^\circ$ ). V.D. 3.08 (calc. 3.04). Formed by heating  $\text{SiCl}_4$  with  $\text{ZnMe}_2$  at  $120^\circ$  (Friedel & Crafts, *A.* 136, 203). Light oil, burning with bright flame emitting  $\text{SiO}_2$ . Not attacked by potash or  $\text{HNO}_3$  (*S.G.* 1.4).

**Tetra-ethyl-silicane**  $\text{SiEt}_4$ . Mol. w. 144. ( $153^\circ$ ). V.D. 5.13 (calc. 4.99). *S.G.* 2.834. Prepared by heating  $\text{SiCl}_4$  with  $\text{ZnEt}_2$  at  $160^\circ$ . Formed also by the action of  $\text{ZnEt}_2$  and  $\text{Na}$  on ethyl silicate (Friedel & Crafts, *Bl.* 1863, 468; 1865, 358; *A.* 127, 31; 138, 19). Oil, insol.  $\text{H}_2\text{SO}_4$ . Chlorine forms liquid  $\text{Et}_2\text{SiCl}_2\text{HCl}$  ( $185^\circ$ ), converted by alcoholic  $\text{KOAc}$  at  $180^\circ$  into  $\text{Et}_2\text{SiCl}_2\text{H}_2\text{OAc}$  ( $208^\circ$ – $214^\circ$ ), whence alcoholic potash at  $120^\circ$  forms oily  $\text{Et}_2\text{SiCl}_2\text{H}_2\text{OH}$  ( $190^\circ$ ).

**Hexa-ethyl-silicane**  $\text{Si}_2\text{Et}_6$ . ( $252^\circ$ ). *S.G.* 3.851;  $\eta$  840. V.D. 8.6 (calc. 7.98).

Formed by distilling  $\text{Si}_2\text{I}_4$  with  $\text{ZnEt}_2$  (Friedel & Ladenburg, *A.* 203, 251). Oil, burning with bright flame.

**'Silicopropionic acid'**  $\text{EtSiO.OH}$ . Got by heating its ortho- ether with  $\text{HIAq}$  (Ladenburg, *A.* 159, 271; 164, 305). Amorphous powder, insol. water and  $\text{Na}_2\text{CO}_3\text{aq}$ , sol. conc.  $\text{KOH}$ aq.

**Methyl ortho- ether**  $\text{EtSi(OMe)}_2$ . ( $126^\circ$ ). *S.G.* 2.9747. Formed from  $\text{Si(OMe)}_2$ , sodium, and  $\text{ZnEt}_2$  (Ladenburg, *B.* 5, 1081). Oil.

**Ethyl ortho- ether**  $\text{EtSi(OEt)}_2$ . ( $159^\circ$ ). *S.G.* 2.927. Formed by the action of  $\text{Na}$  and  $\text{ZnEt}_2$  on  $\text{ClSi(OEt)}_2$  or  $\text{Si(OEt)}_2$ . Oil. Converted by  $\text{BzCl}$  into  $\text{EtOBz}$  and  $\text{EtSiCl}_2$  ( $100^\circ$ ), which fumes in the air and is converted by water into silicopropionic ether.

**'Silicodiethyl ether'**  $\text{Et}_2\text{Si(OEt)}_2$ . ( $166^\circ$ ). *S.G.* 2.875. V.D. ( $\text{H}=1$ ) 87 (calc. 88). Formed from  $\text{Na}$ ,  $\text{ZnEt}_2$ , and silicic ether. Oil, sol. alcohol and ether.  $\text{AcCl}$  (1 mol.) at  $200^\circ$  forms  $\text{EtOAc}$  and  $\text{Et}_2\text{SiCl(OEt)}$  ( $147^\circ$ ). A larger quantity (2 mols.) of  $\text{AcCl}$  at  $250^\circ$  forms  $\text{Et}_2\text{SiCl}_2$  ( $129^\circ$ ), which is decomposed by water, forming syrupy  $\text{SiEt}_2\text{O}$  (above  $360^\circ$ ), which may also be got by boiling  $\text{SiEt}_2\text{(OEt)}_2$  with  $\text{HIAq}$ .

**'Silicoheptyl ether'**  $\text{SiEt}_7\text{.OEt}$ . Mol. w. 160. ( $153^\circ$ ). *S.G.* 2.840. V.D. ( $\text{H}=1$ ) 80.8 (calc. 80). Formed from  $\text{SiEt}_7\text{(OEt)}_2$ ,  $\text{Na}$ , and  $\text{ZnEt}_2$ . Oil, sol. alcohol and ether. Sol. conc.  $\text{H}_2\text{SO}_4$ .  $\text{AcCl}$  at  $180^\circ$  forms  $\text{SiEt}_7\text{Cl}$  ( $144^\circ$ ), *S.G.* 2.925, a fuming liquid converted by  $\text{NH}_3\text{aq}$  into  $\text{SiEt}_7\text{OH}$ .

**Tri-ethyl-silicol**  $\text{SiEt}_3\text{OH}$ . Mol. w. 132. ( $154^\circ$ ). *S.G.* 2.871. Formed by dropping  $\text{SiEt}_3\text{OEt}$  into  $\text{NH}_3\text{aq}$ , or by heating it with  $\text{Ac}_2\text{O}$  at  $250^\circ$  and decomposing the resulting  $\text{SiEt}_3\text{OAc}$  with  $\text{Na}_2\text{CO}_3\text{aq}$ . Thick liquid, smelling like camphor. Insol. water, miscible with alcohol and ether. Burns with bright flame. Sodium forms  $\text{SiEt}_3\text{ONa}$ , which, in ethereal solution, combines with  $\text{CO}_2$ , forming  $\text{SiEt}_3\text{CO}_2\text{Na}$ , an amorphous deliquescent solid, decomposed at a red heat into  $\text{Si}_2\text{Et}_4\text{O}$  and  $\text{Na}_2\text{CO}_3$ .  $\text{AcCl}$  forms  $\text{HOAc}$  and  $\text{SiEt}_3\text{Cl}$ .  $\text{HIAq}$  at  $200^\circ$  forms ethane and  $\text{SiEt}_3\text{O}$ . Oxidising agents have no action. Fuming  $\text{H}_2\text{SO}_4$  forms  $\text{EtSiO}_2\text{H}$ , ethane,  $\text{H}$ , and  $\text{SO}_2$ .

**Acetyl derivative**  $\text{SiEt}_3\text{OAc}$ . ( $168^\circ$ ). *S.G.* 2.903. Formed by heating  $\text{SiEt}_3\text{OEt}$  with  $\text{Ac}_2\text{O}$  at  $250^\circ$ . Liquid with ethereal odour.

**'Silicoheptyl oxide'**  $(\text{SiEt}_7)_2\text{O}$ . Mol. w. 246. ( $231^\circ$ ). *S.G.* 2.859. Formed as above, and also by the action of  $\text{P}_2\text{O}_5$  on tri-ethyl-silicol. Got also from  $\text{SiEt}_7\text{Cl}$  and  $\text{KOH}$ aq. Colourless syrup, sol.  $\text{H}_2\text{SO}_4$ , and separated unchanged on dilution, if heating be avoided.

**Tri-ethyl-silicane**  $\text{SiEt}_3\text{H}$ . ( $107^\circ$ ). *S.G.* 2.751. V.D. ( $\text{H}=1$ ) 59 (calc. 58). Formed, together with  $\text{SiEt}_4$ , by the action of excess of  $\text{ZnEt}_2$  and  $\text{Na}$  on  $\text{Et}_2\text{SiO}_2$ . Liquid, insol. water and  $\text{H}_2\text{SO}_4$ , sol. alcohol and ether. Fuming  $\text{H}_2\text{SO}_4$  converts it into  $(\text{SiEt}_3)_2\text{O}$ .  $\text{HNO}_3$  attacks it vigorously. Bromine added slowly to the cooled liquid forms  $\text{SiEt}_3\text{Br}$  ( $161^\circ$ ), which is converted by  $\text{NaOHAq}$  into  $(\text{SiEt}_3)_2\text{O}$ , and by  $\text{NH}_3\text{aq}$  into  $\text{SiEt}_3\text{OH}$ .

**Silicoformic acid. Ethyl ortho- ether**  $\text{SiH(OEt)}_2$ . ( $194^\circ$ ). Formed from  $\text{SiHCl}_2$  and absolute alcohol (Friedel & Ladenburg, *A.* 143, 123; *Bl.* [2] 7, 323; Gattermann, *B.* 22, 190). Hygroscopic liquid, decomposed by alkalis with

evolution of H. Sodium decomposes it into  $\text{SiH}_4$  and  $\text{Et}_2\text{SiO}_2$ .

Chloro-silicoformic ether v. ETHYL SILICATE.

'Silicoacetic acid.' *Ethyl ortho-ether*  $\text{CH}_3\text{Si}(\text{OEt})_2$ . (145°-151°). S.G. 2-928. Formed by heating silicic ether with  $\text{ZnMe}_2$ . Oil, sol. alcohol. Converted by  $\text{HIAq}$  into amorphous silico-acetic acid  $\text{CH}_3\text{SiO}_2\text{H}$ , which is insol. water and ether (Ladenburg, B. 6, 1029).

The term silicoacetic acid is also sometimes used to denote  $\text{H}_2\text{SiO}_3$ , which is got by decomposing  $\text{Si}_2\text{I}_2$  by water at 0° (Friedel a. Ladenburg, A. 203, 249; v. SILICO-OXALIC ACID, *infra*). A compound  $\text{Si}_2\text{O}_3$  is formed, as a bottle-green powder, by heating silicon to whiteness in a crucible lined with lampblack. It is insol. KOHAq and HFAq (Colson, C. R. 94, 1316).

Tetra-propyl-silicane  $\text{Si}(\text{C}_2\text{H}_5)_4$ . (213°). S.G. 2-7979;  $\frac{1}{2}$ -7883. V.D. 99-7 (obs.). Formed, together with  $\text{SiHPr}_2$ , by heating  $\text{ZnPr}_2$  (2 pts.) with  $\text{SiHCl}$  (1 pt.) at 150° (Pape, B. 14, 1872; A. 222, 370). Colourless oil, sol. alcohol and ether, insol.  $\text{H}_2\text{SO}_4$ . Br has no action in the cold, but on warming it forms oily  $\text{SiCl}_2\text{H}_2\text{Br}$ , converted by alcoholic potash into oily  $\text{SiCl}_2\text{H}_2$  (206°-210°).

Tri-propyl-silicane  $\text{SiHPr}_3$ . (170°). S.G. 2-7723;  $\frac{1}{2}$ -7621. V.D. 82 (obs.). Formed as above. Oil, v. sol. alcohol and ether, insol. conc.  $\text{H}_2\text{SO}_4$ . Burns with bright flame, forming  $\text{SiO}_2$ . Br acts violently, forming  $\text{SiPr}_2\text{Br}$  (213°), a fuming liquid, which is slowly converted by water into  $\text{SiPr}_2\text{OH}$ .

Tri-propyl-silicic  $\text{SiPr}_3\text{OEt}$ . (205°-208°). Formed by the action of  $\text{NH}_4\text{Aq}$  on  $\text{SiPr}_2\text{Br}$ , or of  $\text{Na}_2\text{CO}_3\text{Aq}$  on  $\text{SiPr}_2\text{OAc}$  (Pape). Oil.

Acetyl derivative  $\text{SiPr}_3\text{OAc}$ . (212°-216°). Formed from  $\text{SiPr}_2\text{Br}$  and  $\text{AgOAc}$ . Oil.

Hexa-propyl-di-silicil oxide  $(\text{SiPr}_2)_2\text{O}$ . (280°-290°). Formed by warming  $\text{SiHPr}_2$  with  $\text{H}_2\text{SO}_4$  and, together with  $\text{SiPr}_2\text{OH}$ , by boiling  $\text{SiHPr}_2$  with  $\text{Na}_2\text{CO}_3\text{Aq}$  (Pape, A. 222, 369). Liquid, sol. alcohol, ether, and  $\text{H}_2\text{SO}_4$ .

Silicon sulphocyanide  $\text{Si}(\text{CNS})_4$ . (142° (c. 300°)). Formed by distilling lead sulphocyanide with  $\text{SiCl}_4$  (Miguel, A. Ch. [5] 11, 343). Colourless prisms, insol. ether and  $\text{CS}_2$ , soluble in a solution of  $\text{HCNS}$  in benzene. Burns with violet flame. Dyes the skin red. Decomposed by water into  $\text{HCNS}$  and  $\text{SiO}_2$ .

Tetra-phenyl-silicane  $\text{SiPh}_4$ . [233°]. (above 360°). S.G. 2-10780. Formed from chlorobenzene,  $\text{SiCl}_4$ , and Na in presence of a little  $\text{EtOAc}$  (Polis, B. 18, 1540; 19, 1012; 20, 3331). Dimetric crystals;  $a:b:c = 1:440$ , sol. hot benzene, sl. sol. alcohol and ether. May be sublimed. Sulphonated by fuming  $\text{H}_2\text{SO}_4$ .  $\text{HNO}_3$  forms  $\text{Si}(\text{C}_6\text{H}_4\text{NO}_2)_4$ , [105°], a yellow powder, v. sol. benzene. Converted by  $\text{PCl}_5$  into liquid  $\text{SiPh}_2\text{Cl}_2$  (234° at 90 mm.) and  $\text{SiPh}_2\text{Cl}$  [89°], from which water produces tri-phenyl-silicic  $\text{SiPh}_2\text{OH}$  [141°], which separates from ether in colourless crystals.

Phenyl-tri-chloro-silicane  $\text{SiPhCl}_3$ . (197°). Formed by heating  $\text{SiCl}_4$  with  $\text{HgPh}$ , at 300° (Ladenburg, B. 6, 379). Oil. Decomposed by hot water, or by  $\text{NH}_4\text{Aq}$ , yielding 'silicobenzoic acid'  $\text{SiPh}(\text{OH})_2$  [92°]. Absolute alcohol forms 'silicobenzoic' ethyl ortho-ether  $\text{SiPh}(\text{OEt})_2$  (237°). S.G. 2-1013;  $\frac{1}{2}$ -1006. Silicobenzoic acid is converted at 100° into amorphous 'silicobenzoic anhydride'  $(\text{SiPhO})_2\text{O}$ .

Phenyltriethyl-silicane  $\text{SiPhEt}_3$ . (230°). S.G. 2-904. Formed, together with  $\text{SiEt}_4$  and  $\text{SiPh}_2\text{Et}_2$  (c. 810°), by heating  $\text{SiPhCl}_3$  with  $\text{ZnEt}_2$  at 150°. Oil, smelling like cloves. Yields a bromo-derivative (270°-280°). Cl forms  $\text{SiC}_2\text{H}_5\text{H}_3\text{Cl}$  (260°-265°), S.G. 2-10185.

Tetra-m-tolyl-silicane:  $\text{Si}(\text{C}_6\text{H}_4)_4$ . [151°]. (above 550°). S.G. 2-1119. Formed from m-bromo-toluene,  $\text{SiCl}_4$ , and Na (Polis, B. 19, 1021). Pale-yellow needles (from ether), v. sol. benzene and chloroform, insol. alcohol.

Tetra-p-tolyl-silicane  $\text{Si}(\text{C}_6\text{H}_4)_4$ . [228°]. (above 360°). S.G. 2-1079. Formed from p-bromo-toluene,  $\text{SiCl}_4$ , and Na (Polis, B. 18, 1542). Colourless crystals, sol. benzene.

p-Tolyl-tri-chloro-silicane  $\text{C}_6\text{H}_4\text{SiCl}_3$ . (219°). Formed from  $\text{Hg}(\text{C}_6\text{H}_4)_2$  and  $\text{SiCl}_4$  at 310° (Ladenburg, A. 173, 165). Fuming liquid, decomposed by water. Converted by  $\text{NH}_4\text{Aq}$  into viscid  $\text{C}_6\text{H}_4\text{SiO}_2\text{H}$ , which is converted at 200° into the solid anhydride  $(\text{C}_6\text{H}_4\text{SiO})_2\text{O}$ , which is not melted at 200°.

Tetra-benzyl-silicane v. vol. i. p. 502.

Silicon tetra-phenyl-tetra-amide  $\text{Si}(\text{NHPh})_4$ . [138°]. Formed from  $\text{SiBr}_4$  and excess of aniline diluted with benzene, the product being distilled in a current of H at 105° (Reynolds, C. J. 55, 477). Colourless monoclinic crystals;  $a:b:c = .985:1:1.043$ ;  $\beta = 110^\circ 20'$ . V. sol. benzene, sol.  $\text{CS}_2$ , insol. ligroin. Decomposed by water and alcohol. Not decomposed by heating at 210°. HCl forms  $\text{SiCl}_4$  and aniline.

Silicon di-chloro-di-phenyl-di-amide  $\text{SiCl}_2(\text{NHPh})_2$ . Formed from  $\text{SiCl}_4$  and aniline (Harden, C. J. 51, 40). Amorphous solid. Decomposed by water into aniline hydrochloride and silica.

Silicon tetra-o-tolyl-tetra-amide  $\text{Si}(\text{NHC}_6\text{H}_4)_4$ . Formed from  $\text{SiCl}_4$ , o-toluidine, and benzene (Reynolds). Prisms, v. sol. benzene and  $\text{CS}_2$ . The compound  $\text{SiCl}_2(\text{NHC}_6\text{H}_4)_2$ , which is also formed from  $\text{SiCl}_4$  and o-toluidine, is a white granular powder (Harden).

Silicon tetra-p-tolyl-tetra-amide  $\text{Si}(\text{NHC}_6\text{H}_4)_4$ . [132°]. Formed from  $\text{SiCl}_4$  and p-toluidine in benzene (Reynolds). Botryoidal aggregate of needles, v. sol. benzene and ether, decomposed by water and alcohol.

Silicon tetra-naphthyl-tetra-amide  $\text{Si}(\text{NHC}_{10}\text{H}_7)_4$ . Formed from (β)-naphthylamine and  $\text{SiCl}_4$  (It.). Nodules, decomposed by water. Sl. sol. ligroin, sol. benzene.

SILICO-NITRATES.  $\text{SiO}_2$  seems to form some compounds with  $\text{N}_2\text{O}$ , and basic oxides: the salt  $3\text{SiO}_2 \cdot \text{N}_2\text{O}_5 \cdot 7\text{Ag}_2\text{O}$  ( $= 3\text{Ag}_2\text{SiO}_3 \cdot 2\text{AgNO}_3$ ) was obtained, in ruby-coloured prisms, by Rousseau a. Tite (C. R. 114, 294), by heating  $\text{AgNO}_3$  with a little water and fragments of marble in a sealed tube at 180°-300° for several hours; heated to dull redness, it gave off N oxides, and Ag and  $\text{Ag}_2\text{SiO}_3$  remained.

M. M. P. M.

SILICO-OXALIC ACID  $\text{H}_2\text{SiO}_4$ . -  $\text{O}:\text{Si}:\text{OH}$   
-  $\text{O}:\text{Si}:\text{OH}$

This compound is obtained, as a white amorphous powder, by the interaction of water and  $\text{SiCl}_4$  or  $\text{SiI}_4$  at 0°; the gelatinous pp. is washed with ice-cold water, dried *in vacuo* and then at 100° (Friedel a. Ladenburg, A. 203, 118). It is also produced by the interaction of  $\text{SiI}_4$  with

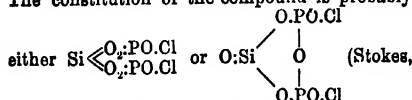

absolute alcohol. The compound is decomposed even by weak bases, with evolution of H.

M. M. P. M.

**SILICO-PHOSPHORIC OXIDES.** (*Silicophosphoric acids*.)  $\text{SiO}_2 \cdot \text{P}_2\text{O}_5$  and  $\text{SiO}_2 \cdot 2\text{P}_2\text{O}_5 \cdot 4\text{H}_2\text{O}$ . The compound  $\text{SiO}_2 \cdot \text{P}_2\text{O}_5 = \text{SiP}_2\text{O}_7$  is formed by dropping  $\text{SiO}_2$  prepared by decomposing  $\text{SiF}_4$  by water and drying the pp., into molten  $\text{HPO}_3$ , and washing with water (Hautefeuille a. Margottet, *C. R.* 96, 1052; v. also Skey, *C. N.* 16, 187). Large, hard, transparent crystals; S.G. 3.1 at  $14^\circ$ ; melts when strongly heated to a glass-like mass. The crystals are polymorphous; they are hexagonal under  $300^\circ$ ; at c.  $300^\circ$  they form leaflets resembling *tridymite*, between  $700^\circ$  and  $800^\circ$  they are regular octahedra, and between  $800^\circ$  and  $1000^\circ$  they assume the form of clinorhombic prisms. Water attacks the hexagonal, but not the octahedral or prismatic, crystals. Molten  $\text{AgNO}_3$  forms  $\text{Ag}_3\text{PO}_4$  and  $\text{SiO}_2$  with all the forms (H. a. M., *C. R.* 99, 789).

The compound  $\text{SiO}_2 \cdot 2\text{P}_2\text{O}_5 \cdot 4\text{H}_2\text{O}$  was obtained (H. a. M., *C. R.* 104, 56) by one-fourth saturating  $\text{H}_3\text{PO}_4$  aq with  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ , heating the solution in a Pt dish to  $125^\circ$  for 7-8 hours, and drying the solid which separated. The compound is a crystalline powder; decomposed by moist air; sol. water at  $0^\circ$ , but decomposed by water at the ordinary temperature to  $\text{H}_3\text{PO}_4$  aq and gelatinous  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ . M. M. P. M.

**SILICOPHOSPHORIC OXYCHLORIDE**  $\text{SiP}_2\text{O}_7\text{OCl}_2$  (*Silicopyrophosphoryl chloride*.) Prepared by heating  $\text{SiCl}_4 \cdot \text{OEt}$ , or  $\text{Si}(\text{OEt})_4$ , with excess of  $\text{POCl}_3$  to  $180^\circ$  for 2 hours, distilling off  $\text{EtCl}$ , and  $\text{SiCl}_4$  if prepared from  $\text{SiCl}_4 \cdot \text{OEt}$ , and heating the solid that remains to  $150^\circ$ - $200^\circ$  in a stream of dry air to remove adhering  $\text{POCl}_3$ . A white, loose, very hygroscopic, amorphous powder. Very sol. water, but with separation of  $\text{SiO}_2 \cdot x\text{H}_2\text{O}$ ; easily sol. alcohol, insol. ether. Decomposed very slowly below  $200^\circ$ , more rapidly above  $200^\circ$ , giving off  $\text{POCl}_3$ ; at a red heat  $\text{P}_2\text{O}_5$  comes off, and a glassy mass remains, probably consisting of  $\text{SiO}_2$  and  $\text{SiO}_2 \cdot \text{P}_2\text{O}_5$ . Addition of excess  $\text{AgNO}_3$  aq to solution in water (with a little alcohol to prevent separation of silica), followed by  $\text{HNO}_3$  aq, ppt.  $\text{AgCl}$ , and on filtering this off and adding  $\text{NH}_3$  aq drop by drop  $\text{Ag}_3\text{P}_2\text{O}_7$  is pptd. mixed with some  $\text{Ag}_3\text{PO}_4$ . Heated to  $100^\circ$  with  $\text{PCl}_5$  the equation  $\text{SiP}_2\text{O}_7\text{OCl}_2 + 4\text{PCl}_5 = \text{SiCl}_4 + 6\text{POCl}_3$  is realised. The constitution of the compound is probably

*Bulletin U.S. Geol. Survey*, No. 90 [1892] 47; also in *B.* 24, 933). M. M. P. M.

**SILICOTITANATES.** Compounds of silicates and titanates are found in certain minerals; *sphene*, for instance ( $\text{CaO} \cdot 3\text{SiO}_2 \cdot 2\text{CaTiO}_3$ ), may be called a silicotitanate. M. M. P. M.

**SILICOTUNGSTATES.** Compounds containing  $\text{SiO}_2$ ,  $\text{WO}_3$ , and basic radicles; v. **TUNGSTO-SILICATES**.

**SILICOVANADATES v. VANADO-SILICATES.**

**SILK v. PROTEINS.**

**SILVER.** Ag. At. w. 107.66. Mol. w. not known (v. *infra*, *Properties*). Melts at c.  $950^\circ$ ;

Person (*A. Ch.* [8] 27, 250) gave  $1000^\circ$ , Daniell (*T.* 1830, 237)  $1024^\circ$ , Violle (*C. R.* 85, 543)  $954^\circ$ , Becquerel (*J.* 1863.)  $916^\circ$ , Deville (*B.* 12, 791)  $916^\circ$ . B.p. not known; Meyer (*B.* 12, 1423) says that Ag does not appreciably evaporate at c.  $1570^\circ$ . S.G. c. 10.5; Playfair a. Joule (*C. S. Mem.* 3, 66) gave 10.53, and 9.13 to 9.28 for molten Ag, Dumas (*C. N.* 37, 82) gave 10.512 for Ag heated *in vacuo*, Roberts-Austen gave 10.57, and 9.46 to 9.5 for liquid Ag (*Pr.* 23, 495); for further data v. Clarke's *Table of Specific Gravities* [new ed.] 14. S.H.  $0^\circ$ - $100^\circ = .0557$  (Dulong a. Petit, *A. Ch.* [2] 7, 113); .0559 (Bunsen, *P.* 141, 1); .05722 (Lougouine, *A. Ch.* [5] 27, 398). C.E. .00002 between  $0^\circ$  and  $100^\circ$  (v. Matthiessen, *P.* 130, 50; Pizeau, *C. R.* 68, 1125); .00003721 from  $0^\circ$  to the m.p. (Roberts-Austen, *Pr.* 23, 495). T.C. 100 (that of copper = 73.6, and of Au = 53.2, Wiedemann a. Franz, *A.* 88, 191); heat sufficient to raise 109.6 mgm. water from  $0^\circ$  to  $1^\circ$  passes in i second through each sq. mm. of a plate of Ag 1 mm. thick, the two sides of which differ in temperature by  $1^\circ$  (Weber, *B. B.* 1880, 467). E.C. (Hg at  $0^\circ = 1$ ) 57.226 for soft Ag, 63.845 for hard Ag (Siemens, *P.* 110, 1); 62.12 (Benoit, *C. R.* 76, 382). H.C.  $[\text{Ag}^2\text{O}] = 5.900$  (*Th.* 3, 381). Heat of fusion (for 108 g.) 2.275 (Person, *A. Ch.* [3] 24, 275); 2.67 (Pionchon, *A. Ch.* [6] 11, 100). S.V.S. c.  $10.3$ . Emission spectrum gives a line 5464 in the yellow, 5209.9 in the green, and many lines in the orange, green, blue and violet (v. B. A. 1884, 412); for absorption-spectrum of Ag vapour v. Lockyer a. Roberts-Austen (*Pr.* 23, 344). Refraction equiv.

$$= \frac{n-1}{d}. \text{ At. w.} = 12.62 \text{ (Kanonnikoff, } J. R. 1884,$$

[1] 119); 13.2 (Gladstone, *Pr.* 18, 49).

**Occurrence.**—Found native, generally alloyed with Au, Cu, &c. The chief compounds found in ores are  $\text{Ag}_2\text{S}$  (frequently in combination with  $\text{Cu}_2\text{S}$ ,  $\text{Fe}_2\text{S}_3$ ,  $\text{Sb}_2\text{S}_3$ ,  $\text{As}_2\text{S}_3$ ,  $\text{Bi}_2\text{S}_3$ ,  $\text{PbS}$ , &c.),  $\text{AgCl}$ ,  $\text{AgBr}$ ,  $\text{AgI}$ , compounds of Ag with Se, Te, As, Sb, Bi, &c. Ag is also found in small quantities in most lead ores. According to Malaguti (*J. pr.* 42, 422; cf. Field, *D. P. J.* 143, 397), traces of salts of Ag (c. 1 mgm. Ag in 100 litres) are found in sea-water. Small quantities of Ag, probably as  $\text{AgCl}$ , have been found in volcanic dust (Mallet, *Pr.* 47, 277). Silver has been known and used from the earliest times (for a full historical account of silver, including the derivation of the name, v. SILVER in *Ladenburg's Handwörterbuch der Chemie*, 10, 635).

**Formation.**—1. By heating  $\text{Ag}_2\text{S}$  with PbO or  $\text{PbSO}_4$ , SO, and a compound or alloy of Ag and Pb are formed; the Pb may be separated from this alloy by cupellation.—2. By shaking  $\text{AgCl}$  with Hg and water,  $\text{HgCl}$  and an amalgam of Ag and Hg are formed; Ag remains when the Hg is removed from this amalgam by heating.—3. Ag is pptd. from solutions of its salts by Zn, Cu, Fe, &c.—4.  $\text{AgCl}$  is reduced to Ag by treatment with many reducing agents, such as Zn and  $\text{H}_2\text{SO}_4$  aq, also by fusion with  $\text{Na}_2\text{CO}_3$  and C.—5. Most easily-oxidised metals ppt. Ag from solutions of its salts. For an account of the extraction of Ag from its ores v. **DICTIONARY OF APPLIED CHEMISTRY**, vol. iii. p. 886.

**Preparation.**—Silver coins are dissolved in

pure dilute boiling  $\text{HNO}_3\text{Aq}$ , the solution is evaporated to dryness, the residue is heated till it melts, after cooling it is dissolved in  $\text{NH}_3\text{Aq}$ , after standing forty-eight hours the liquid is passed through a filter made of specially good paper, and the filtrate is diluted till it contains not more than 2 p.c. of Ag. This ammoniacal solution contains  $\text{AgNO}_3$  and  $\text{Cu}(\text{NO}_3)_2$ ; the whole of the Ag is pptd. by ammoniacal solution of  $(\text{NH}_4)_2\text{SO}_4$  at  $60^\circ$ . A solution of  $(\text{NH}_4)_2\text{SO}_4$  is prepared by saturating pure  $\text{NH}_3\text{Aq}$  with  $\text{SO}_2$  (made by heating pure Cu with pure  $\text{H}_2\text{SO}_4$ , diluted with  $\frac{1}{2}$  to  $\frac{2}{3}$  its volume of water); a measured quantity of this solution is mixed with excess of pure  $\text{NH}_3\text{Aq}$ , heated to boiling, and the ammoniacal solution containing  $\text{AgNO}_3$  and  $\text{Cu}(\text{NO}_3)_2$  is run from a burette into the boiling liquid until there is the faintest trace of blue colour in the liquid above the pptd. Ag. Cuprous sulphite is formed, and this reduces the  $\text{AgNO}_3$  in the ammoniacal liquid; when all the  $\text{AgNO}_3$  is reduced, the blue colour of the ammoniacal copper nitrate appears. The whole of the ammoniacal solution of  $\text{AgNO}_3$  and  $\text{Cu}(\text{NO}_3)_2$  is now mixed with the proper quantity of ammoniacal  $(\text{NH}_4)_2\text{SO}_4\text{Aq}$  required for complete reduction of the  $\text{AgNO}_3$ , the mixed liquids are set aside in a closed vessel for forty-eight hours, when c.  $\frac{1}{3}$  of the Ag is pptd.; the blue liquid is decanted off and heated on a water-bath to  $60^\circ$ – $70^\circ$ , whereby the whole of the Ag in solution is pptd. The two quantities of pptd. Ag are washed with ammoniacal water, by decantation, until the washings show no trace of blue colour on standing (or until  $\text{BaCl}_2\text{Aq}$  gives no trace of ppt.), the Ag is kept in contact with conc.  $\text{NH}_3\text{Aq}$  for some days, and is then washed with water until every trace of  $\text{NH}_3$  is removed. If it is desired to have the Ag in bars, the finely-divided metal obtained by pptn. is mixed with 5 p.c. of its weight of pure borax which has been strongly heated, and 5 p.c. pure  $\text{NaNO}_3$ , fused in a porcelain crucible and poured into kaolin moulds lined with a paste made of a mixture of kaolin that has been strongly heated and unignited kaolin; when cold the bars are cleaned with fine sand, then strongly heated with pure  $\text{KOH}\text{Aq}$  (to remove traces of kaolin) and washed with water. The bars may be cut with a chisel of very hard steel; if this is done the pieces must be warmed for some time with pure conc.  $\text{HCl}\text{Aq}$ , washed with  $\text{NH}_3\text{Aq}$ , and then with water (*Stas. Rech.* 88 *et seq.*). The Ag may be freed from traces of absorbed gases by distilling it; this is done by placing the Ag in a hole in a block of strongly-heated marble; this hole communicates, by a slit in the marble, with another hole from which an opening passes upwards to the surface of the marble; another opening admits the nozzle of an O-H blowpipe, so that the flame plays on the surface of the Ag. (For details v. *Stas, l.c.*) Dumas (*A. Ch.* [5] 15, 289) found that 1 kilo. of Ag considered pure gave from 59 to 174 c.c. O when heated in a Sprengel vacuum; it was supposed by some chemists (v. *Mallet, Z.* 1880. 1003; *Clarke, Recalculations of the Atomic Weights*, 262) that this result proved that Ag made by Stas' process was not quite pure; but Brauner has proved experimentally (*C. J.* 55, 899) that Ag prepared

Vol. IV.

by Stas' method described above, and distilled by the O-H flame in a block of burnt marble, gives off no O when heated *in vacuo* (v. also *Stas, Bull. Acad. roy. Belg.* [9] 18, 23; abstract in *C. J.* 58, 561).

*Properties.*—A white, very lustrous metal. Crystallises in forms in the regular system, chiefly cubes, octahedra, and rhombododecahedra; these crystals are obtained by slowly cooling molten Ag, or by the electrolytic deposition of the metal; they are also sometimes found native. Finely divided Ag—as obtained, for instance, by reduction of  $\text{AgCl}$ —is a grey powder, which becomes white and lustrous when compressed with a flat iron. A thin deposit of Ag on glass transmits bluish light.

Ag is harder than Au and softer than Cu. Ag reflects light and heat strongly; its absorptive power is very small. It is very malleable; Ag foil has been obtained .003 mm. thick. Ag is very ductile; .06 gram may be drawn to a wire 130 metres long; it is so tenacious that a cold-drawn wire of 2 mm. diameter does not break till it is loaded with 80–85 kilos (*Baudrimont, A. Ch.* [3] 30, 304). Ag is slightly volatile at a low-red heat *in vacuo*, but not at the ordinary pressure at this temperature, nor *in vacuo* at  $440^\circ$ – $450^\circ$  (*Stas, Bull. Acad. roy. Belg.* [3] 18, 23). It may be distilled, by heating, by the O-H flame, Ag placed in a block of burnt marble. Stas distilled 50 g. Ag in c. 15 mins.; part of the Ag appeared as a blue vapour during the distillation. When an alloy of Ag with a more volatile metal, such as Hg, Pb, or Sn, is heated, part of the Ag volatilises with the other metal. Molten pure Ag absorbs c. 20 times its volume of O from the air (v. *Lucas, A. Ch.* [2] 12, 402; *Gay-Lussac, A. Ch.* [2] 45, 221; *Graham, P. M.* [4] 32, 503; *Neumann, M.* 13, 40; *Levol, J. pr.* 57, 192); as the Ag cools it 'spits' and gives off the O it has absorbed; Dumas' experiments (*A. Ch.* [5] 15, 289) show that a little O is retained, but Brauner (*C. J.* 55, 899) has proved that no O remains if the Ag is distilled in a block of burnt marble. (For the chemical action of O on Ag v. *Reactions*, No. 1.) Pure Ag suffers no change when heated in air, H, or CO (van der Plaats, *Mundblad voor Natuurwetenschappen*, 1886. No. 2). Molten Ag absorbs P, but the whole of the P, except c. .002 p.c., separates on cooling (*Warren, C. N.* 56, 113).

The at. wt. of Ag has been determined (1) by finding the ratio of Ag to Cl in  $\text{AgCl}$  (*Berzelius, P.* 8, 17 [1826]; *Turner, T.* 1829. 297 [1829]; *Marignac, A.* 44, 23 [1842]; *ibid. Bibl. univ. Genève*, 46, 354 [1843]; *Mauméné, A. Ch.* [3] 13, 41 [1846]; *Dumas, A. Ch.* [3] 55, 134 [1859]; *Stas, Stas. Rech.* 38 *et seq.* [1860]); (2) by finding the ratio of Ag to Br in  $\text{AgBr}$ , and of Ag to I in  $\text{AgI}$  (*Marignac, l.c.* 46, 360 [1843]; *Stas, Stas. Nouv. R.* 158 *et seq.* [1865]); (3) by determining the ratio of Ag to  $\text{Ag}_2\text{S}$  formed therefrom (*Dumas, A. Ch.* [3] 55, 147 [1859]; *Stas, Stas. Rech.* 53 [1860]); (4) by reducing  $\text{Ag}_2\text{SO}_4$  to Ag (*Struve, A.* 80, 203 [1851]; *Stas, Stas. Rech.* 125 [1860]); (5) by converting  $\text{Ag}_2\text{SeO}_4$  into Ag (*Petterson, A. Ekman, Bl.* [2] 27, 205 [1876]); (6) by converting Ag into  $\text{AgNO}_3$  (*Marignac, A.* 59, 289 [1843]; *Stas, Stas. Rech.* 50 *et seq.* [1860]); (7) by determining

H H

S.H. of Ag; (5) by finding V.D. of AgCl at white heat (Biltz a. Meyer, *B.* 22, 725). The classical work of Stas has placed the value for the at. wt. on a very sure foundation.

Ramsay (*C. J.* 55, 521) measured the depression of the vapour-pressure of Hg by dissolving Ag therein; assuming that the mol. w. of liquid Hg is 200, and that equal volumes of dilute solutions of metals in Hg contain equal numbers of molecules, the results led to the conclusion that the mol. w. of Ag is the same as the at. wt.

AgCl is the only compound of Ag the vapour-density of which has been determined; the value found shows that the atom of Ag is monovalent in the gaseous molecule AgCl.

Ag is fairly closely related chemically to Cu and Au (v. COPPER GROUP OF ELEMENTS, vol. ii. p. 250).

*Allotropic forms of silver.* According to Schneider (*B.* 25, 1281, 1440), an aqueous solution of Ag, containing c. 20 g. Ag per litre, is obtained by mixing 150 g. FeSO<sub>4</sub>·7aq in 500 c.c. water and 280 g. Na citrate in 700 c.c. water, pouring the mixture into 500 c.c. of 10 p.c. AgNO<sub>3</sub>aq (it is best to divide the mixture into five parts, as small quantities are more easily dealt with), removing liquid from ppd. Ag after half an hour (by a pipette), filtering through a good filter under decreased pressure, and dissolving the ppd. Ag in as little water as possible; by adding absolute alcohol, and filtering, after some days, with help of a good water-pump, colloidal Ag containing from .3 to .5 p.c. of Fe salts is obtained. A very little HCl aq ppt. Ag with a little AgCl and AgCl (?) from solution of colloidal Ag. Carey Lea has carried out a series of researches on the properties of Ag ppd. from solutions of its salts by ferrous citrate, ferrous tartrate, and dextrin in presence of alkali (*Am. S.* [3] 37, 476; 38, 47, 129, 237; 41, 179, 259; *P. M.* [5] 31, 238, 320, 497; 32, 337). The pps. of Ag show almost every shade of colour, such as blue, red, green, purple, golden; some of the pps. are soluble in water, and some are not; most of the pps. are very sensitive to light, but they vary much in this respect; some of the pps. yield ordinary Ag when heated; ordinary Ag is also ppd. from solutions of soluble colloidal Ag by a little very dilute HCl aq. In no case does any so called allotropic Ag seem to have been obtained quite free from organic compounds; the percentage of Ag in the pps. varied from c. 90 to c. 98. For accounts of the properties of the various coloured pps. the memoirs of Carey Lea must be consulted; v. also Schneider, *B.* 24, 3370; Barus a. Schneider, *Z. P. C.* 8, 278; Prange, *R. T. C.* 9, 121; Muthmann, *P.* 20, 983. B. a. S. determined many of the physical properties of a solution of colloidal Ag, and concluded that the colloidal variety consists of extremely minute particles of ordinary Ag that remain suspended in the liquid for a considerable time.

*Reactions and Combinations.*—1. According to Debray (*C. R.* 66, 735), Ag is partially oxidised by very strongly heating in the O-H flame, using excess of oxygen. According to Le Chatelier (*Bl.* [2] 48, 342) pure ppd. Ag is oxidised by heating in oxygen at 300° under 15 atmos. pressure; after 50 p.c. of the Ag was

oxidised the change stopped.—2. *Ozonised oxygen* acts on moist, finely-divided Ag at the ordinary temperature, forming a peroxide (v. SILVER PEROXIDE, p. 471).—3. Ag combines easily with chlorine, bromine, iodine, and sulphur (v. SILVER CHLORIDE &c.); also, by heating, with selenium, arsenic, and phosphorus (v. SILVER SELENIDE &c.).—4. Finely-divided Ag is said to dissolve, with oxidation, in ammonia solution in presence of air (Carey Lea, *Zeit. für anorg. Chem.* 3, 180).—5. Ag reacts with steam at a white heat, absorbing O while H is given off.—6. Finely-divided Ag is oxidised by hydrogen peroxide (Berthelot, *A. Ch.* [5] 21, 164).—7. Finely-divided Ag is said to be oxidised by heating with oxides and salts that readily give up oxygen—e.g. MnO<sub>2</sub>, PbO<sub>2</sub>, Pb(NO<sub>3</sub>)<sub>2</sub>, &c.—8. Hydrogen sulphide forms Ag<sub>2</sub>S. Alkali sulphides also produce Ag<sub>2</sub>S.—9. Molten sodium chloride forms AgCl, some Na vapour being given off; solution of sodium chloride, as also of potassium or ammonium chloride, dissolves some Ag as AgCl.—10. Potassium iodide solution, in air, forms soluble AgI.KI.—11. Hot solution of potassium cyanide dissolves Ag, forming AgK(CN)<sub>2</sub> (v. Christomanos, *Fr.* 7, 301).—12. Fusion with silicates, such as glass, forms Ag<sub>2</sub>O, which dissolves in the molten silicate.—13. Ag dissolves in solution of ferrous sulphate on warming; as the solution cools the Ag<sub>2</sub>SO<sub>4</sub> is again decomposed, with formation of Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> and ppn. of finely-divided Ag.—14. A compound of Ag and Si is said to be formed by strongly heating Ag with potassium silicofluoride and potassium (Warren, *C. N.* 60, 5).—15. Ag dissolves in moderately dilute nitric acid, forming AgNO<sub>3</sub>, and giving off N oxides; the gaseous products are N<sub>2</sub>O and NO, according to Montemartini (*G.* 22, 384, 397, 426).—16. Conc. hydrobromic and hydriodic acids dissolve Ag on warming, with evolution of H; the dissolved AgBr or AgI is ppd. on dilution.—17. Hot conc. sulphuric acid dissolves Ag, giving off SO<sub>2</sub>; if a little Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> solution is added the Ag goes into solution without heating. Very finely-divided Ag, obtained by reduction of Ag salts by milk-sugar and alkali, is dissolved by very dilute H<sub>2</sub>SO<sub>4</sub>aq (Carey Lea, *Zeit. für anorg. Chem.* 3, 180). Friedheim (*B.* 19, 2554; 20, 307) says that Ag dissolves in dilute H<sub>2</sub>SO<sub>4</sub>aq containing KMnO<sub>4</sub>aq.—18. Chromic acid (i.e. solution of CrO<sub>3</sub> in water) produces red Ag<sub>2</sub>CrO<sub>4</sub>; HNO<sub>3</sub>aq, S.G. 1.2, in which K<sub>2</sub>CrO<sub>4</sub> is dissolved, gives a red deposit on the surface of Ag; this test is used to distinguish Ag from other white metals, such as Sn.—19. Ag in pieces is scarcely acted on by hydrochloric acid, even when hot and conc.; very finely-divided Ag is said to form a little AgCl, with evolution of H. Hydrofluoric acid is without reaction.—20. Ag is not acted on by molten alkalis or alkaline carbonates; hence KOH, &c., may be fused in dishes of Ag.—21. Ag alloys with many metals (v. SILVER, ALLOYS OF).

*Silver, alloys of.* Ag forms alloys with many metals. They are generally formed by heating the metals together; in a few cases—e.g. alloy with Ba or Mn—they are formed by heating Ag with metallic oxides and C.

*With aluminium.* An alloy of 100 parts Al with 5 parts Ag is harder and more easily

polished than Al, but otherwise has most of the properties of Al; it is used for making the pans, &c., of balances. Hirzel (*J.* 1858, 137) obtained alloys corresponding in composition with the formulæ  $\text{Ag}_3\text{Al}$ ,  $\text{Ag}_2\text{Al}$ , and  $\text{AgAl}$  (v. also Tissier, *C. R.* 43, 885; 52, 931; Debray, *C. R.* 43, 925).

With antimony, and with arsenic; v. SILVER ANTIMONIDE and ARSENIDE, *infra*.

With copper. Ag becomes harder, more elastic, more capable of being polished, and more slowly worn away when alloyed with Cu without losing much in malleability and ductility. Alloys with less than 50 p.c. Cu are white, with more than 50 p.c. Cu the colour becomes reddish. The S.G. of a Ag-Cu alloy is rather smaller than the mean of those of the constituent elements (v. Karmarsch, *D. P. J.* 108, 278). The composition of these alloys is rarely identical throughout a mass (v. Levot, *A. Ch.* [3] 36, 193). Alloys of Ag and Cu are used for making silver vessels and ornaments, and for coinage; the standard silver coinage alloy of the United Kingdom contains 925 parts Ag and 75 parts Cu per 1,000.

With mercury. The amalgams of Ag are formed (1) by the action of Hg on  $\text{AgNO}_3\text{Aq}$ , (2) by the action of finely-divided Ag on  $\text{HgCl}_2\text{Aq}$ , (3) by dissolving Ag in Hg. The compositions of many of these amalgams can be represented by formulæ, but it is very doubtful whether any of them are definite compounds. For accounts of these amalgams v. Campani, *J.* 1870, 373; Joule, *C. J.* [2] 1, 378; Crookevitt, *J.* 1847-48, 393; Malaguti a. Durocher, *Ann. M.* 17, 336; Gay-Lussac, *A. Ch.* 53, 218.

Alloys of Ag with the following metals have been described:—Ba (Clarke, *G. A.* 62, 373; Lampadius, *S.* 15, 146); Cd (Wood, *C. N.* 6, 135); Au (G. Rose, *P.* 23, 181; Levot, *A. Ch.* [3] 15, 55; 27, 310); Ir; Fe; Pb (Levot, *A. Ch.* [3] 39, 173); Mg; Mo; Ni; Pd (Graham, *J.* 1868, 144); Pt; K; Rh; Na; Sn; Zn (v. Wright a. Thompson, *Pr.* 48, 25).

Silver, antimonide of. The mineral *dykstrite* has approximately the composition  $\text{Ag}_3\text{Sb}$ ; when heated to dull redness in H, the compound  $\text{Ag}_3\text{Sb}$  is said to remain (von Bonsdorff, *S.* 34, 225). The compound  $\text{Ag}_3\text{Sb}$  is also obtained by ppg.  $\text{AgNO}_3\text{Aq}$  by Sb hydride; using conc.  $\text{AgNO}_3\text{Aq}$  the compound  $\text{Ag}_3\text{Sb} \cdot 3\text{AgNO}_3$  was formed (Polek a. Thümmel, *B.* 16, 2435).

Silver, arsenide of. No definite compound of Ag and As has been obtained. By heating Ag powder with As about 16 p.c. of As is absorbed by the Ag to form a grey, brittle solid (Gehlen). By passing As hydride into conc.  $\text{AgNO}_3\text{Aq}$  the compound  $\text{Ag}_3\text{As} \cdot 3\text{AgNO}_3$  was obtained (P. a. T., *loc.*).

Silver, bromide of,  $\text{AgBr}$ . (*Argentio bromide*.) Formula probably molecular, from analogy of  $\text{AgCl}$ . Occurs native in Chili and Mexico.

Preparation.— $\text{HBrAq}$  or alkali bromide solution is added to  $\text{AgNO}_3\text{Aq}$  till ppn. is complete; the pp. is washed with water in the dark and dried.

Properties.—A pale-yellow solid; melts at  $c. 434^\circ$  (Carnelley, *C. J.* 29, 489). S.G.  $6.245$  at  $0^\circ$ ,  $5.595$  at m.p. (Rodwell, *Pr.* 31, 291). S.H. ( $15^\circ$  to  $98^\circ$ )  $0.7391$  (Regnault, *A. Ch.* [3] 1, 129).

For effects of heat on  $\text{AgBr}$  v. Rodwell (*Pr.* 28, 280). Obtained in octahedra by crystallising from  $\text{HBrAq}$ . Solubility of  $\text{AgBr}$  dried at  $100^\circ$  in  $\text{NH}_4\text{Aq}$  S.G.  $0.986$ ,  $-0.051$  (Pohl, *J. pr.* 82, 52). Granular  $\text{AgBr}$  is slightly sol. water above  $50^\circ$ ; flocculent  $\text{AgBr}$  is slightly sol. water above  $38^\circ$  (Stas, *A. Ch.* [5] 3, 289). Sol. hot  $\text{Hg}(\text{NO}_3)_2\text{Aq}$ ;  $\text{AgBr}$  crystallises out on cooling (Debray, *C. R.* 70, 995). Sol. solutions of alkali bromides. H.F.  $[\text{Ag}, \text{Br}] = 22,700$  (*Th.* 3, 381). According to Berthelot (*Bl.* [2] 39, 19), the reaction  $[\text{Ag}, \text{Br}]$  has the value 23,700 when crystalline  $\text{AgBr}$  is formed, and the value 20,000 when the  $\text{AgBr}$  is amorphous (in both cases using liquid Br). B. also says that in the formation of  $\text{AgBr}$  by adding  $\text{KBrAq}$  to  $\text{AgNO}_3\text{Aq}$  20,700 cals. are produced, and that when  $\text{AgNO}_3\text{Aq}$  is added to  $\text{KBrAq}$  only 17,600 cals. are produced at first, but that temperature then rises until 20,600 cals. are evolved; B. thinks that two forms of  $\text{AgBr}$  are formed, one more stable than the other. Vogel (*B.* 16, 1160) distinguishes two modifications of  $\text{AgBr}$ , one ppd. from aqueous solutions and very sensitive to blue rays, the other ppd. from solutions in absolute alcohol and sensitive to the violet rays. Stas (*A. Ch.* [5] 3, 289) distinguishes six forms of  $\text{AgBr}$ :—(1) flocculent, white, by adding dilute alkali bromide solution to excess of cold  $\text{AgNO}_3\text{Aq}$ ; (2) flocculent, yellow, by using excess of bromides pptant; (3) powdery, white, by shaking (1) or (2) with water; (4) intense yellow, by heating (4); (5) granular, white-yellow, by pouring the flocculent or powdery variety, shaken with water, into boiling water, also by adding very dilute  $\text{NH}_4\text{BrAq}$  to boiling  $\text{AgNO}_3\text{Aq}$  (1:1000); (6) pure yellow, crystalline variety.

Reactions and Combinations. — 1.  $\text{AgBr}$  darkens rapidly when exposed to sunlight. Carey Lea says that the dark product of the action of light on  $\text{AgBr}$  reacts with  $\text{HNO}_3\text{Aq}$  to re-form  $\text{AgBr}$ , and Ag which dissolves in the acid (*Am. S.* [3] 15, 189). The action of light on the Ag haloids is treated more fully under *Silver chloride* (*q. v.*). — 2. Heated in chlorine,  $\text{AgCl}$  and Br are produced. — 3. Dissolves slowly in hot *silver nitrate* solution; the salt  $\text{AgBr} \cdot \text{AgNO}_3$  separates on cooling (Risse, *A.* 111, 43; Riche, *A.* 111, 39). — 4. Combines with silver chloride and iodide to form compounds  $\text{Ag}_2\text{Br}_2\text{I}_2\text{Cl}_2$  (v. SILVER IODOBROMOCHLORIDES, p. 470).

$\text{AgBr}$  resembles  $\text{AgCl}$  in most of its reactions;  $\text{NH}_3$  is not absorbed by dry  $\text{AgBr}$  (Rammelsberg, *P.* 55, 248).

Silver, bromo-iodochlorides of, v. SILVER IODOBROMOCHLORIDES (p. 470).

Silver, carbides of. Gay-Lussac noticed that Ag absorbed  $c. 3$  p.c. C when heated with lampblack (*A. Ch.* [2] 58, 222);  $\text{Ag}_2\text{C}$  requires 2.7 p.c. C. A yellow powder, approximately agreeing with the composition  $\text{Ag}_2\text{C}$ , was obtained by Gerhardt and Cahours (*A. Ch.* [3] 1, 76) by heating Ag cuminate; the same compound was probably produced by Liebig by heating  $\text{AgCN}$  (*A.* 38, 21). By heating an aqueous solution of Ag pyrotartrate, filtering from the brown pp. produced, and boiling the pp., Berzelius obtained a dark-brown, metal-like pp., probably  $\text{AgC}$  (*P.* 86, 28; cf. Regnault, *A.* 19, 153).

## SILVER CHLORIDES.

**Silver, chlorides of.** The isolation of a chloride of Ag containing less Cl than AgCl is not yet certain. Cl is given off when AgCl darkens in sunlight, but whether the darkened product is a chloride or an oxychloride is not finally determined (*v. Action of light on silver chloride, infra*).

**SILVER SUBCHLORIDE ? Ag<sub>2</sub>Cl.** (*Argentous chloride*.) According to Güntz (*C. R.* 112, 861), Ag<sub>2</sub>Cl is formed by passing dry HCl over Ag<sub>2</sub>I<sup>1</sup> (*v. SILVER SUBFLUORIDE*, p. 469) as long as darkening occurs and the solid continues to gain in weight. The compound is also said to be formed by passing vapour of CCl<sub>4</sub>, SiCl<sub>4</sub>, or PCl<sub>5</sub> over dry Ag<sub>2</sub>F. A subchloride is formed, according to von Bibra (*J. pr.* [2] 12, 55), by digesting with conc. HClAq the product of the reduction of Ag citrate by H at 100°; after drying, the black solid is said to have the composition Ag<sub>2</sub>Cl<sub>3</sub>, and with NH<sub>3</sub>Aq to give Ag and AgCl.3NH<sub>3</sub>. Newbury (*Am. S.* 8, 196) failed to obtain any subchloride by this method; he also found that the reduction of Ag citrate by H at 100° does not yield any definite compound, but probably a mixture of unchanged citrate and Ag.

**SILVER CHLORIDE AgCl.** (*Argent chloride*.) Mol. w. 143.03. V.D. 80 at c. 1700° (Biltz a. Meyer, *B.* 22, 725). Melts at 0°=5.505; at m.p.=4.919 (Rodwell, *Pr.* 31, 291). S.H. (13° to 98°) .09109 (Regnault, *A. Ch.* [3] 1, 129). For expansion of AgCl by heat *v. Rodwell* (*Pr.* 25, 280). H.F. [AgCl] = 22,700 (*Th.* 3, 381); 29,200 (Berthelot, *Bl.* [2] 39, 19). For solubilities in various liquids *v. Properties*.

**Occurrence.**—Native, as *hornsilver*, in Siberia, Mexico, Peru, the Harz, Alsace, &c.

**Preparation.**—1. By adding dilute HClAq, or solution of a chloride, to solution of any salt of Ag except Ag<sub>2</sub>S<sub>2</sub>O<sub>8</sub>, washing the white curdy pp., drying, and heating to incipient fusion. Obtained in octahedral crystals by dissolving in large quantity of conc. HClAq and evaporating.—2. By heating Ag to redness in a stream of Cl or HCl gas.—3. By fusing NaCl with finely-divided Ag, washing, and drying.—4. Very slowly by the action of HClAq on Ag in the presence of air.

**Properties.**—A white solid. According to Cooke (*Am. S.* [3] 21, 220) AgCl is very slightly sol. cold water, and very distinctly sol. boiling water; he found that 1.4561 g. AgCl washed with 60 litres boiling water lost .2241 g.=15.39 p.c.; the solvent action was entirely prevented by the addition of .05 g. AgNO<sub>3</sub> per litre of water. Stas (*C. R.* 73, 998) distinguished four forms of AgCl: (1) gelatinous; (2) curdy, flocculent; (3) powdery; (4) granular, crystalline, or fused. The curdy, flocculent form is the most sol. in water; it is formed by ppg. cold dilute AgNO<sub>3</sub>Aq by a chloride solution; on shaking it changes to the less sol. powdery variety. The granular, crystalline, or fused form is insol. cold water (10 million parts cold water dissolve 1 part) but it begins to dissolve at 30° (*cf. Berthelot, A. Ch.* [5] 29, 241, for the heats of solution in KCN<sub>2</sub>Aq of different preparations of AgCl). AgCl is sol. conc. HClAq and in saturated solutions of various metallic chlorides; Vogel (*C. C.* 5, 578) gives the following table:—

100 c.c. cold HClAq S.G. 1.166 dissolve	298	g. AgCl
" boiling	.560	" "
" conc. HClAq diluted with 1 pt. H <sub>2</sub> O	.066	" "
" conc. HClAq diluted with 2 pts. H <sub>2</sub> O	.018	" "
" conc. HClAq diluted with 3 pts. H <sub>2</sub> O	.0089	" "
" conc. HClAq diluted with 5 pts. H <sub>2</sub> O	.0085	" "
" saturated BaCl <sub>2</sub> Aq	.0143	" "
" " SrCl <sub>2</sub> Aq	.0684	" "
" " CaCl <sub>2</sub> Aq	.0930	" "
" " MgCl <sub>2</sub> Aq	.171	" "
" " NaClAq	.095	" "
" " KClAq	.0472	" "
" " NH <sub>4</sub> ClAq	.1875	" "

One part AgCl dissolves in 50,000 parts boiling conc. HNO<sub>3</sub>Aq (Thorpe, *C. N.* 25, 198). NH<sub>3</sub>Aq dissolves AgCl; 1 litre NH<sub>3</sub>Aq S.G. .924 dissolves 69.5 g. freshly ppd. AgCl, according to Millon and Comaille (*C. R.* 56, 309). AgCl crystallises from solutions in NH<sub>3</sub>Aq, on evaporation; explosive silver is obtained from boiling solutions (*v. SILVER NITRIDES*, p. 470). According to Terrell (*Bl.* [2] 51, 598), crystals of AgCl.2NH<sub>3</sub> separate from a hot solution of AgCl in NH<sub>3</sub>Aq; these crystals lose NH<sub>3</sub> in the air. AgCl dissolves easily in Na<sub>2</sub>S<sub>2</sub>O<sub>8</sub>Aq, forming Ag<sub>2</sub>Na<sub>2</sub>(S<sub>2</sub>O<sub>8</sub>)<sub>2</sub>Aq; AgCl also dissolves readily in KCN<sub>2</sub>Aq forming AgK(CN)<sub>2</sub>, and in NH<sub>4</sub>HSO<sub>4</sub>Aq forming double Ag-NH<sub>4</sub> sulphites (*v. Svensson, B.* 4, 714). A hot solution of AgNO<sub>3</sub>Aq dissolves AgCl; Risse says that a double compound of AgNO<sub>3</sub> and AgCl separates on cooling (*A.* 111, 39), but Debray asserts that simple solution occurs (*C. R.* 70, 995). Hg(NO<sub>3</sub>)<sub>2</sub>Aq also dissolves AgCl; Wackenroder (*A.* 91, 317) and Field (*J.* 1857, 255) say that AgCl separates on cooling a hot saturated solution; Stas (*A. Ch.* [5] 3, 180) found that a little AgNO<sub>3</sub> is formed.

**Reactions.**—1. AgCl is reduced to Ag by many metals, *e.g.* Zn or Fe, in presence of dilute acid; Cu reduces AgCl in presence of NH<sub>3</sub>Aq, with formation of Ag and CuO.H<sub>2</sub>O.—2. Heated in hydrogen, or with carbon, or with several organic compounds, AgCl is reduced to Ag.—3. Solution of hydropic acid forms AgI and HClAq.—4. Caustic alkali solutions produce Ag<sub>2</sub>O.

**Action of light on silver chloride.** AgCl darkens when exposed to sunlight in ordinary air. During the darkening Cl is given off (Scheele; von Bibra, *J. pr.* 122, 39; Hitchcock, *Am.* 11, 474; Béchamp, *Bl.* [3] 6, 836; Richardson, *C. J.* 59, 536; Baker, *C. J.* 61, 728). Only a small portion of the AgCl is changed to the dark compound (*v. R., l.c.*; B., *l.c.*, got .09 g. of the dark body from 51 g. AgCl). AgCl does not darken in thoroughly dried oxygen (B., *l.c.*; nor in dried air according to Carey Lea, *Zeit. für anorg. Chem.* 3, 184). AgCl does not darken *in vacuo*, when thoroughly dry (Abney; B., *l.c.*). Carey Lea (*l.c.*) found that AgCl darkened under dry petroleum; Baker noticed darkening under benzene in absence of air, and he showed that the dark substance was Ag. B. (*l.c.*) noticed darkening, with formation of Ag, under CCl<sub>4</sub>, but he proved that if the CCl<sub>4</sub> contained no trace of free Cl darkening did not occur. For the influence of HCl and chlorides in water upon the rate of darkening of AgCl in the water *v. Richardson (l.c.)*. The dark substance was supposed by some to be a subchloride, but Baker

has shown that it contains O (Hodgkinson had formerly arrived at this conclusion; v. Meldola's *Chemistry of Photography* [1889], p. 856). B. kept pure AgCl, dried at 150°, in sunshine, in a current of air freed from CO<sub>2</sub>, and dried by H<sub>2</sub>SO<sub>4</sub>, until it darkened; he measured the O obtained from the darkened product, by decomposing by Cl, and also determined the Ag and Cl; the results agreed approximately with the formula Ag<sub>2</sub>OCl; the atomic ratio of Ag to Cl found in various experiments was almost exactly 2:1, and of Ag to O was nearly 5:2; the darkened product dissolved in conc. KClAq, on dilution AgCl was ppd. and the solution had a slightly alkaline reaction, as would be expected if an oxychloride were present in the dark-coloured substance. B. also found that a little H<sub>2</sub>O was obtained by heating the dark substance in dry H<sub>2</sub>; Richardson (*C. J.* 59, 536) failed to obtain any water by treating darkened AgCl in this way; R. also failed to get O from the darkened AgCl by heating it to the m.p. in connection with a Sprengel pump. B. (*l.c.*) found that the dark-coloured product became white when left in the dark for some days, and that a small quantity of O was absorbed during this change; he, therefore, concludes that two oxychlorides of Ag are formed, one of which is dark-coloured and absorbs a little O to form another, white, oxychloride. Carey Lea (*Am. S.* [3] 38, 356) thinks that the darkening action of light on AgCl is preceded by the formation of what he calls a *photochloride*. The photochloride is supposed to contain less Cl than the normal chloride; and probably to be a compound of AgCl with a subchloride or oxychloride; it is extremely sensitive to the action of light, and undergoes many changes of colour when exposed to light (*Am. S.* [3] 33, 349, 480, 489; 34, 33; and full abstract in *C. J.* 54, 1). For the application of the effects of light on AgCl to photography v. PHOTOGRAPHIC CHEMISTRY, this vol. p. 154; and PHOTOGRAPHY, in DICTIONARY OF APPLIED CHEMISTRY, vol. iii.

**Combinations.**—1. With several *metallic chlorides*, especially the alkaline chlorides; generally forming compounds of the type AgCl.MCl. Wells and Wheeler (*Am. S.* [3] 44, 156) obtained the compound AgCl.2CsCl.—2. With *ammonia gas*. According to H. Rose (*P.* 20, 157), 2AgCl.3NH<sub>3</sub> is formed. Isambert (*C. R.* 64, 1259; v. also Horstmann, *B.* 9, 749) studied the vapour-pressures of the NH<sub>3</sub> given off, and concluded that two compounds are formed when NH<sub>3</sub> is absorbed by AgCl—viz. 2AgCl.3NH<sub>3</sub> and AgCl.3NH<sub>3</sub> (v. curves given in DISSOCIATION, vol. ii. p. 397). Bodländer (*Z. P. C.* 9, 730) measured the reduction of the freezing-point of water produced by the compound 2AgCl.3NH<sub>3</sub>; as this reduction was much larger than the normal, he concluded that the compound is dissociated in aqueous solution; a similar conclusion was come to by measuring the electrical conductivities of aqueous solutions. The dissociation cannot have been into NH<sub>3</sub> and AgCl, says B., else AgCl would have separated out; hence the dissociation must be electrolytic, and the solution must contain Ag and Cl as free ions. This conclusion was confirmed by finding that PbAc<sub>2</sub>Aq ppd. PbCl<sub>2</sub> from 2AgCl.3NH<sub>3</sub> in NH<sub>3</sub>Aq, KI Aq ppd. AgI, and (NH<sub>4</sub>)<sub>2</sub>SAq ppd. Ag<sub>2</sub>S; confirmatory evidence

was also found in the fact that addition of NH<sub>4</sub>Cl or AgNO<sub>3</sub> reduced the solubility in water of 2AgCl.3NH<sub>3</sub>, in keeping with the law regarding the effect on the solubility of an electrolyte of the presence of one of its ions. B. concludes that 2AgCl.3NH<sub>3</sub> is a definite compound, which is electrolytically dissociated in aqueous solution.—3. With *silver iodide and bromide*; v. SILVER IODOBROMOCHLORIDES, p. 470.

Silver, chloro-iodobromides of; v. SILVER IODOBROMOCHLORIDES, p. 470.

Silver, cyanide of; v. vol. ii. p. 346.

Silver, ferriocyanide of; v. vol. ii. p. 340.

Silver, ferrocyanide of; v. vol. ii. p. 337.

Silver, fluorides of. Two fluorides of Ag probably exist, Ag<sub>2</sub>F and AgF, although there is still some doubt as to the isolation of the first of these.

Silver subfluoride (? Ag<sub>2</sub>F). (*Argentous fluoride*.) By electrolysing saturated AgFAq, using Ag electrodes, and a current so strong that the liquid became hot, Güntz (*C. R.* 110, 1337) noticed the separation of brass-coloured crystalline plates at the negative pole (if a weaker current was used, Ag was deposited). Treatment of these crystals with water gave AgFAq and Ag, the ratio of Ag separating to Ag going into solution being practically unity; hence G. gives the formula Ag<sub>2</sub>F to the yellow crystals. G. says that the same compound is obtained by heating finely-divided Ag with AgFAq in a sealed tube to nearly 90°. Ag<sub>2</sub>F does not change in dry air; it decomposes slowly in moist air, and rapidly in water. Heated in dry HCl, CCl<sub>4</sub>, PCl<sub>5</sub>, &c., Ag<sub>2</sub>Cl is said to be formed (G., *C. R.* 112, 861).

Silver fluoride AgF. (*Argentous fluoride*.) Formula probably molecular, from analogy of AgCl. Prepared by dissolving Ag<sub>2</sub>CO<sub>3</sub> that has been freshly ppd. and well washed, in HF Aq, evaporating to dryness in a Pt dish, with constant stirring, dissolving the black residue in water, filtering, and evaporating *in vacuo* over H<sub>2</sub>SO<sub>4</sub> in the dark (Moissan, *Bl.* [3] 5, 456; cf. Güntz, *A. Ch.* [6] 3, 42). A yellow, transparent, elastic solid; sol. water; melts at c. 435° (M., *l.c.*). S.G. 5.852 at 15.5° (Gore, *Pr.* 18, 157). Fremy (*A. Ch.* [3] 47, 39) obtained large colourless prisms, to which he gave the formula AgF.2aq, by evaporating a solution of Ag<sub>2</sub>CO<sub>3</sub> or Ag<sub>2</sub>O in HF Aq; these crystals lost 2aq *in vacuo*, but some oxyfluoride was always formed (cf. Marignac, *Ann. M.* [5] 15, 270). Heated in air, AgF is decomposed, by the moisture present, to Ag<sub>2</sub>O and HF, according to Gore (*l.c.*). AgF interacts violently with POCl<sub>3</sub>, PCl<sub>5</sub>, SiCl<sub>4</sub>, and BCl<sub>3</sub>, giving AgCl and fluoride of P, Si, or B (Moissan, *l.c.*). Molten AgF attacks vessels of Ag or Pt. The dry salt is said to absorb c. 800 times its volume of NH<sub>3</sub> (Gore, *l.c.*). Heating with I produces AgI and IF<sub>3</sub> (Gore, *Pr.* 80, 70; where a few other reactions of compounds with AgF are given).

Silver, fulminating; v. SILVER NITRIDES, p. 470; *Silver fulminate* (q. v., vol. ii. p. 317) is sometimes called fulminating silver.

Silver, hydroxides of; v. SILVER OXIDES AND HYDRATED OXIDES, p. 470.

Silver, iodides of. The isolation of an iodide other than AgI is very doubtful.

**SILVER SUBIODIDE** (?  $\text{Ag}_2\text{I}$ ). Güntz (*C. R.* 112, 861) states that this compound is formed by the interaction of  $\text{HI}$  and  $\text{Ag}_2\text{F}$ ; but no analyses are given.

**SILVER IODIDE**  $\text{AgI}$ . (*Argentio iodide*.) Formula probably molecular, from analogy of  $\text{AgCl}$ . Melts at  $c. 530^\circ$  (Carnelley, *C. J.* 29, 489); at  $527^\circ$  (Rodwell, *Pr.* 25, 280). S.G. at  $0^\circ = 5.675$ , at  $527^\circ = 5.522$ ; maximum density at  $142^\circ$  (R., l.c.). V.D. said to be 214 (Dewar a. Scott, *B. A.* 1881, 597). S.H. ( $15^\circ$  to  $98^\circ$ ) .06159 (Regnault, *A. Ch.* [3] 1, 129; v. also Bellati a. Romanese, *Pr.* 34, 104). H.F. [ $\text{AgI}$ ] = 13,800 (*Th.* 3, 381); 14,300 for crystalline  $\text{AgI}$  (Berthelot, *Bl.* [2] 39, 18).

**Occurrence.**—As *iodite* in Peru, Mexico, the Harz, Spain, &c.; forms hexagonal tablets; also in combination with  $\text{AgBr}$  as *iodobromite* in small quantities in Nassau.

**Preparation.**—1. By adding  $\text{HIAg}$ , or solution of an iodide, to  $\text{AgNO}_3\text{Aq}$ , washing, and drying.—2. By the interaction of finely-divided  $\text{Ag}$  with  $\text{HIAg}$ ,  $\text{H}$  is evolved at ordinary temperatures and  $\text{AgI}$  formed; a solution saturated by heating  $\text{HIAg}$  with  $\text{Ag}$  deposits crystals of  $\text{AgI} \cdot x\text{HI}$  on cooling (v. *infra*, *Combinations*, No. 2), and the liquid decanted from these deposits hexagonal crystals of  $\text{AgI}$  on standing in air.—3. Crystals of  $\text{AgI}$  are also obtained by boiling saturated  $\text{AgNO}_3\text{Aq}$  with  $\text{HgL}$ , and allowing to cool (Field, *J.* 1857, 255).—4. The interaction of a mixture of  $\text{HClAq}$  and  $\text{HIAg}$  with  $\text{Ag}$  produces only  $\text{AgI}$ , according to Deville (*A.* 101, 197).

**Properties.**—As obtained by adding alkali iodide to excess of  $\text{AgNO}_3\text{Aq}$ ,  $\text{AgI}$  is a curly pp., yellow, with a slight orange tint; by adding  $\text{AgNO}_3\text{Aq}$  to excess of alkali iodide, a pure yellow, powdery pp. of  $\text{AgI}$  is formed; the former pp. is sensitive to light, the latter, after washing in the dark, is not discoloured by light.  $\text{AgI}$  melts to a yellow liquid, which becomes red and then dark-red as temperature rises; the liquid solidifies to a yellow, horny, crystalline mass. Rodwell (*Pr.* 25, 290) found that  $\text{AgI}$  contracted considerably at the moment of solidification; regular contraction then took place to  $142^\circ$ , whereat there was sudden and considerable expansion accompanied by change from the amorphous to the crystalline form; this was followed, as temperature fell, by slight expansion (for measurements v. R., l.c.).  $\text{AgI}$  exists in two forms: above  $142^\circ$  up to the m.p. it is yellow, transparent, and flexible; below  $142^\circ$  it is pale green, crystalline, opaque, and brittle (R., l.c.).  $\text{AgI}$  is nearly insol.  $\text{NH}_4\text{Aq}$ ; according to Martini (*S.* 56, 153) 1 part  $\text{AgI}$  requires 2560 parts  $\text{NH}_4\text{Aq}$ , S.G. .96, for solution.  $\text{AgI}$  dissolves in  $\text{Na}_2\text{S}_2\text{O}_3\text{Aq}$ , in  $\text{KCN Aq}$ , and in  $\text{NaCl Aq}$ ; it dissolves readily in hot  $\text{Hg}(\text{NO}_3)_2\text{Aq}$ , and crystallises therefrom on cooling (v. also *Combinations*).

**Reactions.**—1. Heated in *chlorine*,  $\text{AgCl}$  is formed.—2. Reduced by contact with *metals*, such as  $\text{Zn}$  or  $\text{Fe}$ , in presence of acids. Most of the reactions of  $\text{AgI}$  closely resemble those of  $\text{AgCl}$ .

**Combinations.**—1. Dry  $\text{AgI}$  absorbs *ammonia*; Rammelsberg (*P.* 48, 170) says that  $2\text{AgI} \cdot \text{NH}_3$  is formed (for dissociation-pressures of this compound v. Isambert, *C. R.* 64, 1259). By heating

$\text{AgI}$  with excess of  $\text{NH}_4\text{Aq}$  in a sealed tube at  $100^\circ$ , Terrell obtained crystals of  $\text{AgI} \cdot 2\text{NH}_3$  (*Bl.* [2] 41, 598).—2.  $\text{AgI}$  dissolves in hot conc. *hydriodic acid* solution; the liquid deposits large, colourless, unstable crystals of  $\text{AgI} \cdot \text{HI}$  (?) (Deville, *C. R.* 42, 896); Berthelot obtained transparent crystals of  $3\text{AgI} \cdot \text{HI} \cdot 7\text{H}_2\text{O}$  (*A. Ch.* [5] 23, 89).—3. According to Proust (*A.* 29, 828) a solution of  $\text{AgI}$  in a hot solution of *mercuric nitrate* deposits crystals of  $4\text{AgI} \cdot 2\text{Hg}(\text{NO}_3)_2 \cdot \text{aq}$  on cooling.—4.  $\text{AgI}$  dissolves in *silver nitrate* solution containing more than 3 p.c.  $\text{AgNO}_3$  (Vogel); water re-ppts.  $\text{AgI}$ . For accounts of different compounds obtained v. Kremers (*J. pr.* 71, 54), Stürenberg (*Ar. Ph.* [2] 143, 112), Weltzien (*A.* 95, 127), Riche (*A.* 111, 39), Riese (*A.* 111, 43).  $\text{AgI}$  also combines with *silver nitrate* and *lead nitrate*, and with *antimonide*, *arsenide*, *phosphide*, and *sulphide* of *silver* (v. Poleck a. Thümmel, *Ar. Ph.* [3] 22, 1).—5. With *alkali iodides* and *alkaline earth iodides* (v. Boullay, *A. Ch.* [2] 34, 377; Berthelot, *Bl.* [2] 39, 24; Johnson, *C. N.* 37, 110; Maxwell Simpson, *Pr.* 27, 120).

**Silver, iodobromochlorides of.** Rodwell (*Pr.* 25, 292) prepared various compounds of  $\text{AgI}$ ,  $\text{AgBr}$ , and  $\text{AgCl}$  by melting the constituents together. R. studied especially the effects of heat on the S.G., change of volume, and m.p. of these bodies. The formula  $x\text{AgI} \cdot y\text{AgBr} \cdot z\text{AgCl}$  expresses the composition of the compounds examined;  $x$  varied from 1 to 4,  $y$  was always 1, and  $z$  varied from 1 to 2.

**Silver, nitrides of.** Raschig (*A.* 233, 93) has shown that the explosive substance first prepared by Berthollet, by the action of conc. cold  $\text{NH}_4\text{Aq}$  on  $\text{Ag}_2\text{O}$ , and supposed by B. to be a compound of  $\text{Ag}_2\text{O}$  and  $\text{NH}_3$ , is a nitride of  $\text{Ag}$ ,  $\text{Ag}_3\text{N}$ , mixed with finely-divided  $\text{Ag}$ .  $\text{Ag}_3\text{N}$  is best prepared by allowing a conc. solution of  $\text{Ag}_2\text{O}$  in  $\text{NH}_4\text{Aq}$  to stand in air, or by adding alcohol.  $\text{Ag}_3\text{N}$  dissolves in  $\text{KCN Aq}$ , forming  $\text{AgCN}$ ,  $\text{KHOAg}$ , and  $\text{NH}_3$ .

The  $\text{Ag}$  salt of  $\text{HN}_3$  may be called *silver nitride*; v. *HYDRAZOIC ACID*, vol. iii, p. 559.

**Silver, nitroprusside of.** v. vol. ii, p. 341. **Silver, oxides and hydrated oxides of.** Only one oxide of  $\text{Ag}$  has been certainly isolated; the existence of any hydrated oxide is doubtful.

**SILVER OXIDE**  $\text{Ag}_2\text{O}$ . (*Argentio oxide*.) Mol. w. not known.

**Formation.**—1. By heating  $\text{Ag}$  much above the temperature of volatilisation in the  $\text{O-H}$  flame, using excess of  $\text{O}$  (Debray, *C. R.* 66, 735).—

2. By passing an electric current through  $\text{KNO}_3\text{Aq}$ , using a plate of  $\text{Ag}$  as positive electrode (Wöhler, *A.* 146, 264).—3. By boiling freshly-ppd.  $\text{AgCl}$  with  $\text{KOH Aq}$ , S.G. 1.25 to 1.3 (Mohr, *A.* 66, 65).

**Preparation.**— $\text{KOH Aq}$  is added in slight excess to  $\text{AgNO}_3\text{Aq}$ , the pp. is thoroughly washed with hot water, best in air freed from  $\text{CO}_2$ , and dried at  $c. 80^\circ$ .

**Properties.**—A black powder (brownish when ppd.), with an unpleasant, metallic taste. S.G. 7.52 (Schröder, *B.* 9, 1888); 7.15 (Playfair a. Joule, *C. S. Mem.* 3, 84); 7.25 (Boullay, *A. Ch.* [2] 43, 266). H.F. [ $\text{Ag}_2\text{O}$ ] = 5,900 (*Th.* 3, 381). Slightly sol. water; 1 part dissolves in 3,000 parts water according to Bineau (*C. R.* 41, 509), but according to Abl in 96 parts water at  $18.5^\circ$

(*Oester. Zeit. f. Pharm.* 8, 201 [1884]). Sol.  $\text{NH}_4\text{Aq}$  (for so-called *explosive silver*, formed by dissolving in conc.  $\text{NH}_4\text{Aq}$ , v. SILVER NITRIDES, p. 470). Also sol. aqueous solutions of alkali thiosulphates, chlorides, and cyanides. Sol. aqueous  $\text{MeNH}_2$  and  $\text{EtNH}_2$  (Wurtz, *A. Ch.* [3] 80, 453). Moist  $\text{Ag}_2\text{O}$  absorbs  $\text{CO}_2$  from the air, forming  $\text{Ag}_2\text{CO}_3$ , and reacts with many salts like the alkalis (v. *Reactions*).  $\text{Ag}_2\text{O}$  is decomposed to Ag and O by heat (v. *Reactions*).

*Reactions and Combinations.*—1. Decomposed to Ag and O by heat; Carnelley and Walker (*C. J.* 53, 79) say that O begins to come off at c.  $100^\circ$ , rapid decomposition occurs at c.  $270^\circ$ , and reduction is complete at  $300^\circ\text{--}340^\circ$  (v. also H. Rose, *P.* 85, 317; Joulin, *Bl.* [2] 19, 349; cf. HYDRATED SILVER OXIDE, *infra*).—2. *Antimony sulphide*, *arsenic sulphide*, finely-powdered *sulphur* and *selenium*, amorphous *phosphorus*, and some *organic compounds*, are ignited by rubbing with  $\text{Ag}_2\text{O}$  (Böttger, *J.* 1863, 284).—3. Reduced to Ag by heating to  $100^\circ$  in *hydrogen* (Wöhler, *A.* 30, 4).—4. Finely-divided  $\text{Ag}_2\text{O}$  under water is reduced to Ag by *cadmium*, *copper*, *tin*, and *zinc* (not reduced by Fe or Hg) (Fischer, *P.* 10, 605).—5. AgI and HIO<sub>3</sub> are formed by the reaction of *iodine* with  $\text{Ag}_2\text{O}$  suspended in water (Naquet, *Bl.* 1860, 123); with *chlorine* the products are AgCl,  $\text{HClO}_4\text{Aq}$ ,  $\text{AgClO}$ , and  $\text{AgClO}_2$  (Stas).—6. Moist  $\text{Ag}_2\text{O}$  decomposes many *metallic salts* in solution, ppg. metallic hydroxides, e.g. salts of Bi, Cr, Co, Cu, Fe, Hg (v. H. Rose, *B. B.* 1857, 245).—7. The moist oxide removes halogens from many *halogen-containing organic compounds*, replacing the halogen by OH (e.g.  $2\text{NMe}_2\text{I} + \text{Ag}_2\text{O} \cdot \text{H}_2\text{O} = 2\text{NMe}_2\text{OH} + 2\text{AgI}$ ).—8.  $\text{Ag}_2\text{O}$  reacts with *acids* as a decidedly basic oxide, forming salts  $\text{Ag}_2\text{X}$ , where  $\text{X} = \text{SO}_4$ ,  $2\text{NO}_3$ , &c.—9. A little  $\text{AgNO}_3$  is said to be formed when *nitric oxide* is passed into water with  $\text{Ag}_2\text{O}$  suspended therein (Sabatier a. Senderens, *C. R.* 114, 1476).—10.  $\text{Ag}_2\text{O}$  combines with *lead monoxide*; by allowing a mixture of  $\text{PbO} \cdot x\text{H}_2\text{O}$  and freshly ppd.  $\text{Ag}_2\text{O}$  to stand in contact with  $\text{NaOH}\text{Aq}$ , a compound was obtained, probably  $2\text{Ag}_2\text{O} \cdot \text{PbO}$  (E. Aston, *C. J.* 59, 1093).

HYDRATED SILVER OXIDE (?  $\text{AgOH}$ ). According to H. Rose (*P.* 85, 904), no compound of  $\text{Ag}_2\text{O}$  and  $\text{H}_2\text{O}$  exists. By ppg. an alcoholic solution of  $\text{AgNO}_3$  by  $\text{KOH}\text{Aq}$  at  $-40^\circ$ , Bruce obtained a white flocculent pp. which he supposed to be a hydroxide of Ag (no analyses are given); the pp. darkened on heating, forming  $\text{Ag}_2\text{O}$  and  $\text{H}_2\text{O}$  according to B. (*C. N.* 50, 208). Carey Lea (*Am. S.* 1892, 249) found that ppd.  $\text{Ag}_2\text{O}$  retained some water after drying at  $100^\circ$  for 40 hours, and that all water was removed at  $160^\circ\text{--}165^\circ$  but some O went off also. Carnelley and Walker (*C. J.* 53, 79) say that the product of drying ppd. silver oxide in air for 6 months had the composition  $\text{AgOH}$ , and that this was scarcely decomposed at  $100^\circ$ , but that above this temperature it gave off water and a little O, and was gradually changed to  $\text{Ag}_2\text{O}$  mixed with a little Ag. Some reactions of moist  $\text{Ag}_2\text{O}$  point to the existence of such a compound as  $\text{AgOH}$  (v. SILVER OXIDE, *Reactions*, Nos. 6 and 7).

OXIDE OF SILVER WITH LESS OXYGEN THAN  $\text{Ag}_2\text{O}$ . (*Silver suboxide*.) Many experiments are recorded on the interactions of reducing

agents and Ag salts whereby salts of a lower oxide than  $\text{Ag}_2\text{O}$  were supposed to be formed, and the corresponding oxide was supposed to be ppd. from these salts by alkali. Wöhler (*A.* 30, 1) reduced Ag citrate by heating in H; W. a. Rautenberg reduced ammoniacal solutions of chromate, molybdate, and tungstate of Ag (*A.* 114, 119); W. reduced arsenate and phosphate of Ag by  $\text{FeSO}_4$  (*A.* 146, 263); H. Rose reduced  $\text{AgNO}_3$  in  $\text{NH}_4\text{Aq}$  by ferrous and manganous salts (*P.* 101, 264, 321, 497; v. also Weltzien, *A.* 142, 105). More recent experiments have shown that the products of such reductions in presence of alkali are mixtures containing Ag (v. Pillitz, *Fr.* 27, 496; Newbury, *Am.* 8, 196; Muthmann, *B.* 20, 983; Bailey a. Fowler, *C. J.* 51, 416).

Faraday (*Q. J. S.* 4, 268) supposed that a suboxide of Ag was formed by the action of air on an ammoniacal solution of  $\text{Ag}_2\text{O}$ ; but Bailey and Fowler (*l.c.*) have shown that the substance is a mixture of  $\text{Ag}_2\text{O}$  with a little explosive silver.

The result of a long series of experiments by O. v. d. Pfordten (*B.* 18, 1407; '20, 1458; 21, 2288, 3375) on reducing  $\text{AgNO}_3\text{Aq}$  by  $\text{H}_3\text{PO}_4\text{Aq}$ , alkali bisulphites, and tartaric acid, is that the black pp. thus obtained is not a suboxide of Ag (for some time it was asserted to be  $\text{Ag}_2\text{O}$ ); the accuracy of this result has been strengthened by the critical experimental work of Bailey (*C. N.* 55, 263; *C. J.* 51, 466), and especially of Friedheim (*B.* 20, 2554; 21, 307). F. regards the supposed  $\text{Ag}_2\text{O}$  as a mixture of finely-divided Ag with more or less  $\text{Ag}_2\text{O}$ , or with some organic compounds. V. d. P. (*B.* 21, 2288, 3375) thinks his latest work points to the black substance being a compound of Ag, H, and O in the ratio  $4\text{Ag} : 2\text{H} : \text{O}$ ; he gives it the formula  $\text{Ag}_4\text{H}_2\text{O}$ , or  $\text{Ag}_2\text{OH} \cdot \text{H}$ , and calls it *silver hydrate*. According to Güntz (*C. R.* 112, 861)  $\text{Ag}_2\text{O}$  is produced by the action of steam on  $\text{Ag}_2\text{F}$  at  $160^\circ$ .

The question of the existence and isolation of a compound with less O than  $\text{Ag}_2\text{O}$  cannot be regarded as settled.

OXIDES OF SILVER WITH MORE OXYGEN THAN  $\text{Ag}_2\text{O}$ . By electrolysis conc.  $\text{AgNO}_3\text{Aq}$ , using Pt as positive and Ag as negative electrode, Ritter obtained a black deposit on the Pt; to this black substance R. gave the formula  $\text{Ag}_2\text{O}_2$ , and described it as crystallising in octahedra, *S.G.* 5.474, giving up half its O when carefully heated, with  $\text{NH}_4\text{Aq}$  evolving N, and with  $\text{H}_2\text{O}_2\text{Aq}$  producing Ag,  $\text{H}_2\text{O}$ , and O. A similar production of what seemed to be a peroxide of Ag was noticed by Fischer (*J. pr.* 33, 237) and by Wöhler (*A.* 146, 264). Böttger (*B.* 6, 1398) noticed that the peroxide produced by electrolysis formed explosive Ag and rapidly evolved N, with  $\text{NH}_4\text{Aq}$ . Ag peroxide is formed by the action of ozone on Ag, according to Schönbein (*J. pr.* 41, 821); and of ozone on  $\text{Ag}_2\text{O}$  according to Schiel (*J.* 1864, 118). Ag peroxide is an energetic oxidiser; it sets fire to  $\text{H}_2\text{S}$ , and Au sulphide when rubbed therewith (v. Böttger, *l.c.*).

The analyses made by Fischer (*J. pr.* 33, 237), Mahla (*A.* 82, 289), and Gmelin (*J.* 6, 105) of the peroxide showed the presence of  $\text{H}_2\text{O}$  and  $\text{AgNO}_3$ ; their preparations were probably impure. The analyses of Wallquist (*J. pr.* 81, 179) agreed well with the formula  $\text{AgO}$  (or  $\text{Ag}_2\text{O}_2$ ).

The supposed peroxide of Ag, prepared by electrolysis  $\text{AgNO}_3\text{aq}$ , is regarded by Berthelot (*Bl.* [2] 34, 138) as a compound of  $\text{AgNO}_3$  with an oxide to which he gives the formula  $\text{Ag}_2\text{O}_2$ . By the interaction of  $\text{H}_2\text{O}_2\text{aq}$  with  $\text{Ag}_2\text{O}$ , Berthelot (*l.c.*) obtained black flocks, which were separated from Ag by washing; to this substance B. gives the formula  $\text{Ag}_2\text{O}_2$  as the result of a not very complete analysis; he looks on it as probably identical with the product of the interaction of moist ozone and Ag or  $\text{Ag}_2\text{O}$ . This substance loses O when dried over  $\text{H}_2\text{SO}_4$ ; with acids it gives salts of  $\text{Ag}_2\text{O}$  and evolves O.

**Silver, oxychlorides of.** The action of light on  $\text{AgCl}$  probably produces two oxychlorides of Ag; v. SILVER CHLORIDE, *Action of light on*, p. 468.

**Silver, oxyfluoride of.** To the yellow crystals obtained by evaporating an aqueous solution of  $\text{AgF}$ , Pfandler gives the composition  $\text{AgF} \cdot \text{AgOH}$  (*W. A. B.* 46 [2] 259).

**Silver, phosphides of.** Molten Ag absorbs P; according to Pelletier (*A. Ch.* 13, 101), some of the P remains in combination on cooling, but Warren (*C. N.* 56, 113) says that all except c. .002 p.c. separates as the Ag cools. According to Emmerling (*B.* 12, 152), a compound  $\text{AgP}$  is formed by heating Ag and P in a sealed tube to a dark-red heat; on heating the compound P is given off and Ag remains (v. also Landgrebe, *S.* 60, 128). By heating powdered Ag in vapour of P, Schrötter obtained a grey solid, S.G. 4.63, to which he gave the composition  $\text{Ag}_2\text{P}$ , (*J.* 1869, 247).

Fresenius and Neubauer (*Fr.* 1, 340) obtained a pp. said to contain Ag phosphide and Ag, by leading  $\text{PH}_3$ , or  $\text{CO}$  laden with vapour of P, into  $\text{AgNO}_3\text{aq}$ ; using  $\text{PH}_3$  diluted with  $\text{CO}$ , Poleck and Thümmel (*B.* 16, 2435) obtained a compound, probably  $\text{Ag}_3\text{P} \cdot 3\text{AgNO}_3$ .

**Silver, photosalts of.** Carey Lea (*Am. S.* [8] 33, 349, 480, 489; 34, 33; abstract in *C. J.* 54, 1) gives the name of photosalts to variously-coloured compounds of Ag with the halogens which are very sensitive to light. These bodies are regarded by C. L. as identical with the substances that form the latent images on exposed photographic plates. The photosalts are obtained by the action of reducers, such as  $\text{FeSO}_4\text{aq}$  or  $\text{FeCl}_2\text{aq}$ , on the normal Ag haloids, by reducing Ag salts by such bodies as dextrose or tannin in presence of alkali and treating the products with  $\text{HClaq}$ , or by treating finely-divided Ag with the haloid salts of Cu or Fe and certain other halogenating reagents. The photosalts are regarded by C. L. as compounds of the normal haloids with sub-haloids; from the methods of preparation it seems fairly certain that the coloured bodies called photosalts contained various substances besides Ag and halogen.

**Silver, platinoeyanide of, v. vol. ii. p. 344.**

**Silver, platinosulphocyanide of, v. vol. ii. p. 351.**

**Silver, salts of.** Compounds derived from acids by replacing H by Ag. These salts belong to the type  $\text{AgX}$ , where  $\text{X} = \text{NO}_3, \frac{1}{2}\text{SO}_4, \frac{1}{2}\text{CO}_3, \frac{1}{2}\text{PO}_4$ , &c. Subsalts of the type  $\text{Ag}_2\text{X}$  possibly exist, where X is a halogen. The principal silver salts of oxyacids are: *arsenate* and *arsenite*, *borate*, *bromate*, *carbonates*, *chlorate*,

*chlorite*, *perchlorate* and *hypochlorite*, *chromate* and *dichromate*, *todate* and *periodates*, *molybdates*, *nitrate*, *nitrite* and *hyponitrite*, *phosphates*, *selenate* and *selenite*, *sulphates*, *sulphite* and *thionates*, *tellurates* and *tellurite*. Several salts derived from sulphur-containing acids also exist, the chief of which are: *thio-antimonates* and *antimonites*, *thio-arsenates* and *arsenites*, *thio-carbonate*, *thio-molybdates*, *thio-phosphates* and *phosphites*, and *thio-tellurite*.

**Silver, selenide of,  $\text{Ag}_2\text{Se}$ .** Occurs native, also in combination with selenides of Cu and Pb. Obtained by heating Ag with Se,  $\text{SeO}_2$ , or  $\text{H}_2\text{Se}$ ; also by passing  $\text{H}_2\text{Se}$  into solution of a Ag salt; and by heating  $\text{AgNO}_3\text{aq}$  with Se (Senderens, *C. R.* 104, 176). A grey solid, melting at red heat to silver-white regulus. A little Se is lost by roasting in air; sol. conc. hot  $\text{HNO}_3\text{aq}$ , crystals of  $\text{Ag}_2\text{SeO}$ , separating as liquid cools.

**Silver, selenocyanide of, v. vol. ii. p. 348.**

**Silver, silicides of.** Berzelius found that Ag after fusion with  $\text{SiO}_2$  and C gave a residue of  $\text{SiO}_2$  when dissolved in  $\text{HNO}_3\text{aq}$ . Percy (*Silver and Gold*, 1, 131) failed to obtain any compound of Ag and Si. Warren (*C. N.* 60, 5) obtained compounds or alloys of Ag and Si by heating Ag with  $\text{K}_2\text{SiF}_6$  and Na.

**Silver, silico-fluoride of,  $\text{Ag}_2\text{SiF}_6 \cdot 2\text{H}_2\text{O}$ .** White, deliquescent crystals, melting below  $100^\circ$ ; when strongly heated gives a residue of Ag with some  $\text{SiO}_2$ . Obtained by evaporating a solution of  $\text{Ag}_2\text{O}$  in  $\text{H}_2\text{SiF}_6\text{aq}$  (Marignac, *Ann. M.* [5] 15, 270).

**Silver, sulphides of.** The isolation of any sulphide other than  $\text{Ag}_2\text{S}$  is very doubtful.

**SILVER SULPHIDE  $\text{Ag}_2\text{S}$ . (*Argentite* sulphide.)** Mol. w. not known. Occurs native as *argentite* or *silver glance*. Prepared by heating Ag in vapour of S, or in  $\text{H}_2\text{S}$ , or by the action of  $\text{H}_2\text{S}$  on red-hot  $\text{AgCl}$  (Durocher, *C. R.* 32, 823).  $\text{H}_2\text{S}$  quite free from admixed O is said not to react with Ag. Also prepared by passing  $\text{H}_2\text{S}$  into a solution of a salt of Ag; by boiling  $\text{Ag}_2\text{SO}_4$  or  $\text{AgNO}_3\text{aq}$  with S (Filhol, A. Senderens, *C. R.* 104, 175); and by the contact of  $\text{H}_2\text{SAq}$  with moist  $\text{Ag}_2\text{O}$ . Spring formed  $\text{Ag}_2\text{S}$  by subjecting a mixture of Ag powder and amorphous S to a pressure of several thousand atmospheres, powdering, and compressing again, and repeating this treatment seven or eight times (*Bl.* [2] 39, 641; 41, 488, 492; cf. Friedel, *Bl.* [2] 40, 526). Thomsen (*Th.* 3, 381) gives  $[\text{Ag}_2\text{S}] = 5.340$ . Winssinger (*Bl.* [2] 49, 452) obtained a dilute aqueous solution of colloidal  $\text{Ag}_2\text{S}$  by ppg. from a very dilute solution of a Ag salt, by  $\text{H}_2\text{S}$ , and dialysing; the solution was reddish brown, and did not change after keeping for more than two months.

$\text{Ag}_2\text{S}$  obtained by ppn. is a black solid; when melted, out of air, it solidifies to a grey-black, lustrous, malleable mass, that can be cut with a knife; S.G. 6.85 (Karsten, *S.* 66, 394). S.G. of *argentite* 7.27 to 7.32 (Dauber, *J.* 13, 748). Heated in air slowly goes to Ag, giving off  $\text{SO}_2$ . With conc. boiling  $\text{HClaq}$  gives  $\text{AgCl}$  and  $\text{H}_2\text{S}$ ; hot  $\text{HNO}_3\text{aq}$  forms  $\text{AgNO}_3\text{aq}$  and  $\text{H}_2\text{S}$ ; conc.  $\text{H}_2\text{SO}_4$  produces  $\text{Ag}_2\text{SO}_4$  and  $\text{SO}_2$ . Heated in  $\text{Cl}_2$ ,  $\text{AgCl}$  and  $\text{S}_2\text{Cl}_2$  are formed. Reduced to Ag by action of metals and dilute acid; also reduced by heating with  $\text{PbO}$ ,  $\text{CuO}$ ,

**Fe powder, or Hg** (*cf.* Rammelsberg, *C. J.* 39, 874).

Many compounds of  $\text{Ag}_2\text{S}$  with metallic sulphides occur in minerals, *e.g.* with  $\text{Cu}_2\text{S}$ ,  $\text{Sb}_2\text{S}_3$ ,  $\text{As}_2\text{S}_3$ ,  $\text{Bi}_2\text{S}_3$ , &c. Schneider (*J. pr.* 41, 414) obtained a compound of  $\text{Ag}_2\text{S}$  and  $\text{Bi}_2\text{S}_3$  by fusing the two sulphides together in a covered crucible. Poleck and Thümmel (*Ar. Ph.* [3] 22, 1) obtained  $\text{Ag}_2\text{S} \cdot \text{AgNO}_3$  by passing  $\text{H}_2\text{S}$  into conc.  $\text{AgNO}_3$  as long as it was completely absorbed, washing the greenish pp. with  $\text{HNO}_3$ , and drying; a black amorphous powder, decomposed by water to  $\text{Ag}_2\text{S}$  and  $\text{AgNO}_3$ .

**SILVER SUBSULPHIDE.** According to Güntz (*C. R.* 112, 861),  $\text{Ag}_2\text{S}$  is obtained by the action of  $\text{H}_2\text{S}$  on  $\text{Ag}_2\text{Cl}$ .

**Silver, sulphocyanide of.** *v.* vol. ii. p. 352.

**Silver, telluride of,  $\text{Ag}_2\text{Te}$ .** Occurs native as *hessite*. Prepared by melting together  $\text{Ag}$  and  $\text{Te}$ , by passing vapour of  $\text{Te}$  diluted with much  $\text{N}$  over red-hot  $\text{Ag}$  (Margottet, *C. R.* 85, 1142), and by heating  $\text{AgNO}_3$  with  $\text{Te}$  in a sealed tube (Senderens, *C. R.* 104, 175). Grey, lustrous solid; obtained in needles (octahedral) by the second method given above. *M. M. P. M.*

**SINALBIN**  $\text{C}_{10}\text{H}_{11}\text{N}_2\text{S}_2\text{O}_{10}$ . A glucoside occurring in the seed of white mustard (Will, *Z.* [2] 7, 89; *A.* 199, 150). Prepared by washing the seeds with  $\text{CS}_2$  and extracting the residue with alcohol. Concentric groups of pale-yellow needles (from alcohol), *v.* sol. water, insol.  $\text{CS}_2$  and ether. Reduces Fehling's solution, with formation of  $\text{Cu}_2\text{S}$ . Split up by the ferment myrosin into glucose, sinapine sulphate  $\text{C}_{10}\text{H}_{11}\text{NO}_4\text{H}_2\text{SO}_4$ , and  $\text{C}_6\text{H}_5\text{OCNS}$ , a pungent oil. Aqueous  $\text{AgNO}_3$  produces a similar decomposition, forming a pp. whence  $\text{H}_2\text{S}$  removes  $\text{Ag}$ , leaving in solution sulphate of sinapine and  $\text{C}_6\text{H}_5\text{NO}$  [69]. Coloured yellow by alkalis, and yields  $\text{Na}_2\text{SO}_4$  and sodium sulphocyanide on boiling with  $\text{NaOH}$ .  $\text{HgCl}_2$  gives a white pp.

**SINAMINE** *v.* ALLYL CYANAMIDE.

**SINAPIC ACID**  $\text{C}_{11}\text{H}_9\text{O}_6$ . [192° cor.]. Formed, together with neurine, by boiling sinapine sulphocyanide with alkalis (Von Babo a. Hirschbrunn, *A.* 81, 19; Remsen a. Coale, *Am.* 6, 50). Small yellow prisms (from alcohol), *sl.* sol. cold water, insol. ether. The ammoniacal solution turns brown in air. Salt.— $\text{BaA}''$  (dried at 110°). *Pp.*

**Acetyl derivative**  $\text{C}_{11}\text{H}_9\text{AcO}_5$ . [281°]. Got by boiling the acid with  $\text{Ac}_2\text{O}$ . White crystals, *sol.* hot water.

**SINAPINE**  $\text{C}_{10}\text{H}_{11}\text{NO}_3$ . Occurs as sulphocyanide in seeds of white mustard (O. Henry a. Garot, *J. Ph.* 17, 1, 20, 63; Pelouze, *A. Ch.* [2] 44, 214; *J. Ph.* 17, 271; Boutron a. Robiquet, *J. Ph.* 17, 279; O. Henry a. Plisson, *A. Ch.* [2] 46, 198; Winckler, *Rep. Pharm.* 41, 169; 67, 257; Simon, *P.* 43, 651; 44, 593; Boutron a. Fremy, *J. Ph.* 26, 50; Von Babo a. Hirschbrunn, *A.* 84, 10; Remsen a. Coale, *Am.* 6, 50). Formed also by the action of myrosin on sinalbine (Will a. Laubenheimer, *A.* 199, 162). The free base is known only in solution, and is decomposed on evaporation, leaving a resin. Boiling baryta-water splits it up into neurine  $\text{C}_8\text{H}_9\text{NO}_3$  and sinapic acid.

**Salts.**— $\text{B}''\text{H}_2\text{SO}_4$ , 2aq; rectangular plates, *v.*

*sol.* water and hot alcohol, nearly insol. ether.— $\text{B}''\text{H}_2\text{HgCl}_2$ ; thin prisms.— $\text{B}''\text{HCNS}$ . [176°].

**SINAPOLINE** *v.* DI-ALLYL UREA.

**SINCALINE** *v.* NEURINE.

**SINISTRIN** *v.* INULIN.

**SIPERINE.** An amorphous, resinous, alkaloid occurring, together with bebirine, in the greenheart tree (*Nectandra Rodiei* or *Bebeeru Sipeeri*). It is *v.* *sl.* sol. water, *m.* sol. alcohol, insol. ether (MacLagan, *A.* 48, 106).

**SKATOLE** *v.* METHYL-INDOLE.

**SKOLETINS** *v.* PROTEIDS, *Appendix C.*

**SKIMMIN**  $\text{C}_{15}\text{H}_{15}\text{O}_6$ . [210°]. A glucoside extracted by alcohol from *Skimmia japonica* (Eijkman, *R. T. C.* 3, 204). White needles, *sl.* sol. cold water. Its alkaline solutions show blue fluorescence. It is not poisonous, and does not reduce Fehling's solution.

**Skimmetin**  $\text{C}_{15}\text{H}_{15}\text{O}_6$ . [228°]. Formed, together with glucose, by boiling skimmin with dilute mineral acids. Colourless crystals, *sol.* alcohol and ether. Its solutions exhibit blue fluorescence. Does not reduce Fehling's solution.  $\text{FeCl}_3$  gives a blue colour. Gold chloride gives a rose colour, turning blue and violet.

**SMILACIN**  $\text{C}_{15}\text{H}_{15}\text{O}_6$  (?). Occurs in sarsaparilla root (*Smilax Sarsaparilla*) (Reinsch, *Rep. Pharm.* 82, 145; Thubert, *A.* 6, 204; 14, 76; Batka, *A.* 11, 305; Poggiale, *A.* 13, 84; Henry, *A.* 14, 77; Petersen, *A.* 16, 74; 17, 166; Wright a. Rennie, *C. J.* 39, 237). Nodular groups of leaflets, *m.* sol. hot water and alcohol, *sol.* alkalis.

*Reference.*—PARILLIN.

**SNAKE POISON** *v.* PROTEIDS.

**SOAP** *v.* DICTIONARY OF APPLIED CHEMISTRY.

**SOBREROL**  $\text{C}_{10}\text{H}_{11}\text{O}_2$ . [150°].  $[\alpha]_D = +150^\circ$ .

A product of atmospheric oxidation of turpentine in sunlight (Armstrong a. Pope, *C. J.* 59, 316). Long tables (from alcohol) or monoclinic prisms (from water); *a:b:c* = 2.411:1:0.853;  $\beta = 83^\circ 38'$ . Tastes bitter. Converted by boiling dilute  $\text{H}_2\text{SO}_4$  into an oily isomeric camphor. By crystallising a solution of equal quantities of dextro- and levorotatory sobrerol there is obtained an inactive sobrerol [131°] crystallising from alcohol in trimetric tables; *a:b:c* = 2.424:1:0.827.

**SOCALOIN** *v.* ALLOIN.

**SODA**; *v.* SODIUM HYDROXIDE, p. 479.

**SODIUM** *Na*. *At. w.* 22.995. *Mol. w.* very probably same as *at. w.* (*v. infra*). Melts at  $95.6^\circ$  (Bunsen, *A.* 125, 367),  $97.6^\circ$  (Hagen, *W.* 19, 436); solidifies at  $97.6^\circ$  (Regnault, *J.* 1856, 43). Boils between  $860^\circ$  and  $950^\circ$ , according to Carnelley and Williams (*C. J.* 35, 565); at  $742^\circ$  (Perman, *C. J.* 55, 326). *S.G.*  $985^\circ$  (Schröder, *P.* 106, 226);  $9743$  at  $10^\circ$  (Baumhauer, *B.* 6, 655); *c.*  $74$  at b.p. (Ramsay, *C. J.* 39, 49). *V.D.*  $12.7$  at  $1200^\circ$ – $1500^\circ$  (Scott, *Pr. E.* 14, 410; *v. infra*). *S.H.*  $2734$  from  $-28^\circ$  to  $6^\circ$  (Regnault, *A. Ch.* [3] 46, 257);  $21$  when liquid (Joannis, *A. Ch.* [6] 12, 358). *C.E.* ( $0^\circ$  to  $50^\circ$ )  $0.0007105$  (Hagen, *W.* 19, 436). *E.C.* ( $\text{Hg}$  at  $0^\circ = 1$ )  $18.3$  solid at  $0^\circ$ ,  $8.3$  liquid at  $120^\circ$  (Matthiessen, *P. M.* [4] 12, 199; 13, 81). *T.O.* ( $\text{Ag} = 100$ ) =  $36.5$  (Calvert a. Johnson, *P. M.* [4] 16, 881). *H.O.* [ $\text{Na}^+\text{O}$ ] =  $99,760$  (*Th.* [8] 232). Refraction-equivalent  $\frac{\mu-1}{d} \times \text{at. w.} = 4.4$  (Gladstone, *Pr.* 13, 49);

4·03 (Kanonnikoff, *J. R.* 1884 [i.] 119). Emission spectrum characterised by a double line D, the components of which have the wave-lengths 5895 and 5889 (for detailed measurements of lines v. B., *A.* 1884. 443). For absorption spectrum v. Roscoe a. Schuster (*Pr.* 22, 362). S.V.S. solid 23·3; at b.p. 31 (Ramsay, *C. J.* 39, 49).

*Occurrence.*—Compounds of Na occur widely distributed in large quantities. NaCl is found abundantly as *rock-salt*, also in sea-water and many mineral springs. Large quantities of NaNO<sub>3</sub>, or *Chili saltpetre* occur in S. America. Carbonate, sulphate, and borate of Na are found, in comparatively small quantities, in rocks, and in lake and spring waters. *Cryolite* is a double fluoride of Na and Al. Many silicates contain Na silicate—e.g. *natrolite*, *albite*, *labradorite*, &c. The ashes of many plants contain Na salts, especially NaCl, NaI, and Na<sub>2</sub>SO<sub>4</sub>; some plant ashes are free from Na salts, even when the plants grow near the sea; the ashes of *algae* and some other sea plants are richer in salts of K than in those of Na. NaCl, Na<sub>2</sub>CO<sub>3</sub>, Na<sub>2</sub>HPO<sub>4</sub>, and some other compounds of Na, are found in animal organisms.

*Historical.*—Caustic soda was decomposed by Davy in 1807 (*T.* 1808. 1) by electrolysis; Gay-Lussac a. Thénard heated NaOH with Fe filings and obtained Na (*A. Ch.* 65, 325 [1808]). Brunner (*S.* 71, 201) reduced Na<sub>2</sub>CO<sub>3</sub> by heating with charcoal; this process was made applicable on the large scale by Deville (*A. Ch.* [3] 43, 5 [1855]).

The word *neter* is used by the older Hebrew writers to denote a substance employed for washing clothes; the same, or a similar, substance seems to have been known as *nitron* or *nitrum*, and by the fifteenth century this name was given to saltpetre; when the existence of two similar but distinct substances having detergent properties was recognised, the name *nitrum* was given to one, and the other was called *natrum* or *natron*. The metal obtained from natron was called *natrum*; this name is retained in German, but in English and French the metal is named from *soda*, a word applied in the Middle Ages to designate alkaline substances, and used as synonymous with *nitrum* and *natron*. The symbol Na is universally employed for the metal.

*Formation.*—1. By electrolysis NaOH (*cf.* POTASSIUM, *Formation*, No. 1, p. 298).—2. By reducing Na<sub>2</sub>CO<sub>3</sub> by heating it with charcoal, or with charcoal and very finely-divided iron (Castner, *C. N.* 54, 218).—3. By electrolysis fused NaCl, or conc. NaCl aq, using Hg as the negative electrode.

*Preparation.*—1. An intimate mixture of 80 parts calcined Na<sub>2</sub>CO<sub>3</sub>, 13 parts coal, and 5 parts chalk is heated in an iron bottle with a short exit tube, in a furnace, until vapours of Na appear at the mouth of the tube, when a small flat receiver, made of sheet iron, is adapted to the tube; when the receiver is full of Na it is removed, and the metal is taken out under mineral oil (*cf.* POTASSIUM, *Preparation*, p. 298). As Na does not combine with CO, the difficulty which attends the preparation of K because of the formation of KCO, does not occur with Na.—2. A mixture of NaOH, C, and Fe is heated in egg-shaped iron retorts, connected with cast-iron condensers

about 3 ft. long and 5 in. diameter, and having small openings near the nozzles through which the molten Na runs into pots placed beneath. The mixture of C and Fe is made by heating a mixture of very finely divided iron and pitch; this is heated with NaOH in approximately the proportion 6NaOH:2C:4Fe. (For details v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 422.)

The metal is purified by pressing through linen under rock oil kept at c. 100°; it must be kept under oil free from O. Rosenfeld (*B.* 24, 1658) recommends to soak the metal in a mixture of 1 part amyl alcohol and 3 parts petroleum, and to rub it with a rag soaked in the same mixture, till the surface is bright; then to let it remain under petroleum with 5 p.c. amyl alcohol; to wash it with pure petroleum, and to keep it under petroleum containing from  $\frac{1}{2}$  to 1 p.c. amyl alcohol. The film of sodium-amyl oxide which forms is easily rubbed off with filter paper.

*Properties.*—A silver-white, lustrous metal; usually described as whiter than K, but according to Long (*C. J.* 13, 122) a clean surface has a pale rose colour. By melting Na in a glass tube, narrowed at one place, and filled with coal-gas or H, and allowing the semi-solidified metal to flow slowly through the narrowed part of the tube, Na is obtained in lustrous, white, quadratic octahedra, with a rosy sheen (Long, *l.c.*; *cf.* Böttger, *B.* 7, 1536). According to Linnemann (*J. pr.* 75, 128), the surface of a freshly-cut piece of Na shows green phosphorescence that soon disappears, but returns again at 60°–70° (*cf.* Baumhauer, *J. pr.* 102, 123, 361). A sublimate, in a very thin film on glass, shows a greenish blue colour in transmitted light (Dudley, *C. N.* 66, 163; Newth, *N.* 47, 55). The vapour obtained by boiling Na in an atmosphere of H is colourless in thin layers, and violet to purple when seen in thick layers (Roscoe a. Schuster, *Pr.* 22, 362; Carnelley a. Williams, *C. J.* 35, 565). At the ordinary temperature Na is as soft as wax; it is ductile at 0°, and fairly hard at –20°; at c. 50° it is pasty; it melts at c. 96°, and boils at c. 750° (v. beginning of this article). Na dissolves in liquid NH<sub>3</sub>, forming a blue liquid (*v.* SODIUM-AMMONIUM, p. 475). A freshly-cut surface of Na exposed to air becomes rapidly covered with a film of oxide; Na is said to be unchanged at the ordinary temperature in perfectly dry air. It decomposes cold water rapidly, but the H evolved does not generally take fire. Na must be kept under a liquid free from O, such as mineral oil or naphtha (*v.* *Preparation*, *supra*).

The atomic weight of Na has been determined (1) by converting NaCl into AgCl (Berzelius, *P.* 8, 189 [1826]; Pelouze, *C. R.* 20, 1047 [1845]; Dumas, *A. Ch.* [3] 55, 182 [1859]; Stas, *Stas. Rech.* 78); (2) by reducing NaClO<sub>2</sub> to NaCl (Penny, *T.* 129 [1] 25 [1839]); (3) by converting NaCl into NaNO<sub>3</sub> (Stas, *Novv. R.* 248 [1865]); (4) by determining S.H. of Na.

The molecular weight of Na is not known with certainty. Dewar a. Dittmar (*C. N.* 27, 121) and D. a. Scott (*Pr.* 29, 206 [1879]) obtained numbers that indicated a mol. w. of 23; but the values varied considerably. D. a. S. used a vessel of wrought iron. Scott (*Pr. E.* 14, 410 [1888]) ob-

tained fairly concordant results, giving values for V.D. varying from 11.8 to 15, using a Pt vessel heated above the m.p. of cast iron; but V. Meyer's experiments (B. 13, 391 [1880]) seemed to indicate that Na vapour attacks vessels of Ag or Pt. Mitscherlich (A. 12, 173 [1834]) found that vessels of hard glass were also attacked; and Rieth (B. 4, 807 [1871]) got no constant results by using a vessel of Cu. The values obtained by Scott were so constant that there is a large probability in favour of the monatomicity of the molecule of gaseous Na. Ramsay (C. J. 55, 621) dissolved Na in Hg and measured the decrease of vapour-pressure of the Hg thereby produced; assuming the mol. w. of liquid Hg to be 200; and assuming that equal vols. of dilute solutions in Hg contain equal numbers of molecules, the results gave values for mol. w. of Na varying from 15 to 21.5.

The V.D. of no compound of Na has been determined; from the analogy of K, Rb, Cs, and Ag, the atom of Na is probably monovalent in gaseous molecules.

Sodium is a strongly positive element; it comes after Rb, Cs, and K in order of decreasing electropositivity (Bunsen). In all its compounds Na reacts as a metal; it does not enter into the composition of any negative radicles. Na forms few basic salts and no oxyhaloid compounds; its haloid compounds are very stable towards heat. Na is closely related to Li, K, Cs, and Rb (v. ALKALIS, METALS OF THE, vol. i. p. 114), and less closely to Cu, Ag, and Au (v. COPPER GROUP OF ELEMENTS, vol. ii. p. 250).

**Reactions and Combinations.**—1. Heated in air or oxygen,  $\text{Na}_2\text{O}$  and  $\text{Na}_2\text{O}_2$  are formed (v. *Oxides*, p. 482). According to von Bonsdorff (P. 41, 296), Na is unchanged in quite dry air at the ordinary temperature.—2. Na absorbs hydrogen at c.  $300^\circ$ , probably forming a compound (v. *Hydride*, p. 479).—3. Combines with chlorine, bromine, and iodine when heated with these elements (v. *Chloride, bromide, and iodide*).—4. Forms sulphides, by reacting with sulphur at the ordinary temperature; combines, when heated, with selenium and tellurium, also with arsenic and phosphorus (v. *Sulphide*, p. 483, *Selenide*, p. 482, *Telluride*, p. 483, *Arsenide*, p. 476, and *Phosphide*, p. 482).—5. Alloys with several metals (v. *Alloys, infra*).—6. Na decomposes water at the ordinary temperature, forming  $\text{NaOH}$  and  $\text{H}_2$ ; much heat is produced, but the  $\text{H}_2$  does not generally take fire unless the reaction is slackened, and friction is increased, by thickening the water by gum &c., or placing the Na on moist filter paper (v. Ducatel, *Ann. S.* 25, 90; Serullas, *A. Ch.* [3] 40, 329). If Na is allowed to react with water in a cylinder standing over water, the  $\text{H}_2$  collecting in the cylinder, a violent explosion sometimes occurs, probably due to formation of a peroxide that is then decomposed with evolution of  $\text{O}_2$ , which mixes with the  $\text{H}_2$  (Böttger, *J. pr.* 85, 397; Griffin, *J.* 1856, 320).—7. Na reduces many oxides at high temperatures, e.g.  $\text{CO}$ ,  $\text{N}_2\text{O}$ ,  $\text{B}_2\text{O}_3$ ,  $\text{P}_2\text{O}_5$ ,  $\text{As}_2\text{O}_3$ ,  $\text{HgO}$ ,  $\text{CuO}$ ,  $\text{Ag}_2\text{O}$ ,  $\text{PbO}$ ,  $\text{ZnO}$ ,  $\text{Fe}_2\text{O}_3$ , &c.—8. Many carbonates, sulphates, nitrates, phosphates, and silicates are reduced when strongly heated with Na.—9. Many metallic chlorides are reduced by heating with Na, e.g.  $\text{MgCl}_2$ ,  $\text{AlCl}_3$ , &c.—10. By heating with solid caustic potash to c.  $170^\circ$ , an

alloy of Na and K is formed (v. Williams, *C. N.* 3, 21; Wanklyn, *C. N.* 3, 66).—11. Heated in ammonia gas,  $\text{NaNH}_2$  is formed (v. *Amide, infra*), and when this is more strongly heated  $\text{Na}_3\text{N}$  is formed (v. *Nitride*, p. 482).—12. Na reacts with aqueous solutions of acids to form salts  $\text{NaX}$ , where X is a monovalent acidic radicle.

Sodium, alloys of. Na forms alloys with many metals; these alloys are generally formed by directly melting the metals together, or by reducing the chlorides by Na. By the action of sodammonium (v. *infra*) on Sb, Bi, Pb, Joannis (C. R. 114, 585) says that alloys of Na with these metals are obtained agreeing in composition with the formulae  $\text{Na}_3\text{Sb}$ ,  $\text{Na}_3\text{Bi}$ , and  $\text{Na}_3\text{Pb}$ . Schumann (W. 43, 101) obtained a definite alloy of Na and Hg corresponding with the formula  $\text{NaHg}$ , (v. also *SODAMMONIUM, infra*).

Sodium, aluminates of, v. vol. i. p. 141.

Sodium, amide of,  $\text{NaNH}_2$ . (*Sodamide*.) Mol. w. not determined. First prepared by Gay-Lussac and Thénard (*Recherches physico-chimique*, 1, 354) by heating Na in  $\text{NH}_3$ ; the Na absorbed 142 to 163 vols.  $\text{NH}_3$  and 100 vols.  $\text{H}_2$  were produced. Prepared by Beilstein and Geuther (A. 108, 88) by driving out the air from several flasks, connected by tubes, by a stream of dry  $\text{H}_2$ , then placing a few grams Na in each flask, replacing the  $\text{H}_2$  by dry  $\text{NH}_3$ , free from  $\text{CO}_2$  (Drechsel, *J. pr.* [2] 16, 203), and heating the flasks on sand-trays; the Na melts and swims on the blue-green liquid that forms. When the Na has all disappeared the liquid is allowed to cool; the solid that forms is at first brown, but when quite cold it forms a crystalline, olive-green mass. Also obtained by the gradual decomposition at the ordinary temperature (hastened by light) of sodammonium; as the liquid decomposes, crystals of  $\text{NaNH}_2$ , 1 mm. long, are formed; these crystals are said to be white (Joannis, *C. R.* 112, 392).

Heating in  $\text{CO}$  produces  $\text{NaCN}$  and  $\text{H}_2\text{O}$ , along with  $\text{NaOH}$  and  $\text{NH}_3$ . When heated in  $\text{CO}_2$  much  $\text{NH}_3$  is given off, and the final products are  $\text{H}_2\text{O}$  and  $\text{CN.NNa}_2$  (disodium salt of cyanamide; v. vol. ii. pp. 313, 314); B. a. G. (l.c.); Drechsel (l.c.).  $\text{CS}_2$  reacts to form  $\text{NaSCN}$  and  $\text{H}_2\text{S}$ , then  $\text{NH}_3$  is given off, and  $\text{NaSH}$  remains. Dilute  $\text{HCl}$  reacts violently, producing  $\text{NaCl}$  and  $\text{NH}_4\text{Cl}$ .  $\text{EtCl}$  forms  $\text{NaCl}$ ,  $\text{NH}_3$ , and  $\text{C}_2\text{H}_5$ , but no  $\text{EtNH}_2$ . Heated with  $\text{O}$  the products are  $\text{NaCN}$  and  $\text{H}_2$  (Drechsel, *J. pr.* [2] 21, 91). When strongly heated  $\text{NaNH}_2$  gives off  $\text{NH}_3$  and leaves  $\text{Na}_3\text{N}$  (v. *SODIUM NITRIDE*, p. 482).

Sodium-ammonium or Sodammonium. Weyl (P. 121, 611; 123, 350) obtained a blue liquid, by the action of liquid  $\text{NH}_3$  on Na, which he regarded as a compound or alloy of Na and  $\text{NH}_3$ . As Na remained when the  $\text{NH}_3$  was allowed to evaporate, Seeley (C. N. 23, 169) looked on the blue liquid as a solution of Na in liquid  $\text{NH}_3$ . Joannis (C. R. 109, 900, 965; 110, 238) found that the vapour-pressure of a solution of Na in liquid  $\text{NH}_3$  decreased to a limit wherewith it became constant if temperature remained unchanged; that on then removing more  $\text{NH}_3$  a copper-red solid separated, and that  $\text{NH}_3$  was then given off at constant pressure till only Na remained. When the last part of the change commenced, the copper-red substance contained

# SODIUM-AMMONIUM

Na and  $\text{NH}_3$  in the ratio  $\text{Na}:\text{NH}_3$ ; the evolution of  $\text{NH}_3$  at constant pressure was regarded by J. as due to the dissociation of a compound  $\text{NaNH}_2$ . The heat of formation of  $\text{NH}_3$  from gaseous  $\text{NH}_3$  and solid Na was determined by J. to be 5,200, and from liquid  $\text{NH}_3$  and solid Na to be 800, cal. J. determined the lowering in the freezing-point of liquid  $\text{NH}_3$  by solution in it of  $\text{NaNH}_2$ , and so calculated the mol. formula of this body to be  $\text{Na}_2\text{N}_2\text{H}_4$  (C. R. 115, 820). The solution of  $\text{Na}_2\text{N}_2\text{H}_4$  in liquid  $\text{NH}_3$  is decomposed by Sb, Pb, and Hg, but not by Al, Cu, Ag, or Zn; the final product of the action of Pb is  $\text{Pb}_2\text{Na}_2\text{NH}_3$ ; by dropping the liquid on to Hg, and washing the product with liquid  $\text{NH}_3$ , the crystalline amalgam  $\text{NaHg}$  was obtained (J., C. R. 113, 795). According to J. (C. R. 112, 892),  $\text{Na}_2\text{N}_2\text{H}_4$  decomposes slowly at the ordinary temperature to  $\text{NaNH}_2$  and H. With excess of NaCl the blue liquid becomes colourless and  $\text{NaNH}_2$  separates; the compound  $\text{NH}_2\text{Na}_2\text{Cl}$  is first formed, and is then decomposed by the liquid  $\text{NH}_3$  to  $\text{NaNH}_2$  and NaCl. By passing dry O into  $\text{Na}_2\text{N}_2\text{H}_4$  in liquid  $\text{NH}_3$  at  $-50^\circ$ , J. (C. R. 116, 1370) obtained  $\text{NH}_2\text{Na}_2\text{OH}$ ; by the prolonged action of O he obtained  $\text{Na}_2\text{O}$ .

Sodium, arsenates of, v. vol. i. p. 309.

Sodium, arsenide of. Gay-Lussac and Thénard found that Na combined directly with As. According to Landolt (A. 89, 210)  $\text{Na}_3\text{As}$  is formed, as a silver-white solid, by heating the elements in the ratio  $3\text{Na}:\text{As}$ . A compound of Na and As is also formed when Na is heated in  $\text{AsH}_3$ . Decomposed by water, giving off  $\text{AsH}_3$ .

Sodium, arsenites of, v. vol. i. p. 307.

Sodium, aurobromate of,  $\text{NaAuBr}_2$ . Orange-red prisms, by dissolving NaBr in  $\text{AuBr}_3\text{Aq}$  (cf. vol. ii. p. 649).

Sodium, aurochlorate of,  $\text{NaAuCl}_4$ . By dissolving NaCl in  $\text{AuCl}_3\text{Aq}$  (cf. vol. ii. p. 650).

Sodium, borates of, v. vol. i. p. 529.

Sodium, boride of. The product of the reduction of  $\text{B}_2\text{O}_3$  by Na may contain a compound of B and Na.

Sodium borofluoride v. vol. i. p. 526.

Sodium, bromide of, NaBr. Mol. w. not certainly known, but probably 102.745 (= NaBr). Melts at  $709^\circ$  (Carnelley, C. J. 33, 279); at  $727^\circ$  (v. Meyer a. Riddle, B. 26, 2443). S.G. 3.079 at  $17.5^\circ$  (Kremers, P. 93, 443); 3.198 at  $17.3^\circ$  (Favre a. Valson, C. R. 77, 579); 2.448 when molten (Quincke, P. 138, 141). Kremers (P. 99, 443) gives solubilities as follows:—

Temp.	S.	Temp.	S.
0°	77.5	60°	111.1
20	88.4	80	112.5
40	104.2	100	114.9

Coppet (A. Ch. [4] 25, 506; [5] 30, 411) gives the following:—

Temp.	S.	Temp.	S.
44.1°	115.6	86°	118.8
51.5	116.2	90.5	119.7
55.1	116.8	100.3	120.6
60.3	117	110.6	122.7
64.5	117.8	114.3	124
74.5	118.4		

C. represents S. of NaBr as  $110.34 + .1075t$  when  $t$  varies from  $44^\circ$  to  $114^\circ$ . S. in alcohol 90 p.p. = 6. B.P. of saturated NaBrAq =  $121^\circ$ . S.G.

of NaBrAq given by Kremers a. Gerlach (P. 6, 279) at  $15^\circ$  as follows:—

S.G. NaBrAq	P.C. NaBr	S.G. NaBrAq	P.C. NaBr
1.04	5	1.281	30
1.08	10	1.344	35
1.125	15	1.410	40
1.174	20	1.483	45
1.226	25	1.565	50

H.F.  $[\text{Na}, \text{Br}] = 85,770$ ;  $[\text{Na}, \text{Br}, \text{Aq}] = 85,580$  (Th. 3, 232).

Formation.—1. By passing Br vapour over Na. According to Merz and Weith (B. 6, 1518), Na remains unchanged for months in liquid Br at the ordinary temperature, and even at  $100^\circ$  or  $200^\circ$  the formation of NaBr proceeds very slowly.—2. By treating BrAq with iron filings, boiling the solution of  $\text{FeBr}_2\text{Aq}$  with  $\text{NaOHAq}$ , filtering, and evaporating (Henry, J. Ph. 15, 54).—3. By neutralising  $\text{HBrAq}$  by  $\text{NaOHAq}$  or  $\text{Na}_2\text{CO}_3\text{Aq}$ , and evaporating.—4. By decomposing  $\text{CaBr}_2\text{Aq}$  by  $\text{Na}_2\text{SO}_4$ , filtering after some time, adding  $\text{Na}_2\text{CO}_3$ , as long as turbidity is produced, filtering, and evaporating (Klein, A. 128, 237).—5. By decomposing pure  $\text{NH}_4\text{Br}$  by  $\text{NaOHAq}$  or  $\text{Na}_2\text{CO}_3\text{Aq}$ , and evaporating (Castelha, C. H. 70, 1050).

Preparation.—Br is added, little by little, to moderately conc. pure  $\text{NaOHAq}$  (v. Sodium hydroxide, p. 479) till the liquid is slightly yellow; the liquid is evaporated to dryness; the residue of  $\text{NaBrO}$ , and NaBr is strongly heated, in a porcelain dish, till traces of Br are given off, the residue is dissolved in water, evaporated, and allowed to crystallise at a temperature not under  $30^\circ$  ( $\text{NaBr}$  2aq separates below  $30^\circ$ ).

Properties.—Lustrous, white cubes; strong alkaline taste; reaction in water is neutral. Dissolves easily in water, with slight fall of temperature  $[\text{NaBr}, \text{Aq}] = -190$  (Th. 3, 232); NaBr separates from this solution at c.  $30^\circ$ , but at the ordinary temperature crystals of  $\text{NaBr}$  2aq are formed.

Reactions.—1. Chlorine reacts with NaBrAq to give  $\text{NaClAq}$  and Br.—2. Heated with potassium chromate and sulphuric acid, Br is given off; NaCl under similar conditions gives  $\text{CrO}_2\text{Cl}_2$ .—3. Conc. sulphuric acid forms  $\text{HBr}$ , Br, and  $\text{SO}_2$ ; by using dilute  $\text{H}_2\text{SO}_4\text{Aq}$  (c. 30 p.c.) a mere trace of Br is obtained (v. Addyman, C. J. 61, 94).—4. Potassium permanganate does not react with NaBrAq even when boiled, but addition of a little  $\text{H}_2\text{SO}_4\text{Aq}$  causes evolution of Br (Hempel, A. 107, 160).

Combinations.—1. With water to form  $\text{NaBr} \cdot 2\text{H}_2\text{O}$ . This hydrate separates from solutions of NaBr saturated when hot and cooled to under  $30^\circ$ ; it crystallises in monoclinic prisms, which melt at  $50^\circ$ , leaving NaBr.—2. With many bromides of less positive metals, e.g. with  $\text{PbBr}_2$ , to form  $\text{PbBr}_2 \cdot 2\text{NaBr}$ , and  $\text{CdBr}_2$ , to form  $\text{CdBr}_2 \cdot 5\text{NaBr} \cdot 5\text{aq}$  (v. the various metallic bromides).—3. With arsenious oxide to form  $\text{NaBr} \cdot \text{As}_2\text{O}_3$  (Büddorf, B. 21, 3051).

Sodium, chloride of, NaCl. (Common salt.) Mol. weight not known with certainty, but probably 58.365 (= NaCl). Melts at  $772^\circ$  (Carnelley, C. J. 83, 280); at  $851^\circ$  (Meyer a. Riddle, B. 26, 2443). S.G. 2.16 at  $0^\circ$  (Quincke, P. 138, 141); 2.157 at  $4^\circ$  (Schröder, P. 106, 220);

(7) 1.612 at m.p. (Braun, *B. 7*, 958); 2.04 after fusion (Quinke, *P. 135*, 842); for other values *v. Clarke's Table of Specific Gravities* [2nd ed.] 20. S.H. 15° to 98° 21401 (Regnault, *A. Ch.* [3] 1, 129; *v. also* Kopp, *T. 155* [1] 71). Vol. at 40° = vol. at 0° (1 + 0.0012117 × 40) (Fizeau, *C. R.* 64, 314). H.F. [Na, Cl] = 97,690 (*Th.* 3, 232). Poggiale (*A. Ch.* [3] 8, 469) gives following data for solubility in water:—

Temp.	S.	Temp.	S.
-15°	32.73	40°	36.64
-10	33.49	50	36.98
-5	34.22	60	37.25
0	35.52	70	37.88
+5	35.63	80	38.22
9	35.74	90	38.87
14	35.87	100	39.61
25	36.13	109.7	40.35

Coppet (*A. Ch.* [5] 30, 411) gives S. above 20° to 109° = 34.359 + .0527*L*. Gerlach (*Fr.* 8, 281) gives the following data:—

S.G. NaClAq at 15°			
1 p.c.	1.00725	10 p.c.	1.14315
2 "	1.01450	11 "	1.15107
3 "	1.02174	12 "	1.15931
4 "	1.02899	13 "	1.16755
5 "	1.03624	14 "	1.17580
6 "	1.04366	15 "	1.18404
7 "	1.05108	16 "	1.19228
8 "	1.05851	17 "	1.20098
9 "	1.06593	18 "	1.20433

1000 c.c. of NaClAq saturated at 15° contain 818.479 g. NaCl and 888.669 g. water (Michel a. Kraft, *J.* 1854. 293). NaClAq containing 29.4 to 29.5 p.c. NaCl boils at 109.25° (at 760 mm. pressure) and freezes at -21.3° (Karsten, *Salinenkunde* [Berlin, 1847] 2, 38). The following freezing-points are given by Karsten (*l.c.*) for NaClAq (*cf.* Rüdorff, *P.* 114, 63; and de Coppet, *A. Ch.* [4] 25, 509):—

P.C. NaCl	F.P.	P.C. NaCl	F.P.
2	-1.32°	16	-11.69
4	-3.024	20	-14.44
6	-4.52	22	-15.78
8	-5.99	24	-17.11
10	-7.44	26	-18.42
12	-8.88		

For freezing-points of dilute NaClAq, containing from c. .006 to c. 2.6 p.c. NaCl, *v. Jones* (*Z. P. C.* 11, 210).

Solution of NaCl in water is accompanied by lowering of temperature and contraction; 86 parts NaCl in dissolving in 100 parts water at 12.6° lower the temperature to 10.1° (Rüdorff, *B.* 2, 68); Thomsen gives [NaCl, Aq] = -1180 (*Th.* 3, 232). By mixing 36 parts NaCl with 100 parts snow, temperature falls to -21.3° (Rüdorff, *P.* 114, 79; 122, 337).

NaCl is insol. absolute alcohol; Girardin (*A. Ch.* [4] 5, 146) gives the following data for S. in aqueous alcohol S.G. .9282; 10.9 at 4°, 11.1 at 10°, 11.43 at 13°, 11.9 at 23°, 12.3 at 32°, 13.1 at 44°, 13.8 at 51°, 14.1 at 60°. Schiff (*A.* 118, 365) gives S. in alcohol at 15° as follows; 28.33 in 10 p.c. alcohol, 13.25 in 40 p.c., 5.93 in 60 p.c., 1.22 in 80 p.c. NaCl crystallises in the regular system, generally in cubes, sometimes in octahedra.

**Occurrence.**—As rock salt, or halite, in very

large quantities very widely distributed; in sea-water, many salt lakes, brine springs, and most mineral springs.

**Formation.**—1. By burning Na in moist Cl. According to Wanklyn (*C. N.* 20, 271), dry Cl does not combine with Na even at the M.P. of the metal; Donny a. Mareska (*C. R.* 20, 817) state that Na is unacted on by liquid Cl at -80°.—2. By neutralising NaOH<sub>Aq</sub> or Na<sub>2</sub>CO<sub>3</sub>Aq by HClAq, and evaporating.—3. By the reaction of excess of conc. HClAq with several salts of Na, *e.g.* Na<sub>2</sub>SO<sub>4</sub>.—4. By strongly heating Na<sub>2</sub>SO<sub>4</sub> with excess of NH<sub>4</sub>Cl; also by decomposing Na<sub>2</sub>SO<sub>4</sub>Aq by several chlorides, *e.g.* MgCl<sub>2</sub> or CaCl<sub>2</sub>.—5. As a by-product in making KNO<sub>3</sub> by the reaction of KCl with NaNO<sub>3</sub>. 6. By the reduction of many chlorides by Na.

**Preparation.**—Pure NaHCO<sub>3</sub> is prepared by washing a large quantity of the ordinary 'pure' salt, in fine powder, with cold water till the washings cease to be clouded on addition of a salt of Ag or Ba; after boiling with slight excess of HNO<sub>3</sub>Aq, the residue is dried and heated to dull redness in a Pt dish; a boiling saturated solution of the Na<sub>2</sub>CO<sub>3</sub> thus obtained is prepared, filtered, and shaken while crystallising to insure the formation of small crystals; the crystals are dried by suction by a water-pump, they are then twice moistened with cold water to remove all mother-liquor, and crystallised three times from water. The pure Na<sub>2</sub>CO<sub>3</sub> is dissolved, and NaCl is formed by passing in a stream of pure HCl gas (obtained by heating pure conc. HClAq); a little pure NH<sub>4</sub>Cl is added to the solution (for preparation of pure NH<sub>4</sub>Cl *v. vol. i.* p. 197, under Ammonia, *Preparation*, No. 3), which is then evaporated to dryness in a Pt retort; the residue is very strongly heated, and then dissolved in water; after standing for 24 hours the solution is poured off (from any Al<sub>2</sub>O<sub>3</sub>.xH<sub>2</sub>O and SiO<sub>2</sub> that settle), a little pure NH<sub>4</sub>Cl is added, the solution is evaporated to dryness in a Pt retort, the residue is strongly heated for some time, and after partial cooling the still liquid NaCl is poured off (from Pt, SiO<sub>2</sub>, and Al<sub>2</sub>O<sub>3</sub>) into a Pt dish; when cold, the NaCl is dissolved in water, the solution is poured off after 2 days and evaporated to dryness in a Pt retort, and the residue is fused in a Pt vessel (Stas, *Chem. Propert.* 275).

For preparation of NaCl from rock salt, brine, and sea-water, *v. DICTIONARY OF APPLIED CHEMISTRY*, vol. iii. p. 429.

**Properties.**—A pure, white, lustrous solid; crystallises in the regular system, generally in cubes. Decrepitates when heated. NaCl is diathermanous. Solution in water is neutral to indicators, and has a bitter taste. Pure NaCl is very slightly hygroscopic, taking up c.  $\frac{1}{2}$  p.c. water from moist air (Stas, Karsten). Melts at c. 772°; vapourises markedly at white heat in a stream of N (*v. Stas, l.c.*). NaCl is almost wholly ppd. from an aqueous solution by leading in HCl (Margueritte, *C. R.* 4°, 50); also ppd. from a conc. solution by cold conc. NaOH<sub>Aq</sub> (Berthelot *C. R.* 76, 111); also by warming a conc. solution with excess of NaBr or NaI and cooling (von Hauer, *J. pr.* 98, 137). Saturated NaClAq deposits the hydrate NaCl.2aq at -7° to c. -22°, and at c. -23° NaCl.10aq separates (*v. Hydrates*, under *Combinations*, p. 478).

**Reactions.**—1. According to de Sanderval (C. R. 116, 641), when NaCl is vapourised around a porous tube Cl collects in the inside of the tube.—2. Electrolysis of NaClAq produces Cl and NaOHAq, but NaClO<sub>2</sub>Aq and NaClO<sub>3</sub> are soon formed by secondary reactions; if a diaphragm of asbestos is used, the cathode being on one side and the anode on the other, and CO<sub>2</sub> is passed into the NaClAq, Cl is given off and Na<sub>2</sub>CO<sub>3</sub> is formed (v. Hempel, B. 22, 2475).—3. Fusion with potassium produces KCl and Na.—4. Fusion with sulphur is said to form Na<sub>2</sub>S and S<sub>2</sub>Cl<sub>2</sub>, but this is denied by Karsten; NaCl is not decomposed by hydrogen, or oxygen, at a red heat.—5. Superheated steam has no reaction, according to Kunheim (J. 1861. 149); there is a slight reaction, according to Lunge (Soda-industrie, 2, 288).—6. Sulphuric anhydride vapour is absorbed, without heating, giving S<sub>2</sub>O<sub>3</sub>NaCl (Na salt of SO<sub>2</sub>(Cl).O.SO<sub>2</sub>.OH); according to Schultz-Sellack (B. 4, 112) more SO<sub>2</sub> is then absorbed, and a compound approximately NaCl<sub>4</sub>SO<sub>3</sub> is formed; on heating Na<sub>2</sub>SO<sub>3</sub>, SO<sub>2</sub> and Cl are produced. By heating with liquid sulphuric anhydride S<sub>2</sub>O<sub>3</sub>Cl<sub>2</sub> is formed (Rosenstiehl, C. R. 53, 658).—7. Decomposed by heating to c. 500° in a mixture of air, sulphur dioxide, and water vapour, giving Na<sub>2</sub>SO<sub>3</sub> and HCl (Hargreaves and Robinson's process for making Na<sub>2</sub>SO<sub>3</sub>; v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 444).—8. NaCl is decomposed, with formation of oxychlorides or chlorides, by heating with phosphoric, chromic, or molybdic anhydride, or with antimonie oxide; decomposition occurs with silica, boric oxide, alumina, and tungstic oxide only in presence of air or water vapour, forming silicate, borate, aluminate, or tungstate of Na, and HCl; in presence of water vapour Cl is evolved in some of these reactions (v. Schulze, J. pr. [2] 21, 407; Delalande a. Prudhomme, Bl. 20, 74; Gorgeu, A. Ch. [5] 10, 145). Lead oxide decomposes NaClAq, forming PbCl<sub>2</sub> and NaOHAq (Scheele); but molten NaCl is said not to interact with PbO. Moist NaCl mixed with caustic lime and exposed to air becomes covered with an efflorescence of Na<sub>2</sub>CO<sub>3</sub> crystals. Magnesia interacts with NaClAq, in presence of CO<sub>2</sub>, to form NaHCO<sub>3</sub> and MgCl<sub>2</sub> (Weldon; Wagner, J. 1873. 256).—9. Sulphuretted hydrogen partially decomposes hot NaCl to Na<sub>2</sub>S, more completely in presence of steam (Kinzett, C. J. [2] 11, 456).—10. Many metallic sulphides, e.g. Cu<sub>2</sub>S, produce Na<sub>2</sub>SO<sub>3</sub> and metallic chlorides (sometimes Cl is set free) when roasted in air with NaCl.—11. Several metallic sulphates when fused with NaCl produce Na<sub>2</sub>SO<sub>3</sub> and metallic chlorides—e.g. PbSO<sub>4</sub>, ZnSO<sub>4</sub>, CuSO<sub>4</sub>; some of these sulphates react also with NaClAq. Some sulphates form Na<sub>2</sub>SO<sub>4</sub> and give off Cl when heated with NaCl, e.g. FeSO<sub>4</sub> (v. Barreswil, J. Ph. [8] 12, 456).—12. Fusion with potassium chlorate only decomposes a trace of NaCl (Schulze, J. pr. [2] 21, 407).—13. Ammonium oxalate heated with NaCl forms Na<sub>2</sub>CO<sub>3</sub> and distinct quantities of NaCN (Presenius); addition of (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> to hot saturated NaClAq ppts. Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.—14. Potassium carbonate reacts with NaClAq to form Na<sub>2</sub>CO<sub>3</sub>Aq and KClAq; if CO<sub>2</sub> is passed in NaHCO<sub>3</sub> ppts.—15. Ammonium bicarbonate and NaClAq produce NaHCO<sub>3</sub> and

NH<sub>4</sub>ClAq. Passage of CO<sub>2</sub> into NaClAq saturated with NH<sub>3</sub> ppts. NaHCO<sub>3</sub> (v. Ammonia-soda process, in DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 494).—16. Sulphuric acid decomposes NaCl, forming HCl, and NaHSO<sub>4</sub>, or Na<sub>2</sub>SO<sub>4</sub>, according to the temperature. The Leblanc process for making sodium carbonate takes advantage of this reaction (v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 459).—17. Evaporation with excess of nitric acid produces NaNO<sub>3</sub> and HCl.—18. NaCl is readily decomposed by hydrofluoric acid, also by hydrofluosilicic acid.—19. Carbonic acid is said to set free some HCl from NaClAq (v. H. Müller, B. 3, 40; Funk, Chem. Zeitung, 1879. 660).—20. Repeated evaporation with excess of oxalic acid completely decomposes NaCl to Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub>.

**Combinations.**—1. With water to form hydrates. The dihydrate NaCl.2aq separates from saturated NaClAq cooled to -7° to -22°, in large clear monoclinic crystals (v. Hankel, P. 53, 623; Mitscherlich, J. pr. 83, 485). The crystals effloresce at -10°, and deliquesce at 0°. Ehrenberg (P. 36, 210) and Frankenheim (P. 37, 638) obtained this hydrate by evaporating dilute NaClAq at a moderate temperature. The crystals that separate from hot NaClAq containing HCl are hydrated, according to Bevan (C. N. 35, 17), and contain 5.48 p.c. water, but after a time they change to the ordinary crystals of NaCl. According to Naumann (Thermochemie, 106), crystals of the decahydrate, NaCl.10aq, separate from NaClAq at -23°.—2. NaCl absorbs considerable quantities of ammonia, under pressure. Joannis dissolved NaCl in liquid NH<sub>3</sub> at -10°; on cooling to -30° and letting NH<sub>3</sub> escape at the ordinary pressure, he obtained slender white needles, probably NaCl.5NH<sub>3</sub> (C. R. 112, 337).—3. Sulphuric anhydride is absorbed by NaCl, forming NaCl<sub>2</sub>SO<sub>3</sub>, and then perhaps NaCl<sub>4</sub>SO<sub>3</sub> (v. Reactions, No. 6).—4. Compounds with sodium iodate are formed, by adding excess of NaCl to NaIO<sub>3</sub>Aq, and by boiling NaIO<sub>3</sub> with HClAq, the compound NaCl.NaIO<sub>3</sub>.4aq was obtained by Ditte, and 3NaCl.2NaIO<sub>3</sub>.18aq by Rammelsberg (P. 44, 548; 115, 554).—5. With many chlorides of less positive metals, e.g. AlCl<sub>3</sub>, CdCl<sub>2</sub>, CrCl<sub>3</sub>, PbCl<sub>2</sub>, MgCl<sub>2</sub> (v. Chlorides of various metals).

**Sodium subchloride.** H. Rose (P. 120, 15) noticed that a grey-blue solid was produced by fusing NaCl with Na in H; he thought this might be a subchloride of Na. Bunsen and Kirchhoff (P. 113, 339) noticed the formation of a deep-blue substance during the electrolysis of molten RbCl; this substance dissolved in water, giving off H and producing a colourless, strongly alkaline solution; a similar reaction was obtained on electrolysis KCl; these blue substances were regarded by B. A. K. as probably subchlorides, but no analyses or proofs of composition were given.

**Sodium, chromisulphocyanide of, v. vol. ii. p. 349.**

**Sodium, cyanide of, v. vol. ii. p. 347.**

**Sodium, ferrate of, v. vol. ii. p. 547.**

**Sodium, ferricyanide of, v. vol. ii. p. 340.**

**Sodium, ferrite of, v. vol. ii. p. 547.**

**Sodium, ferrocyanide of, v. vol. ii. p. 337.**

**Sodium, fluoride of, v. vol. i. p. 526.**

**Sodium, fluoride or, NaF.** Mol. w. not known with certainty, but the formula NaF is probably molecular.

**Formation.**—1. By neutralising HFaq by NaOHaq and evaporating.—2. Formed along with NaHSO<sub>4</sub> by the reaction of HFaq with Na<sub>2</sub>SO<sub>4</sub> (Weldon, *D. P. J.* 182, 228).—3. By fusing together CaF<sub>2</sub>, Na<sub>2</sub>SO<sub>4</sub>, and charcoal, and extracting with water (Jean, *C. R.* 66, 801, 918).—4. By boiling powdered cryolite with NaOHaq of at least 1.35 S.G. till a little taken out is entirely sol. boiling water, decanting the alkaline liquid from NaF, pressing the NaF, dissolving in boiling water, separating any Al<sub>2</sub>O<sub>3</sub> in solution by Na<sub>2</sub>SiO<sub>3</sub>Aq, removing silica by CO<sub>2</sub>, filtering, evaporating, and recrystallising the NaF that separates (Schuch, *A.* 126, 108).—5. Berzelius (*Lehrbuch* [5th ed.] 3, 216) prepared NaF by adding to 100 parts Na<sub>2</sub>SiF<sub>6</sub> and 112 parts Na<sub>2</sub>CO<sub>3</sub> water enough to make the whole pasty, boiling as long as CO<sub>2</sub> was given off, extracting the solid thus formed with boiling water, evaporating the solution to dryness, heating the residue gently, again extracting with hot water, filtering from SiO<sub>2</sub>, and crystallising.

**Preparation.**—Pure Na<sub>2</sub>CO<sub>3</sub> (for preparation v. SODIUM CHLORIDE, Preparation, p. 477) is dissolved in pure HFaq, till the acid is just saturated, in a Pt dish, the solution is evaporated to dryness, the residue is heated strongly for some time, and allowed to cool.

**Properties.**—Clear, lustrous cubes; in presence of Na<sub>2</sub>CO<sub>3</sub> crystallises in octahedra. Sl. sol. water; S. at 16° = 4.78 (Berzelius), at 15° = 4 (Fremy, *A. Ch.* [3] 47, 32). Scarcely more sol. hot than cold water. Insol. alcohol. Güntz (*A. Ch.* [6] 3, 5) gives [NaF, Aq] = -600. Decrepitates on heating, and melts at a high temperature without decomposition (Berzelius).

**Reactions.**—1. Partially decomposed by heating to redness in water vapour, with formation of NaOH and HF (Weldon).—2. Excess of caustic potash forms NaOHaq.—3. Boiling with magnesia partially decomposes NaF to NaOHaq and forms a double Na-Mg fluoride (MgF<sub>2</sub>.2NaF) (Tissier, *C. R.* 56, 848).—4. Completely decomposed to NaCl by heating strongly in hydrochloric acid gas (Deville, *C. R.* 43, 970).—5. Partially decomposed to NaCl by heating with ammonium chloride (Rose, *P.* 74, 579). Fusion with magnesium chloride produces NaCl and MgF<sub>2</sub> (Geuther, *J. Z.* 2, 208).

**Combinations.**—1. With several fluorides of less positive metals; 3NaF.AlF<sub>3</sub> occurs native as cryolite (v. ALUMINIUM FLUORIDE, vol. i. p. 145).—2. With silicon fluoride to form Na<sub>2</sub>SiF<sub>6</sub> (v. SODIUM SILICOFLUORIDE, p. 438).—3. With sodium borate to form 6NaF.Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> (v. FLUOBORATES, vol. i. p. 530).—4. With sodium phosphate to form NaF.2Na<sub>2</sub>PO<sub>4</sub>. 19aq and 22aq, and NaF.Na<sub>2</sub>PO<sub>4</sub>. 24aq (v. Baumgarten, *J.* 1865, 219; Briegleb, *A.* 117, 95).—5. With sodium sulphate to form NaF.Na<sub>2</sub>SO<sub>4</sub> (v. Marignac, *Ann. M.* [5] 12, 18).

**SODIUM-HYDROGEN FLUORIDE NaHF<sub>2</sub> or NaF.HF.** This compound is formed, according to Berzelius (*Lehrbuch* [5th ed.] 3, 217), by the spontaneous evaporation of a solution of NaF in HFaq. Forms small rhombohedral crystals,

with a sharp, acid taste. Sl. sol. cold water, more sol. hot water. Decomposed by heat to NaF and HF (Marignac, *J.* 1857, 123). Güntz (*A. Ch.* [6] 3, 5) gives [NaF.HF] = 17,100 (to form NaF.HF).

**Sodium, hydride of, Na<sub>2</sub>H.** Gay-Lussac and Thénard (*A. Ch.* 74, 203) observed that Na absorbed H when heated therein. The process was more accurately studied by Troost and Hautesenille (*A. Ch.* [5] 2, 273). They found that absorption of H by Na began at c. 300° and ceased at c. 421°, when the gas was at the atmospheric pressure. The product gave, in a Sprengel pump, 237 vols. H. for 1 vol. Na; the formula Na<sub>2</sub>H requires 238 vols. H. Na<sub>2</sub>H is a soft, silver-white solid; it can be melted without decomposition in H<sub>2</sub>; S.G. .959. Traces of H are given off at 760 mm. pressure; heated *in vacuo* a regular dissociation takes place from 330° to 430° (for vapour-pressures of H given off v. DISSOCIATION, vol. ii. p. 398). Moutier (*C. R.* 79, 1242) gives the thermal value [Na<sub>2</sub>H] = 13,000 at c. 330°.

**Sodium, hydrosulphide of, NaSH. (Sodium sulphhydrate.)** Sabatier (*A. Ch.* [5] 22, 5) obtained this compound by treating Na<sub>2</sub>S.9aq with H<sub>2</sub>S in absence of air, and then evaporating the liquid so formed in an atmosphere of H<sub>2</sub>S. A white, very hygroscopic solid. Passage of CO into NaSHAq drives out H<sub>2</sub>S and converts all the Na into Na<sub>2</sub>CO<sub>3</sub>. NaSHAq contains H<sub>2</sub>S and NaOH, according to Gernez (*C. R.* 64, 86). NaSHAq dissolves S with evolution of H<sub>2</sub>S; it ppts. PbS, or MnS, from a neutral solution of a Pb or Mn salt, giving off H<sub>2</sub>S; Na<sub>2</sub>SAq does not give off H<sub>2</sub>S while dissolving S or ppg. PbS or MnS.

Sabatier (*l.c.*) obtained the *hydrate* NaSH.2H<sub>2</sub>O by passing H<sub>2</sub>S over Na<sub>2</sub>S.9aq, and then evaporating in H<sub>2</sub>S till half the water was removed; very hygroscopic needles, becoming yellow in air.

**Sodium, hydroxide of, NaOH. (Caustic soda Sodium, or sodic, hydrate.)** Mol. w. not determined. Melts at 1098° (v. Meyer a. Riddle, *B.* 26, 2443). S.G. 2.13 (Filhol, *A. Ch.* [3] 21, 415) 1.723 (Smith, *Am. J. Pharm.* 53, 145). S. (cool water) c. 212 (Bineau, *C. R.* 41, 509). HF [Na.O.H] = 101,870; [Na.O.H.Aq] = 111,810 [Na<sub>2</sub>O.H<sub>2</sub>O] = 35,620 (*Th.* 3, 232).

**Formation.**—1. By the interaction of Na, or Na<sub>2</sub>O, with H<sub>2</sub>O.—2. By decomposing Na<sub>2</sub>CO<sub>3</sub>.Aq with CaO.H<sub>2</sub> (v. Preparation, No. 1).—3. By the action of CaO.H<sub>2</sub> with NaFAq (Tissier *J. pr.* 90, 50).—4. By decomposing Na<sub>2</sub>SO<sub>4</sub>.Aq by BaO or CaO under pressure.—5. From NaClAq by interaction with PbO (Knab, *B.* 11, 1458).—6. By heating NaNO<sub>3</sub> with charcoal, or with Cu (Wöhler, *A.* 87, 373), or Fe (Polacci, *C. N.* 26, 288).—7. By decomposing Na<sub>2</sub>SAq by CuO, Fe<sub>2</sub>O<sub>3</sub>, PbO, ZnO, &c. (Kopp *D. P. J.* 142, 341; Stromeyer, *A.* 107, 333).—8. By the interaction of NaF and steam (Weldon).—9. By heating soda felspar with lime.

**Preparation.**—1. By causticising soda crystals by lime. A solution of pure Na<sub>2</sub>CO<sub>3</sub> crystal in 4-5 parts water is boiled, in a dish of silver or polished iron, with milk of lime till a little of the filtered liquid gives off no CO<sub>2</sub> when acidified; the weight of CaO required is c. the wt. of soda crystals used, it should be

# SODIUM HYDROXIDE

suspended in about as much water as the wt. of soda crystals used; as the boiling proceeds a little water should be added from time to time, otherwise the NaOHAq will decompose some of the CaCO<sub>3</sub> formed to CaO and Na<sub>2</sub>CO<sub>3</sub>Aq. The CaCO<sub>3</sub> formed is allowed to settle, the vessel being closed, the NaOHAq is drawn off by a siphon and evaporated to dryness in a silver dish, and the residue is heated till volatilisation begins, and allowed to cool in an exsiccator. By dissolving in absolute alcohol, allowing to settle, drawing off the liquid, evaporating it to dryness on a water-bath in a silver dish, removing resinous matter from the warm semi-solid mass by a silver spatula, heating to bright redness, and pouring the molten mass on to a plate of polished iron—or, better, of silver—NaOH containing only traces of impurities, chiefly NaCl and Na<sub>2</sub>CO<sub>3</sub>, is obtained.—2. A large silver dish is surrounded by cold water; 2 or 3 drops of water are placed in the dish, and then a small piece of clean Na, 1 or 2 cms. long; the dish is constantly shaken, so that the Na flows over a large cold surface (explosions are thus avoided); when the reaction is finished 2 or 3 more drops of water are added, and then another piece of Na, while the dish is shaken, and so on. The semi-solid mass is heated till the water is all driven off and the NaOH melts, and the molten substance is poured on to a plate of polished iron or silver.

To obtain NaOH free from nitrites and nitrates Ilosva (*Bt.* [3] 2, 357) recommends to place Na in water with a layer of petroleum on the surface, the petroleum having been washed with water till free from nitrites and nitrates. He also says that if 2-4 p.c. ordinary NaOHAq is kept for some weeks in contact with granulated Zn all nitrites and nitrates are destroyed.

For preparation of ordinary caustic soda v. DICTIONARY OF APPLIED CHEMISTRY, vol. iii. p. 480.

**Properties.**—NaOH is a white, hard, brittle solid. Melts below red heat; volatilises at very bright red heat, higher than temperature of volatilisation of KOH. Very deliquescent; dissolves in c. 47 parts water. During solution in water much heat is produced, [NaOHAq] = 9.940 (*Th.* 3, 232); the maximum amount of heat is produced when H<sub>2</sub>O is added to NaOH in the ratio NaOH : 20H<sub>2</sub>O, addition of water to this solution is attended with a slight disappearance of heat (*Th.* 3, 84). (For hydrates v. p. 480, **Combinations.**) Easily sol. alcohol. NaOHAq with 86.86 p.c. NaOH boils at 130°, with 70 p.c. boils 180°, with 77.5 p.c. boils 238°, with 78.7 p.c. boils 243°, and with 82.6 p.c. boils 260° (*Lunge, Soda-industrie*, 2, 543).

NaOHAq acts as a strong alkali; its affinity is c. equal to that of KOHAq and LiOHAq and c. 50 times greater than NH<sub>4</sub>Aq (Ostwald). The properties of NaOHAq closely resemble those of potassium hydroxide solution (*q. v.* p. 302).

The table in the next column, given by Lunge, shows the composition of NaOHAq of different S.G. at 15°.

Regarding the freezing-points of NaOHAq of different concentrations v. Rüdorff (*P.* 116, 55); de Coppet (*A. Ch.* [4] 24, 551); and Pickering (who gives very complete data) *C. J.* 68, 890).

**Reactions.**—1. According to Deville (*C. R.* 45, 857), NaOH is decomposed to Na, O, and H<sub>2</sub> by heating to white heat in an iron bottle.—2. Strongly heated with non-volatile acidic anhydrides, water and salts of Na are formed.—3. When molten NaOH is exposed for a considerable time to air or oxygen, some Na<sub>2</sub>O<sub>2</sub> is formed (Gay-Lussac; Thénard).—4. Moist or molten NaOH is decomposed by electrolysis, with production of Na (Davy, *T.* 1802. 1).—5. Heating with sulphur produces polysulphides, sulphite, and sulphate; S heated with NaOHAq forms polysulphides and sulphite. Similar reactions occur by heating with selenium or tellurium.—6. Chlorine interacts with NaOHAq to

from sodium and iodine, on heating  $\text{NaClO}_4\text{Aq}$  is formed. Bromine reacts similarly. If Cl is led into  $\text{NaOHAq}$  containing iodine in suspension,  $\text{NaIO}_3$  is produced.—7. When  $\text{NaOHAq}$  is warmed with phosphorus, H and inflammable P hydride are given off.—8. Heated with sodium,  $\text{Na}_2\text{O}$  and H are formed.—9. Moist  $\text{NaOH}$  withdraws carbon dioxide from the air, forming  $\text{NaHCO}_3$ .—10. Reacts with acids to form Na salts.—11.  $\text{NaOHAq}$  ppt. metallic hydroxides, or oxides, from solutions of many metallic salts; in some cases the hydroxide dissolves in excess of  $\text{NaOHAq}$ —e.g.  $\text{AlO}_2\text{H}_3$ ,  $\text{ZnO}_2\text{H}_2$ .—12. Molten  $\text{NaOH}$  acts generally as an oxidiser; e.g. As, Sb, Fe, Pt, &c. form arsenate, antimonate, ferrate, and platinate of Na. Salts are generally decomposed by molten  $\text{NaOH}$ , giving Na salts, and setting free the bases.—13. According to Schöne (A. 193, 241), addition of hydrogen peroxide to  $\text{NaOHAq}$  produces  $\text{Na}_2\text{O}_2 \cdot 8\text{H}_2\text{O}$  (v. SODIUM DIOXIDE, p. 482).

Pickering (*priv. comm.*) gives the following data:—

P.c. NaOH	S.G. NaClAq at 16° (water at 4° = 1)	P.c. NaOH	S.G. NaClAq at 15° (water at 4° = 1)	P.c. NaOH	S.G. NaClAq at 15° (water at 4° = 1)

16	1.177619	33	1.362991	50	1.530282

**Combinations.**—1. With water to form hydrates. The hydrate  $2\text{NaOH} \cdot 7\text{H}_2\text{O}$  was obtained by Hermes (B. 3, 122) by exposing  $\text{NaOHAq}$  S.G. 1.365 to the cold of a severe winter; monoclinic crystals, S.G. 1.405, melting at 6°; *in vacuo* gave off  $3\text{H}_2\text{O}$ . Götting (B. 20, 513) obtained a dihydrate,  $\text{NaOH} \cdot 2\text{H}_2\text{O}$ , by heating  $\text{NaOH}$  in 96.8 p.c. alcohol very gradually to 100°. By cooling  $\text{NaOHAq}$ , Pickering (C. J. 63, 890) obtained the following hydrates, with the freezing-points noted:—

Hydrate	Freezing-point
$\text{NaOH} \cdot \text{H}_2\text{O}$	64.3°
$\text{NaOH} \cdot 2\text{H}_2\text{O}$	12.5
$\text{NaOH} \cdot 3.11\text{H}_2\text{O}$ (sic)	2.73
$\text{NaOH} \cdot 3.5\text{H}_2\text{O}$	15.55
$\alpha\text{NaOH} \cdot 4\text{H}_2\text{O}$	7.57
$\beta\text{NaOH} \cdot 4\text{H}_2\text{O}$	— 1.7
$\text{NaOH} \cdot 5\text{H}_2\text{O}$	—12.22
$\text{NaOH} \cdot 7\text{H}_2\text{O}$	—23.51

2. With carbon dioxide to form  $\text{NaHCO}_3$ . Sodium iodide of,  $\text{NaI}$ . Mol. w. not known with certainty, but formula  $\text{NaI}$  is probably Vol. IV.

molecular. Melts at 628° (Carnelley, C. J. 33, 278); at 650° (V. Meyer a. Riddle, B. 26, 2443). S.G. 3.45 (Filhol, A. Ch. [3] 21, 415); 3.654 at 18.2° (Favre a. Valson, C. R. 77, 579). S.H. (26° to 50°) .0881 (Schuler, P. 136, 70); (16° to 99°) .08684 (Regnault, A. Ch. [3] 1, 129). Kremers (P. 108, 120) gives the following data for solubility in water:—

Temp.	S.	Temp.	S.
0°	158.7	80°	303
20	178.6	100	312.5
40	208.4	120	322.5
60	256.4	140	333.3

S. =  $264.19 + 3978t$ , when  $t$  varies from 64.7° to 138.7° (de Coppet, A. Ch. [5] 80, 411). Gerlach (Fr. 8, 285) gives following:—

S.G. NaIAq	P.C. NaI	S.G. NaIAq	P.C. NaI
1.04	5	1.36	35
1.032	10	1.33	40
1.128	12	1.51	45
1.179	20	1.6	50
1.234	25	1.7	55
1.294	30	1.81	60

Easily sol. alcohol. Saturated  $\text{NaIAq}$  boils at 141.1°. H.F.  $[\text{Na}, \text{I}] = 69,080$ ;  $[\text{Na}, \text{I}, \text{Aq}] = 70,800$  (Th. 8, 232).

**Formation.**—1. When Na and I are fused together only very small quantities combine (Merz a. Weith, B. 6, 1518).—2. By decomposing  $\text{BaIAq}$ , or  $\text{CaIAq}$ , by  $\text{Na}_2\text{CO}_3$  or  $\text{Na}_2\text{SO}_4$ , filtering, and evaporating.—3. By neutralising  $\text{HIAq}$  by  $\text{Na}_2\text{CO}_3$ , and evaporating.—4. I is added to water and iron filings till the iron is almost all dissolved, the solution is filtered, and  $\text{Na}_2\text{CO}_3$  is added so long as  $\text{FeCO}_3$  ppts.; the liquid is filtered (if alkaline it is neutralised by  $\text{HIAq}$ ) and evaporated, any  $\text{Fe}_2\text{O}_3$  which separates being filtered off (Baup, J. Ph. 9, 37, 122).

**Preparation.**—1. Iodine is added to moderately conc.  $\text{NaOHAq}$  till a yellow colour is produced; finely-powdered charcoal, equal to c.  $\frac{1}{10}$  of the weight of I used, is added; the liquid is evaporated to dryness and the residue is heated in a covered crucible to dull redness for some time; when cold, the residue is dissolved in water, the liquid is filtered (neutralised by  $\text{HIAq}$  if alkaline) and crystallised at 40°–50°. (For more details v. POTASSIUM IODIDE, Preparation, p. 304).—2. A quantity of  $\text{NaOHAq}$  is divided into two equal portions; I is added to one part till a yellow colour remains, an equal quantity of I is then added, and then the other portion of  $\text{NaOHAq}$  is saturated with  $\text{SO}_2$  and added, and the whole is evaporated till  $\text{NaI}$  crystallises out; the salt is purified by recrystallisation from water at 40°–50° (Stephani, J. Ph. [3] 26, 450).

**Properties.**—Crystallises from aqueous solutions at 40° to 50° in cubes (Mitscherlich, P. 17, 385); the hydrate  $\text{NaI} \cdot 2\text{aq}$  separates at ordinary temperatures. Melts at 623°; volatilises less readily than  $\text{KI}$ , but at a lower temperature than  $\text{NaCl}$  (Mohr, A. 21, 66). Deliquesces in moist air, becoming rose-coloured with separation of some I and formation of some  $\text{Na}_2\text{CO}_3$  (Girault, J. Ph. 27, 390).

**Reactions and Combinations.**—1. Heated in air some I is separated and O absorbed, and the reaction becomes alkaline (Berzelius, Lehrbuch II

[5th ed.] 3, 215).—2. *Heated with charcoal in contact with air* much  $\text{Na}_2\text{CO}_3$  is formed (Girault, l.c.). Most of the reactions of NaI are similar to those of KI (v. POTASSIUM IODIDE, *Reactions*, p. 304).

Combines with most *iodides of less positive metals*. Forms a compound with *arsenious oxide*  $\text{NaI}.\text{As}_2\text{O}_3$  (Rüdorff, B. 21, 3051). The *dihydrate*  $\text{NaI} \cdot 2\text{H}_2\text{O}$  crystallises at the ordinary temperature from NaIAq in large monoclinic prisms; S.G. 2.448; melting at c.  $65^\circ$  and giving NaI; effloresces in dry air, and deliquesces in moist air.

**Sodium, manganicyanide of**, v. vol. ii. p. 342.

**Sodium, manganocyanide of**, v. vol. ii. p. 342.

**Sodium, nitride of**,  $\text{Na}_3\text{N}$ . A dark-grey solid; formed by heating  $\text{NaNH}_2$  (v. SODIUM AMIDE, p. 475) to redness in absence of O. Resembles *potassium nitride* (q. v., p. 304) (Gay-Lussac & Thénard, A. Ch. 65, 325).

**Sodium, nitroprusside of**, v. vol. ii. p. 341.

**Sodium, oxides of**. Two oxides have been isolated,  $\text{Na}_2\text{O}$  and  $\text{Na}_2\text{O}_2$ .

**SODIUM OXIDE**  $\text{Na}_2\text{O}$ . (*Sodium monoxide*.) It is doubtful whether this compound has been obtained pure. Davy (T. 1808. 24) said that when Na is fused with dry soda there is 'a division of the oxygen between the alkali and the sodium.' Na does not combine with O when exposed to quite dry air at the ordinary temperature (von Bonsdorff, P. 41, 296). According to Beketoff (v. B. 12, 856; 16, 1854),  $\text{NaOH}$  and Na do not react at a red heat. Beketoff (J. R. 1883. [i.] 277 [v. B. 16, 1854]) allowed Na to drop into a red-hot copper cylinder, then passed in a mixture of 1 vol. O and 4 vols. air, and heated by a blowpipe; in this way he obtained  $\text{Na}_2\text{O}$ , but always mixed with some Cu and traces of Na; considering the conditions under which  $\text{Na}_2\text{O}_2$  is obtained (v. *infra*, *Sodium dioxide*) it is likely that B.'s  $\text{Na}_2\text{O}$  contained  $\text{Na}_2\text{O}_2$ .

$\text{Na}_2\text{O}$  is described as a greyish solid; Beketoff's preparation was rose-coloured, but it contained Cu.  $\text{Na}_2\text{O}$  dissolves in water to form  $\text{NaOH}$ Aq; B. gives  $[\text{Na}^+\text{O}.\text{Aq}] = 55,500$ ; and from this and other data Thomsen (Th. 3, 232) calculates  $[\text{Na}^+\text{O}] = 99,760$ . According to B. (l.c.), hot  $\text{Na}_2\text{O}$  reacts with H to form  $\text{NaOH}$  and Na; heated to c.  $300^\circ$  in CO it gives  $\text{Na}_2\text{CO}_3$  and Na (B., l.c.). Combination with  $\text{CO}_2$  to form  $\text{Na}_2\text{CO}_3$ , occurs at c.  $400^\circ$ . By heating Na amalgam with  $\text{HgO}$ , B. (l.c.) obtained the compound  $\text{Na}_2\text{HgO}_2 = \text{Na}_2\text{O}.\text{HgO}$ . Comey and Jackson (B. 21, 1589; Am. 11, 145) describe various compounds of  $\text{Na}_2\text{O}$  with  $\text{ZnO}$  and  $\text{H}_2\text{O}$ .

**SODIUM DIOXIDE**  $\text{Na}_2\text{O}_2$ . (*Sodium peroxide*.) The formation of an oxide with more O than  $\text{Na}_2\text{O}$ , by heating Na in air, was noticed by Gay-Lussac & Thénard (A. Ch. 65, 325). Pure  $\text{Na}_2\text{O}_2$  was obtained by Vernon Harcourt (C. J. 14, 267) by heating Na, in a flask of hard glass filled with N, till the Na melted, then sending in a slow stream of dry air, and heating till the metal was changed to a yellowish-white solid, and heating this for some time in dry O.  $\text{Na}_2\text{O}_2$  is a white solid, becoming yellowish on heating. It deliquesces gradually in air, and then is gradually changed into solid  $\text{Na}_2\text{CO}_3$ . Soluble water,

with production of much heat; on heating O is evolved;  $\text{Na}_2\text{O}_2$ Aq deposits crystals of the hydrate  $\text{Na}_2\text{O}_2 \cdot 8\text{H}_2\text{O}$  on standing over  $\text{H}_2\text{SO}_4$  (v. *infra*, *Hydrates*).  $\text{Na}_2\text{O}_2$  acts as an energetic oxidiser when heated; C, I, P, S, Sn are oxidised, more or less rapidly; heated with CO,  $\text{Na}_2\text{CO}_3$  is formed; with  $\text{N}_2\text{O}$  the products are  $\text{NaNO}_2$  and N (v. Harcourt, l.c.).

**Hydrates of sodium dioxide**. The *octohydrate*,  $\text{Na}_2\text{O}_2 \cdot 8\text{H}_2\text{O}$ , was obtained by Harcourt (l.c.) by evaporating a solution of  $\text{Na}_2\text{O}_2$  in water over  $\text{H}_2\text{SO}_4$ . Fairley (C. J. [2] 16, 125) obtained the same hydrate by adding  $\text{H}_2\text{O}_2$ Aq to  $\text{NaOH}$ Aq and ppg. by alcohol. Schöne (A. 193, 241) also obtained the octohydrate by the action of  $\text{H}_2\text{O}_2$ Aq on  $\text{NaOH}$ Aq, evaporating *in vacuo*, drying on a porous tile, washing with 90 p.c. alcohol, and drying between filter paper. By using a considerable excess of  $\text{H}_2\text{O}_2$ Aq, Schöne (l.c.) obtained crystals to which he gave the composition  $\text{Na}_2\text{H}_2\text{O}_2 \cdot 4\text{H}_2\text{O} = \text{Na}_2\text{O}_2 \cdot 2\text{H}_2\text{O} \cdot 4\text{H}_2\text{O}$ ; on drying over  $\text{H}_2\text{SO}_4$ ,  $\text{Na}_2\text{O}_2 \cdot 2\text{H}_2\text{O}$  remained. The *dihydrate*  $\text{Na}_2\text{O}_2 \cdot 2\text{H}_2\text{O}$  is obtained by drying the octohydrate for some time over  $\text{H}_2\text{SO}_4$ .

**Sodium, phosphide of**. A compound of Na and P was supposed by Gay-Lussac & Thénard, and also by Davy, to be formed by heating the elements together in N. Vigier (Bl. [2] 3, 7) recommends to place a piece of Na in rock oil, boiling at c.  $120^\circ$ , in a retort, to add P little by little (much heat is produced and some oil distils) till there is an excess and some crystallises on the cold parts of the retort, to distil off the oil from the black phosphide formed, to wash with  $\text{CS}_2$ , and dry in a stream of  $\text{CO}_2$ .

The phosphide may be kept in dry air; in moist air, water, or acids it gives off inflammable P hydride (v. also Lüpke, C. C. 1890. [ii.] 642).

Bunsen (A. 138, 292) obtained a phosphide of Na by strongly heating a mixture of  $\text{Na}_2\text{HPO}_4$  and Na in a narrow glass tube.

**Sodium, platincyanoide of**, v. vol. ii. p. 344.

**Sodium, platinosulphocyanide of**, v. vol. ii. p. 351.

**Sodium, salts of**. *Compounds formed by replacing H of acids by Na*. These compounds belong to the type  $\text{NaX}$  where X is a monovalent acidic radicle. The chief salts of Na derived from oxyacids are *antimonate*, *arsenate*, *bromate* and *hypobromite*, *carbonates*, *chlorate*, *perchlorate*, *chlorite* and *hypochlorite*, *chromate* and *dichromate*, *iodate* and *periodates*, *manganate* and *permanganate*, *molybdates*, *nitrate* and *nitrite*, *phosphates*, *phosphites* and *hypophosphite*, *selenates* and *selenites*, *silicates*, *sulphates*, *sulphites*, *thiosulphate* and *thionates*, *tellurates* and *tellurites* (v. CARBONATES, NITRATES, SULPHATES, &c.).

**Sodium, selenides of**. Two selenides have been isolated,  $\text{Na}_2\text{Se}$  and  $\text{Na}_2\text{Se}_2$ , corresponding with two of the sulphides and with the two oxides.

**SODIUM MONOSELENIDE**  $\text{Na}_2\text{Se}$ . Obtained by mixing well-cleaned Na rubbed to powder with the proper proportion of Se (Rosenfeld, B. 24, 1658). Uelsmann (A. 116, 127) says  $\text{Na}_2\text{Se}$  is obtained, in large colourless crystals, by saturating  $\text{NaOH}$ Aq with  $\text{H}_2\text{Se}$ , then heating in a stream of H and allowing to cool; it seems probable that these crystals were a hydrate of  $\text{Na}_2\text{Se}$  (v.

*infra*). Fabre (U. M. 102, 618) obtained  $\text{Na}_2\text{Se}$  by heating  $2\text{Na}_2\text{Se} \cdot 9\text{H}_2\text{O}$  (*v. infra*, *Hydrates*) in a current of N to not above  $400^\circ$ ; F. describes  $\text{Na}_2\text{Se}$  as a hard, white, crystalline, deliquescent solid, becoming reddish-brown when fused; owing to its action on glass, F. did not get  $\text{Na}_2\text{Se}$  free from silica and alumina.

*Hydrates of sodium monoselenide.* By passing a rapid stream of  $\text{H}_2\text{Se}$  into  $\text{NaOHAq}$  (1 part  $\text{NaOH}$  in 4 water) Fabre (*l.c.*) obtained  $\text{Na}_2\text{Se} \cdot 16\text{H}_2\text{O}$ , melting at  $40^\circ$ , giving  $\text{Na}_2\text{CO}_3$ , a little  $\text{Na}_2\text{SeO}_3$ , and  $\text{Se}$  on exposure to air. By using more conc.  $\text{NaOHAq}$  (3:1), and keeping the temperature down, F. obtained  $\text{Na}_2\text{Se} \cdot 9\text{H}_2\text{O}$ ; and when very conc.  $\text{NaOHAq}$  was used, he obtained  $2\text{Na}_2\text{Se} \cdot 9\text{H}_2\text{O}$ .

For data regarding heats of formation of  $\text{Na}_2\text{Se}$  and hydrates, *v. Fabre, C. R.* 102, 703.

**SODIUM DISULFIDE**  $\text{Na}_2\text{S}_2$ . Wöhler and Dean (A. 97, 1) obtained a selenide of K by heating  $\text{K}_2\text{SeO}_4$  with charcoal; Rathke (A. 152, 211) showed that the selenide was  $\text{K}_2\text{Se}_2$ , and Jackson (B. 7, 1277) using  $\text{Na}_2\text{SeO}_3$  and charcoal obtained the corresponding selenide of sodium.

**Sodium, seleno-antimonate of, v. vol. i. p. 286.**

**Sodium, selenocyanide of, v. vol. ii. p. 348.**

**Sodium, silicofluoride of,  $\text{Na}_2\text{SiF}_6$ .** Prepared by adding  $\text{H}_2\text{SiF}_6\text{aq}$  to conc.  $\text{NaClaq}$ , washing, and drying. Gelatinous when *ppd.*, but becomes crystalline on drying. S.G.  $2.7517$  at  $17.5^\circ$  (Stolba, *Fr.* 11, 199). S.  $65$  at  $17.5^\circ$ ;  $2.46$  at  $100^\circ$  (S., *l.c.*). Insol. alcohol. Melts at red heat, giving off  $\text{SiF}_4$  (Berzelius).

**Sodium, sulphides of.** Several compounds of Na and S exist, but there is considerable doubt as to the compositions of some of the substances that are described as definite sulphides of Na.

**SODIUM MONOSULPHIDE  $\text{Na}_2\text{S}$ .** Obtained by passing  $\text{H}_2\text{S}$  over dry  $\text{NaOH}$ , the heat produced suffices to remove  $\text{H}_2\text{O}$  formed (Kircher, A. 81, 339). Rosenfeld (B. 24, 1658) says that  $\text{Na}_2\text{S}$  is formed when 1 part thoroughly clean Na is rubbed to powder and mixed with 3 parts  $\text{NaCl}$  and 7 part S; the combination is sudden, and light is produced; pressure must be avoided in mixing the substances. By heating 100 to 105 parts  $\text{Na}_2\text{SO}_4$  with 20 parts charcoal, a flesh-coloured mass of  $\text{Na}_2\text{S}$  with some C is obtained; the reduction may also be effected in H. By dissolving the product of reduction in water and crystallising, the hydrate  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  is obtained; by dissolving the crystals again, heating with Cu (to decompose polysulphides), and evaporating to dryness in a stream of H,  $\text{Na}_2\text{S}$  remains (Priwoznik, A. 164, 69).

$\text{Na}_2\text{S}$  is also obtained, fairly pure, by gently heating  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  in a stream of H (Weyl, P. 123, 362; *cf. Sabatier, A. Ch.* [5] 22, 5).

$\text{Na}_2\text{S}$  is an amorphous, flesh-coloured, deliquescent solid, with a strongly alkaline reaction; easily sol. water, solution being colourless if polysulphides are quite absent. According to Weldon (*v. Lunge's Soda-industrie*, 2, 311),  $\text{Na}_2\text{S}$  is not fusible if it be quite free from polysulphides, thiosulphate, and  $\text{NaOH}$ .

$\text{Na}_2\text{SAq}$  becomes yellow in moist air from formation of polysulphides (Kolb, A. Ch. [4] 10, 106); when air is blown into  $\text{Na}_2\text{SAq}$ ,  $\text{NaOH}$

and  $\text{Na}_2\text{S}_2\text{O}_3$  are formed, and then  $\text{Na}_2\text{SO}_3$  (Lunge, *l.c.*, p. 531).  $\text{Na}_2\text{S}$  is decomposed by acids, even by  $\text{CO}_2$  with evolution of  $\text{H}_2\text{S}$  (*v. Stromeyer, A.* 107, 373). Heating  $\text{Na}_2\text{SAq}$  with  $\text{NaHCO}_3$  or  $\text{NH}_4\text{HCO}_3$  produces complete decomposition to  $\text{Na}_2\text{CO}_3$  (Lunge, *l.c.* p. 800). Boiling with  $\text{AlO}_3\text{H}_3$ , or heating  $\text{Na}_2\text{S}$  with  $\text{Al}_2\text{O}_3$ , forms Na aluminate (*v. W. J.* 1863, 713; 1865, 332).  $\text{CaO}$  is said not to decompose  $\text{Na}_2\text{SAq}$  (*v. Kolb, A. Ch.* [4] 10, 106). Several metallic oxides decompose  $\text{Na}_2\text{SAq}$ , forming  $\text{NaOHAq}$ , sometimes (*e.g.* with  $\text{CuO}$ )  $\text{Na}_2\text{S}_2\text{O}_3\text{aq}$  is also formed.  $\text{Na}_2\text{S}$  combines with various metallic sulphides (*v. Schneider, P.* 138, 302; 151, 446; Völcker, A. 59, 35; Berthier, A. Ch. [2] 22, 245).

*Hydrates of sodium monosulphide.* The hydrates  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$ ,  $\text{Na}_2\text{S} \cdot 10\text{H}_2\text{O}$ , and  $\text{Na}_2\text{S} \cdot 5\text{H}_2\text{O}$  have been formed. The hydrate with  $9\text{H}_2\text{O}$  is most easily obtained by saturating one half of a solution of  $\text{NaOH}$  with  $\text{H}_2\text{S}$ , adding the other half, and evaporating, when large colourless crystals separate (Rammelsberg, P. 123, 172); S.G.  $2.471$  (Fihol, A. Ch. [4] 28, 529). The pentahydrate is formed similarly to the hydrate with  $9\text{H}_2\text{O}$ , but using alcoholic in place of aqueous  $\text{NaOH}$  (Böttger, A. 223, 335; *v. also Finger, P.* 123, 635; Lemoine, C. R. 98, 45). For the preparation of  $\text{Na}_2\text{S} \cdot 10\text{H}_2\text{O}$  *v. Damoiseau (C. C.* 1885, 36). Göttig (*J. pr.* [2] 31, 229) by partially saturating  $\text{NaOH}$  in alcohol with  $\text{H}_2\text{S}$  got hydrates with 5, 5½, and 6  $\text{H}_2\text{O}$ .

**SODIUM DISULPHIDE  $\text{Na}_2\text{S}_2$ .** This compound is supposed by Sabatier (A. Ch. [5] 22, 5) to exist in the solution obtained by heating  $\text{Na}_2\text{SAq}$  with solution of polysulphides formed by digesting  $\text{Na}_2\text{SAq}$  with S. Böttger (A. 223, 335) obtained the hydrate  $\text{Na}_2\text{S}_2 \cdot 5\text{H}_2\text{O}$  by dissolving S in an alcoholic solution of  $\text{Na}_2\text{S}$ .

**SODIUM TRISULPHIDE  $\text{Na}_2\text{S}_3$**  is formed, according to Schöne (J. 1867, 190), mixed with  $\text{Na}_2\text{SO}_3$ , by strongly heating  $\text{Na}_2\text{CO}_3$  with excess of S (*cf. Sabatier, l.c.*). For the hydrate  $\text{Na}_2\text{S}_3 \cdot 3\text{H}_2\text{O}$  *v. Böttger (l.c.)*.

**SODIUM TETRASULPHIDE  $\text{Na}_2\text{S}_4$**  is said to be obtained by heating  $\text{Na}_2\text{S}_3$  (Chapman Jones, C. J. 37, 461; *cf. Sabatier, l.c.*). For hydrates *v. Schöne (P.* 131, 380) and Böttger (*l.c.*).

The existence of a *pentasulphide* is doubtful (*v. Schöne, l.c.*; Sabatier, *l.c.*; Geuther, A. 226, 232; Chapman Jones, *l.c.*).

*Soda liver of sulphur.* This name is given to the brown solid obtained by heating S with  $\text{Na}_2\text{CO}_3$  in a closed vessel; it contains various sulphides of Na, along with  $\text{Na}_2\text{S}_2\text{O}_3$ ,  $\text{Na}_2\text{SO}_3$ , and generally some  $\text{Na}_2\text{CO}_3$ .

**Sodium, sulphocyanide of, v. vol. ii. p. 352.**

**Sodium, sulphhydrate of, v. Sodium hydrosulphide, p. 479.**

**SODIUM ETHIDE  $\text{NaC}_2\text{H}_5$ .** This compound is not known in the free state. Sodium dissolves in cold  $\text{ZnEt}_2$ , separating zinc. The solution, cooled to  $0^\circ$ , deposits  $\text{ZnEt} \cdot \text{NaEt}$  in trimetric tables [ $27^\circ$ ], sol. benzene, and decomposed by water.  $\text{CO}_2$  acting on  $\text{ZnEt} \cdot \text{NaEt}$

forms sodium propionate (Wanklyn, A. 107, 125; 108, 67). EtI attacks  $\text{ZnEt}_2\text{NaEt}$ , forming ethane and  $\text{C}_2\text{H}_4$  (Frankland, A. 110, 107). Sodium methide may be obtained in like manner (Wanklyn, A. 111, 234).

**SOJA OIL.** The oil from *Soja hispida* contains tripalmitin and tristearin (Meisel a. Böcker, M. 4, 365).

**SOLANINE**  $\text{C}_{25}\text{H}_{47}\text{NO}_8$  (?) (Firbas, M. 10, 541);  $\text{C}_{25}\text{H}_{47}\text{NO}_{11}$ ;  $\text{C}_{25}\text{H}_{47}\text{NO}_{13}$  (Hilger, A. 195, 317);  $\text{C}_{25}\text{H}_{47}\text{NO}$  (Kletzensky, Z. [2] 2, 127). [244°]. Occurs in the berries of the deadly nightshade (*Solanum nigrum*) (Desfosses, J. Ph. 6, 374), in berries of *S. verbascifolium* (Payen a. Chevallier, J. Chim. Méd. 1, 517), in small quantity in the tubers and green parts of the potato (*S. tuberosum*), in the shoots of sprouting potatoes (Baup, A. Ch. [2] 31, 109; Otto, A. 7, 160; 26, 232), to the extent of .03 p.c. in diseased potatoes (Kassner, Ar. Ph. [3] 25, 402), in the flowers, stalks, and berries of the woody nightshade (*S. Dulcamara*), and in the root of *Scopolia japonica* (Martin, Ar. Ph. [3] 13, 336).

**Preparation.**—1. The berries are pressed, the juice ppd. by ammonia, and the pp. recrystallised from alcohol.—2. Fresh potato sprouts (200 kilos.) are digested with 2 p.c. acetic acid; the filtrate is ppd. by ammonia; and the pp. extracted with boiling 85 p.c. alcohol. To the hot alcoholic filtrate  $\text{NH}_4\text{Aq}$  is added until turbidity appears. On cooling, a mixture (125 g.) of solanine and solanin is deposited. These bases are separated by fractional crystallisation from hot spirit (Firbas; cf. Reuling, A. 80, 225; Zwenger a. Kind, A. 109, 244; 118, 129; Kromayer, Ar. Ph. [2] 116, 114; Missaghi, B. 9, 83; Gmelin, A. 110, 167).

**Properties.**—Colourless needles, v. sol. hot 85 p.c. alcohol, insol.  $\text{HCl}$ , and ligroin, sol.  $\text{HClAq}$ , almost insol. water and ether. The crystals are  $\text{C}_{25}\text{H}_{47}\text{NO}_{11} \cdot 4\frac{1}{2}\text{aq}$  (Firbas). Poisonous. Not affected by alcoholic potash. Sublimes at 190° (Blyth). Gives an orange colour with I and  $\text{H}_2\text{SO}_4$ . On heating with 2 p.c.  $\text{HClAq}$  it yields solanidine and a dextro-rotatory sugar that reduces Fehling's solution,  $[\alpha]_D = 28.6^\circ$ , yields with phenyl hydrazine an osazone [199°], and is oxidised by  $\text{HNO}_3$  to mucic and saccharic acids; levulose is not present. Solanine colours a mixture of alcohol and  $\text{H}_2\text{SO}_4$  rose red. With ammonium selenite (1 g.) in conc.  $\text{H}_2\text{SO}_4$  (20 c.c.) it gives a canary-yellow colour turning to brown, and, after three hours, to violet-red (Ferreira da Silva, Bl. [3] 6, 87; C. R. 112, 1267). A solution of ammonium vanadate in  $\text{H}_2\text{SO}_4$  is coloured brown by dry solanine, the colour becoming red, and finally disappearing on dilution (Mandelin).

**Salts.**— $\text{C}_{25}\text{H}_{47}\text{NO}_8 \cdot \text{HCl}$ . Got by adding ether to an alcoholic solution of the base and  $\text{HCl}$ . Gelatinous pp. which dries up to a gummy mass.— $\text{B}'\text{H}_2\text{PtCl}_6$ : yellow flocculent pp.— $\text{B}'\text{H}_2\text{SO}_4$ : amorphous, v. sol. water.— $\text{B}'\text{H}_2\text{C}_2\text{O}_7$ : crystalline crusts.

**Acetyl derivative**  $\text{C}_{25}\text{H}_{45}\text{AcO}_8\text{NO}_{11}$ . Needles (from ether), insol. water (Hilger).

**Solanin**  $\text{C}_{25}\text{H}_{47}\text{NO}_{11}$ , 4aq. [208°]. Obtained as above (Firbas). Amorphous. More sol. 85 p.c. alcohol than solanine. Decomposed by  $\text{HClAq}$  into the same products as solanine. Colours Mandelin's reagent red,

**Solanidine**  $\text{C}_{25}\text{H}_{47}\text{NO}$  [191°]. Formed as above. Colourless needles (from ether). Affects Mandelin's reagent in the same way as solanin.  $\text{Ac}_2\text{O}$  at 140° gives a diacetyl derivative (Firbas). Converted by fuming  $\text{HClAq}$  in the cold into amorphous yellow solanidine  $\text{C}_{25}\text{H}_{47}\text{NO}$  (?), which yields  $\text{B}'\text{HCl}$  and  $\text{B}'\text{H}_2\text{PtCl}_6$  (Zwenger, A. 123, 241).

**Salts.**— $\text{B}'\text{HCl}$ , aq: crystalline powder.— $\text{B}'\text{H}_2\text{HSO}_4$ , 8aq: colourless plates [247°].

**SOLUTIONS.** Inasmuch as many of the questions connected with the state of bodies in solution are not yet fully elucidated, and inasmuch as two very different conceptions are put forward regarding the compositions of bodies present in aqueous solutions of salts, the editor of that portion of the Dictionary to which the subject of solutions belongs thought it advisable to ask the originator of the electrolytic dissociation hypothesis of saline solutions to write a short article on solutions in general, and to invite one of the leading upholders of the hydrate hypothesis of saline solutions to summarise the arguments in support of that hypothesis.

**SOLUTIONS I.** A solution is a homogeneous mixture of two or more bodies in the liquid state. A distinction is made between the dissolved substance and the solvent; the substance present in greater quantity is generally spoken of as the solvent. In some cases the solvent is taken to be the substance with the lower temperature of solidification. In the cases of substances miscible in all proportions—a mixture, for instance, of equal parts of alcohol and water—there is no way of determining which should be regarded as the solvent and which as the dissolved substance. There are many instances of two bodies that cannot be mixed in all and any proportions; the solubility of such bodies is said to be *limited*. If the 'dissolved body' in such a case is present in excess, either as gas, liquid, or solid, a condition of equilibrium is finally attained wherein the solution can take up no more of the dissolved body as long as the external conditions (temperature and pressure) remain unchanged; such a solution is said to be *saturated*. The attainment of saturation is hastened by shaking.

**Saturated solutions of gases.** When a gas is placed over a liquid, such as water or alcohol, a portion of the gas dissolves in the liquid. There is a constant relation at constant temperature between the quantity of gas remaining per unit volume and the quantity dissolved by the liquid per unit volume (Henry's law). Inasmuch as the quantity of the gas, per unit volume, is proportional to the partial pressure of the gas, the law may be stated by saying that the quantity of the gas dissolved in the liquid is proportional to the partial pressure of the gas above the liquid. As all the gases that have been examined dissolve with production of considerable quantities of heat, the solubilities of these gases decrease as temperature increases, in accordance with the second law of thermodynamics. The measurements made by Bunsen (*Gasom. Methoden* [Braunschweig, 1877]) show that the solubilities of some gases are independent of temperature—for instance, the solubility of H in water and of O and CO in alcohol. Henry's law holds good, as indicated by theory, only so long as the quantity of the gas per unit volume, both undissolved

and in solution, is small, and the molecules of the dissolved and the undissolved gas are of equal magnitude. Van't Hoff has made use of the law of Henry to prove the equality of the molecules of the same gas in the gaseous state and in dilute solution (*Z. P. C.* 1, 489 [1877]). When  $\text{NH}_3$ ,  $\text{HCl}$ , and  $\text{SO}_2$  are dissolved in water in large quantities these gases do not follow the

temperature, which corresponds to the critical temperature for the liquids, is passed, the two liquids dissolve in all proportions. This behaviour has been more fully examined by Alexejff (*W.* 28, 305 [1886]) and has been represented by him in curves, some of which are reproduced here (fig. 1). The curve *a* represents the behaviour of water and phenol, *b* that of water

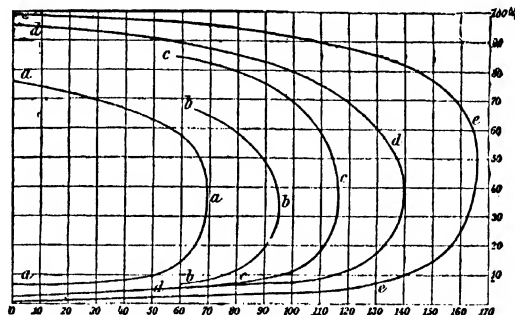

FIG. 1.

law of Henry; neither does the law hold good for solutions of acetic acid in benzene or ether in water, because the molecular magnitudes of these compounds are not the same in the gaseous state and in solution, as is proved by determinations of the boiling-points of the compounds in question (Nernst, *Z. P. C.* 7, 97 [1891]).

*Mutual solutions of liquids.* When two liquids that are not miscible in all proportions,

and salicylic acid, *c* that of water and benzoic acid, *d* that of water and aniline phenolate, and *e* that of water and aniline. The abscissae represent temperature, and the ordinates percentages of the dissolved substances in the solutions. To each temperature correspond two points in the curve showing the percentage composition of the solution of the substance in water, and that of the solution of water in the molten sub-

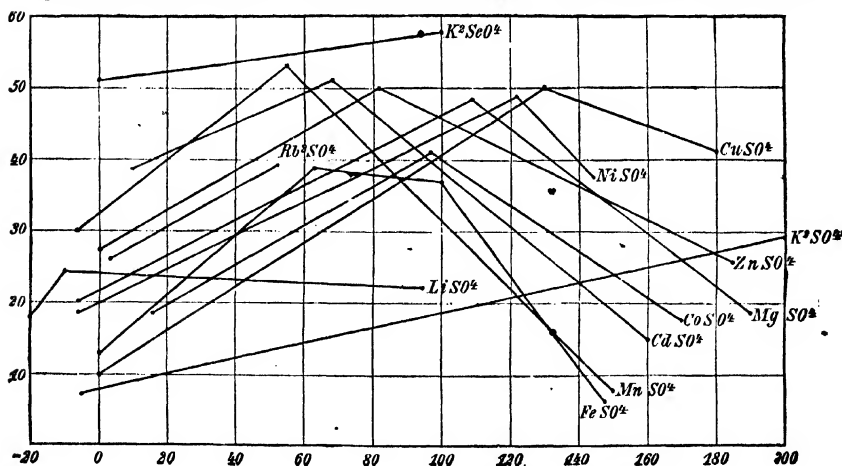

FIG. 2.

such as ether and water, are shaken together, two layers are formed, one floating on the other; one of these contains much water and little ether, while the other contains much ether and little water. The compositions of the two layers change with change of temperature. Generally speaking, the compositions become more alike as temperature rises, until a temperature is reached whereat they are identical; when this

stance; thus, for phenol and water (curve *a*), at 20°, the solutions are composed of 92.5 p.c. water and 7.5 p.c. phenol, and 28 p.c. water and 72 p.c. phenol respectively. The two liquids are miscible in all proportions above 69°.

It happens sometimes that two liquids are miscible in all proportions below a certain temperature, but form two layers above this temperature; in such cases—for example, in the

solution of di-ethylamine in water—the convexity of the curve is turned to the left.

*Saturated solutions of solids.* Most of the measurements that have been made deal with solutions of salts in water. The example of Gay-Lussac has generally been followed, and the solubility of the salt has been taken as the weight thereof dissolved by 100 parts by weight of the solvent. Etard and Engel have given solubility-curves for very large variations of temperature (*C. R.* 98, 993, 1276, 1432; 104, 1614; 106, 206, 740 [1884-88]). Some of these results are shown in fig. 2, p. 485; the abscissæ represent temperature and the ordinates parts by weight of the salts in 100 parts of the solution (not in 100 parts of the solvent). The change of solubility with change of temperature depends on whether the process of solution is accompanied by disappearance or production of heat; in the former case solubility increases, in the latter case it decreases, as temperature rises. Inasmuch as different hydrates of the same salt are dissolved with the production of different quantities of heat, these hydrates give different solubility-curves. Sodium sulphate is the salt that has been most carefully examined in this respect. The hydrate  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ , that exists up to  $33^\circ$ , dissolves in water with disappearance of heat; hence the solubility of this hydrate increases as temperature increases. On the other hand,  $\text{Na}_2\text{SO}_4$ , stable above  $33^\circ$ , dissolves with production of heat, and its solubility decreases with increasing temperature. The so-called curve of the solubility of sodium sulphate consists, therefore, of two parts, one rising till the temperature reaches  $33^\circ$ , and one falling above that temperature. Looked at accurately, the first part of the solubility-curve holds good only for  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ , and the second part only for  $\text{Na}_2\text{SO}_4$ . For the solubility of a chemical compound is determined only when the composition of the solid compound that is in contact with the solution is definitely stated. The compound  $\text{CaSO}_4$  is considerably more soluble than the crystalline hydrate  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ . The measurements made by Etard show that many other sulphates— $\text{MnSO}_4$  and  $\text{CdSO}_4$ , for instance—behave similarly to  $\text{Na}_2\text{SO}_4$  (see fig. 2).

The solubilities of most salts increase as temperature rises; the solubility of  $\text{NaCl}$  varies very little with temperature. The solubilities of many compounds of calcium decrease with increasing temperature, *e.g.* hydroxide, acetate, iso-valerate, isobutyrate, succinate, and iso-succinate of calcium. Barium succinate and  $\text{SrSO}_4$  behave similarly, but not the other corresponding salts of Ba and Sr. Some calcium salts show maximum solubilities at certain temperatures—*e.g.*  $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$  at  $35^\circ$ ; others show minimum solubilities—*e.g.* propionate at *c.*  $55^\circ$ , isobutyrate at  $65^\circ$ , also normal butyrate, valerate, iso-octoate, citrate, and benzoate (Allen, *C. N.* 57, 236 [1888]). Attempts have been made to express the connection between the solubilities of salts and temperature by a formula. The following expression holds good in many cases:  $S = a + bt$  ( $t$  = temperature, and  $a$  and  $b$  are constants); *i.e.* solubility changes linearly with temperature—for instance, for  $\text{KCl}$ ,  $\text{BaCl}_2$ ,  $\text{NaNO}_3$ , and several sulphates, especially at high temperatures (Etard). In other cases it is necessary to

add a third term to the formula, and to adopt the formula  $S = a + bt + ct^2 + dt^3$  ( $c$  and  $d$  are constants as well as  $a$  and  $b$ ). The formula  $\log. S = a + bt + \dots$  often gives a better representation with a smaller number of coefficients.

*Supersaturated solutions.* When a salt whose solubility increases with temperature is dissolved at a high temperature in water (or other solvent), and the solution is cooled, a temperature is reached whereat the solution is saturated with reference to a definite hydrate of the solid salt; but if the solution is further cooled salt does not separate, provided there is no crystal of the hydrate in question in contact with the solution. Such a solution is said to be supersaturated. A solution may be supersaturated with reference to one hydrate, but not supersaturated with reference to another hydrate. For example,  $\text{Na}_2\text{SO}_4 \cdot 7\text{H}_2\text{O}$  is more soluble in water than  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$ , and so a solution may be obtained, by dissolving  $\text{Na}_2\text{SO}_4$ , that is supersaturated as regards the decahydrate but not as regards the heptahydrate; that is to say, if a crystal of  $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$  is brought into the solution, at a certain temperature, the decahydrate crystallises out, but at the same time the solution is able to dissolve the hydrate with  $7\text{H}_2\text{O}$ . If temperature falls again the solution, of course, becomes supersaturated with reference to both the hydrates.

At one time the supposition was often held that the dissolved substances were present in supersaturated solutions in a state different from that in which they existed in ordinary solutions. More accurate investigations of the physical properties on both sides of the point of saturation have shown that there is no essential difference between the solution before and after saturation, but that the relation of a supersaturated to a saturated solution is exactly the same as that of a saturated solution to the solution before saturation.

*Colloidal solutions.* Certain substances, such as gelatin, absorb unlimited quantities of water and become swollen thereby; when much water has been taken up, liquids are formed which do not part with the dissolved body on cooling, as ordinary solutions do, but set to jelly-like substances. All compounds that form colloidal solutions have very large molecular weights; such compounds are acids of Mo, Si, Sn, Ti, and W; oxides of Sb, Fe, and Mn; sulphides of Sb, As, Bi, Cd, Co, Au, Fe, Pb, Hg, Ni, Pd, Pt, Ag, Ti, and W; many organic substances, such as caramel, dextrin, egg-albumen, tannin, &c.; and also some elements, such as Se and Ag. Some of these solutions are characterised by the fact that the addition of small quantities of foreign substances—as salts, acids, and bases—causes coagulation, whereupon the bodies in the colloidal solutions become insoluble. For that reason it is generally supposed that colloidal solutions are intermediate between emulsions and true solutions. Emulsions—*e.g.* a fine deposit of alumina—possess the special property that the emulsionised bodies are thrown down much more quickly in presence of electrolytes, and also of other foreign substances, than in absence of these (Barus & Schneider, *Z. P. C.* 8, 291 [1891].) Colloidal substances having

molecular weights under 50,000—gelatin or gum, for instance—are characterised by the fact that if their solutions are solidified by cooling they again become liquid and transparent when heated. Colloids having molecular weights greater than 50,000 do not share in this property, but behave, in this respect, like very supersaturated solutions (Sabanejeff, *J. R.* 1891. [1] 80; *Z. P. C.* 9, 89 [1892]). When colloids take up water, and swell but do not dissolve, heat is produced; when they dissolve heat disappears (Wiedemann & Lüdeking, *W.* 25, 145 [1885]).

*Reasons for assuming the existence of hydrates in solutions.* When a dissolved substance is isolated, by various methods, from its solvent the solid generally separates in combination with water of crystallisation. It has, therefore, been generally supposed that a preponderating quantity of this hydrate must be present in the solution. This conclusion is not, however, tenable; for if only a minimum quantity of the compound that separates out were present in the solution this might suffice to cause the separation. The following consideration has been brought forward as an argument in favour of the existence of hydrates in solutions. A solution of 57 parts by weight HI and 43 parts water boils at 127°, and the distillate has the same composition as the residue; this lends some countenance to the view that this mixture behaves like a definite chemical compound. On adding water to this solution and distilling a more dilute acid at first passes over, and at last the acid with 57 p.c. HI distils off. If the solution contains more than 57 p.c. HI to begin with, the distillate at first contains a more conc. acid, and, later, acid of 57 p.c. This behaviour is simply explained in the following way. A solution of 57 p.c. HI possesses a minimum vapour-pressure, so that both less dilute and more dilute solutions at the same temperature have larger vapour-pressures. Speaking generally, the vapour from a solution does not contain both components in the same proportion as the solution itself. In the case under consideration the vapours from the more dilute solutions contain more water (in proportion to HI) than the solutions, and the vapours from the less dilute solutions contain, relatively, more HI. The dilute solutions increase in concentration as distillation proceeds, the boiling-point rises, and there is at last produced the 57 p.c. solution which possesses the lowest vapour-pressure at an equal temperature—i.e. the highest b.p. (127°) at an equal pressure. If, on the other hand, distillation is commenced with a more concentrated solution proportionally more HI passes over, and an approach is gradually made, from the other side, to the solution with highest b.p. There is, therefore, no binding reason for regarding this solution as a definite chemical compound. For, indeed, the composition of the solution changes according to the pressure under which the distillation is conducted; and this could not well be the case were the solution really a definite chemical compound.

In investigating the freezing-points and vapour-pressures of solutions it was found that in many cases the deviation from the freezing-point and vapour-pressure of the pure solvent

was proportional to the quantity of substance (salt) in solution. But in other cases this proportionality seemed not to be maintained unless the supposition were made that a portion of the water had combined with the dissolved substance (Wüllner, *P.* 103, 529; 105, 85; 110, 564 [1858, 1860]; de Coppet, *A. Ch.* [4] 23, 366; 25, 502; 26, 98 [1871-2]; Rüdorff, *P.* 114, 63; 116, 59 [1861-2]; 145, 599 [1870]). It was, therefore, supposed that such compounds as HI, HCl, BaCl<sub>2</sub>, CaCl<sub>2</sub>, NaBr, &c., were combined in aqueous solutions with definite quantities of water of crystallisation. But the recently-discovered laws which express these phenomena lead to very different methods of explanation, so that the conclusion that these compounds exist as hydrates in solutions seems, in this respect, to be entirely without foundation.

Mendeléeff not long ago examined the changes in the S.G., accompanying changes in the composition, of aqueous solutions of alcohol and of sulphuric acid (*Z. P. C.* 1, 273 [1887]); he thought he had found abrupt irregularities in the changes of S.G. He supposed, without any theoretical foundation, that at the concentrations whereat these occurred the solutions corresponded to perfectly definite hydrates. Pickering (*Z. P. C.* 6, 10 [1890]) showed, as the result of more accurate investigations, that Mendeléeff's conclusions rested on inaccurate observations. Pickering, however, accepted Mendeléeff's idea, and supposed that the higher derivatives of the S.G. in reference to percentage composition showed similar irregularities. He treated the freezing-points and the electrical conductivities of solutions in the same way, and he supposed that in all these cases he had discovered such irregularities as indicated the existence of definite hydrates. It is absolutely impossible to reconcile the numbers for the electrical conductivities of dilute solutions of acids and bases (e.g. for acetic acid) with Pickering's views; nor do the most recent investigations on the freezing-points of very dilute saline solutions (Jones, *Z. P. C.* 11, 534; 12, 623 [1893]) in any way agree with these views. Moreover, the method used by Pickering is not free from objection under any conditions.

From an extended and systematic investigation recently made into the constitution of ammoniacal metallic compounds, and compounds analogous therewith, Werner (*Zeit. f. anorg. Chem.* 3, 267 [1893]) concluded that in electrolytically conducting salt solutions the metallic atoms of the salts might be expected to be generally accompanied by six molecules of water, and that those salts which readily combine with water of crystallisation would be the best conductors. This statement is not, however, in any way in keeping with the experimental results. The salts of ammonium, K, Rb, and Cs conduct better than any others that have been examined; after these come the salts of Na, Li, and the metals of the earths; and then, much behind these, come the salts of the heavy metals; but water of crystallisation combines most readily with the salts last mentioned, and least readily with those mentioned first.

Conclusions regarding the existence of hydrates of substances in solution have also been drawn from the results of investigations of other

u properties, such as contraction or, or production of heat, during solution, salty, &c.

In general, it has been supposed that where properties exhibited a maximum or minimum other purely mathematical character—there existed a definite hydrate of corresponding composition. Attention may, however, be called to the fact that these points generally shift with changes of temperature, so that the hypothetical hydrate must have a different, and constantly changing, composition at different temperatures—a conclusion which is not in keeping with the representation of the hydrate as a definite chemical compound.

It is, indeed, in the highest degree likely that when definite hydrates separate from a solution the same hydrates were previously present in the solution, perhaps only in small quantity; but we have as yet no accurate knowledge as to the magnitude of the quantity. The methods that have been used in investigating this most interesting question have scarcely brought to light a single new result, although many and renowned investigators have carried out a very large amount of work in this direction.

The solubility of a salt, at constant temperature, is to a small extent dependent on pressure. Sorby was the first to carry out detailed investigations on this subject (*Pr.* 12, 538 [1863]). The following statement may be demonstrated by the use of the dynamical theory of heat. When the total volume of salt and solution is diminished (or increased) by the taking up of salt into the solution, then the solubility increases (or diminishes) with increased pressure. The researches of Braun (*W.* 30, 272 [1887]) have confirmed the theoretical conclusions.

**Dilute solutions. Osmotic pressure.**—If a quantity of the pure solvent is floated on a solution, a movement of the dissolved substance takes place and the substance strives to distribute itself throughout the whole of the solvent. This occurrence is completely analogous with another; if a cylinder is filled with  $\text{CO}_2$  and the mouth is covered with a membrane, another cylinder is filled with  $\text{H}$  and placed mouth-downwards on the first, and the membrane is withdrawn, the two gases begin to diffuse into each other (notwithstanding the action of gravitation). The  $\text{H}$  is driven downwards by its partial pressure, and the  $\text{CO}_2$  is driven upwards. The velocity of diffusion is proportional to this propelling force, otherwise it is dependent only on the freedom of motion of the molecules among each other. The inverse value of this freedom of motion is called *molecular friction*. The following statement expresses the results of experiment: the velocity of diffusion is proportional to the difference between the partial pressure of one of the two gases in the upper and lower parts, and is inversely proportional to the friction of the molecules. Solutions behave in a similar way. The substance in solution in the under layer strives to distribute itself into the upper layer; this striving corresponds to the pressure of a gas, and, as will be shown immediately, it is equal to the so-called osmotic pressure. The solvent is driven downwards by the same force. In this case also the velocity of diffusion is proportional to the osmotic pressure, and is inversely

proportional to the friction of the molecules of the dissolved substance against the solvent. The only difference between this case and that of gases is that molecular friction is very much larger in liquids, a fact that is explained by the great number of molecules against which a molecule of the dissolved substance collides during its movements.

The amount of molecular friction is known in certain cases, viz. for electrolytes. Let a cubical trough (sides 1 cm.) be filled with the solution of an electrolyte (e.g.  $\text{NaCl}$ ), and let an electric current be passed through the trough by the help of two electrodes A and B. The positive electricity is carried by the metallic parts (Na) of the electrolyte in the direction of the current (towards B); the negative electricity travels with the negative radicle (Cl) of the electrolyte towards A. If the Na and Cl atoms—or ions, as they are called in this case—are impelled by unit electrical force, the Na ions will move with a velocity  $v_1$ , and the Cl ions with the velocity  $v_2$ . These velocities can be determined, partly indirectly from the conductivity and the migration numbers of Hittorff, partly directly by chemical analysis. Putting the corresponding frictions as  $r_1$  and  $r_2$ , then  $v_1 = \frac{1}{r_1}$  and  $v_2 = \frac{1}{r_2}$ . The frictions of a large number of ions have been determined in this way. If we now have a layer of pure water floated on a solution of  $\text{NaCl}$ , in a vessel, then the velocity of diffusion,  $D$ , is equal to the quotient of osmotic pressure,  $O$ , and the frictions  $r_1 + r_2$  of the salt. We have, therefore,  $D = \frac{O}{r_1 + r_2}$ . Nernst (*Z. P. C.* 2, 613 [1888])

has completely established the accuracy of this formula.

Osmotic pressure can be measured directly. Let us suppose that in the foregoing example we had a division separating the solution of  $\text{NaCl}$  from the water, and that the division allowed water, but not  $\text{NaCl}$ , to pass through it (a so-called semipermeable membrane); *v.* fig. 3. Such a membrane is obtained by impreg-

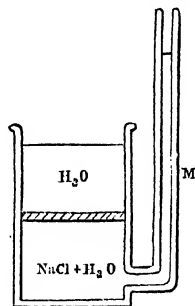

FIG. 3.

nating a plate of porous burnt clay with  $\text{ppd Cu}_2\text{Fe(CN)}_6$ . The water will then be driven downwards, and will be compressed in the lower part of the apparatus; the pressure in this division will increase; this may be confirmed by using a manometer (M, fig. 3). Equilibrium is attained after a time, and the manometer then indicates a certain pressure, which is called the

osmotic pressure of the solution. When no more water is driven downwards, then, in the case in point, the partial pressures of the water in the upper and lower parts of the apparatus are equal. The excess of pressure in the lower part—that is, the osmotic pressure—is then equal to the partial pressure of the NaCl molecules. Measurements of this kind have been made by Pfeffer, Tammann, and Adie (*Osmotische Untersuchungen*, Leipzig, 1877; *W.* 34, 229 [1888]; *C. J.* 59, 344 [1891]).

Semipermeable membranes are found in the lining of living cells which incloses the contents of the cell. De Vries made observations with cells of *Tradescantia discolor* and *Begonia manicata*; Donders and Hamburger used blood-cells. If a cell is immersed in water the cell swells, because of the entrance of water; if a soluble substance is added to the water, in constantly increasing quantity, the water will at last be driven equally inwards and outwards; if this limit is overpassed, the water passes out of the cell and the protoplasmic contents of the cell shrink together. The whole process may be followed by the help of the microscope. The limit reached immediately before shrinkage begins is characterised by the attainment of equality between the osmotic pressure of the cell-contents and that of the surrounding solution. By bringing similar cells into solutions of different substances it is possible, in this way, to determine the concentration that must be attained by two solutions in order that they may possess equal osmotic pressures. Using the results of Pfeffer and de Vries, van't Hoff made an examination of the magnitude of osmotic pressures. He found that the osmotic pressures exerted in their solutions by non-conductors of electricity—such as cane sugar, urea, glycerin, &c.—were exactly the same as the pressures which these substances would exert, in accordance with Avogadro's law, were they present as gases in the same volume as the volume occupied by the solutions. The osmotic pressure is therefore proportional to the concentration and the absolute temperature (law of Boyle and Gay-Lussac); this was confirmed by Pfeffer's investigations (van't Hoff, *Handingar der Stockh. Ak.* 21 [1886]; *Ar. N.* 20 [1886]; *Z. P. C.* 1, 481 [1887]).

An explanation of gaseous pressure is found in representing it as the result of the bombardment of the walls of the vessel by the gaseous molecules. Similarly, osmotic pressure is thought of as resulting from the knocking of the molecules of the dissolved substance against the walls of the containing vessel. The gaseous laws hold good in all respects for osmotic pressure.

*Vapour-pressure of solutions.* Let there be a solution, say of cane sugar, in a trough, separated by a vertical semipermeable membrane from pure water, and let the membrane extend above the solution; the air above the liquid behaves exactly like the semipermeable membrane, inasmuch as it allows the water to pass through (as water-vapour), but it does not allow the cane sugar to pass through (because of the non-volatility of the sugar). The water has, therefore, a tendency to pass across through the air as well as through the semipermeable membrane from the water in the solution. This cir-

cumstance may be expressed by saying that the pressure of the water-vapour is greater over the water than over the solution. In like manner it follows that solutions which have equal osmotic pressures have also equal vapour-pressure. By making use of the second law of thermodynamics it can be shown (van't Hoff, *l.c.*) that a solution containing  $n$  molecules of dissolved substance to  $N$  molecules of solvent has a vapour-pressure,  $P$ , which is given by the formula

$$P = \left(1 - \frac{n}{N}\right)p,$$

where  $p$  = the vapour-pressure of the pure solvent. (The molecular weight of the solvent must be taken as that of the substance in the gaseous state at the same temperature.) This formula was originally experimentally established by Raoult; it agrees well with experience (*C. R.* 103, 1125 [1886]).

*Boiling-points of solutions.* According as the vapour-pressure of a solution is less than that of the solvent (assuming that the dissolved substance possesses no marked vapour-pressure), so the solution begins to boil, under a definite external pressure, at a higher temperature than the pure solvent. The following formula may be deduced from the dynamical theory of heat:

$$E = \frac{0.2 \tau^2}{L} \cdot n,$$

where  $E$  is the increase in the boiling-point of the solvent brought about by dissolving  $n$  molecules of the substance in 100 grms. thereof,  $\tau$  is the absolute boiling temperature, and  $L$  is the latent heat of vapourisation of 1 grm. of the solvent. Beckmann has contrived an apparatus for determining  $E$ , and therefore for finding  $n$ —that is, for determining the molecular weight of the dissolved substance when the quantity thereof in 100 grms. of solvent is known. He has shown that the formula gives results which agree closely with experience (*Z. P. C.* 5, 76 [1890]).

*Freezing points of solutions.* When a solution is caused to freeze, in most cases only the pure solvent separates as a solid. The solid substance is in equilibrium with the solution at the freezing-point; hence, the vapour-pressure of the solvent over the solid and over the solution must be equal, as otherwise distillation would take place from the one to the other, and equilibrium would not be attained. For the sake of simplicity let us take water as the solvent. Ice and water have, therefore, the same vapour pressure at the freezing-point of the latter ( $0^\circ$ ); but an aqueous solution has a smaller vapour pressure at  $0^\circ$ ; hence at  $0^\circ$  ice cannot have the same vapour pressure as an aqueous solution, but this equality occurs only at a lower temperature. In other words, the freezing-point of a solution is lower than that of the solvent. Van't Hoff (*l.c.*) has deduced the following expression from the dynamical theory of heat,  $E = \frac{0.2 \tau^2}{W} \cdot n$ , where  $E$  is the difference

between the freezing-points of the pure solvent and a solution therein, which solution contains  $n$  gram-molecules of the dissolved substance in 100 grms. of the solvent,  $\tau$  is the absolute temperature, and  $W$  is the latent heat of fusion of 1 grm. of the solvent. This formula is of much importance, for the molecular weights of very

many substances have been determined by its help. It is immaterial in this case whether the dissolved substance exerts a considerable vapour-pressure or not, for only the pure solvent freezes out. The following table gives some values calculated by the formula placed side by side with the values obtained by experiment, for the case where  $n = 1$ :

	E observed	E calculated
Water. . .	18.9	18.9
Acetic acid . .	38.6	38.8
Formic acid . .	27.7	28.4
Benzene . . .	50.0	53.0
Nitrobenzene . .	70.7	69.5

**Electrolytic dissociation.** When determinations of molecular weights are made, by the foregoing methods, based on osmotic pressures (de Vries), freezing-points (van't Hoff, Raoult), depressions of vapour-pressures (Raoult), or increments of boiling-points (Beckmann), the values obtained for all those substances whose solutions conduct electricity are much smaller than would be expected. For instance, the results obtained by working with a half-normal solution of NaCl lead to the value 31.6 for the molecular weight of the salt, a number which is 1.85 times smaller than the calculated value, 58.5 (NaCl). From this and many other considerations Arrhenius drew the conclusion that the molecules of electrolytes are largely dissociated in aqueous solutions; about 85 p.c. of the NaCl, for instance, in an aqueous solution of this salt is regarded as dissociated into Na and Cl. This conclusion is completely analogous with those which are drawn regarding the dissociation of the molecules of ammonium salts and other substances, in the gaseous state, from observations of the abnormal vapour densities of these substances. The development of the theory of electrolytic dissociation, based on these considerations, and confirmed in the fullest way by experience, has lent much support to the theory of solutions which has already been sketched. This part of the subject is treated by Ostwald in the article *ELECTRICAL METHODS*, to which reference should be made (this vol., pp. 187-221).

Some of the deductions regarding diffusion, solubility, and affinity must, however, be mentioned here.

**Diffusion of mixtures.** When a solution of HCl is placed in contact with pure water, the HCl gradually diffuses into the water. Inasmuch as most (almost all) of the HCl molecules are dissociated, one would expect the diffusion to result in a separation of the H and Cl from each other, just as the alums and the double salts of the sulphates of the alkalis and the magnesium metals, which are partially decomposed in aqueous solution, can be separated into their constituent salts in this way (Graham, *T.* 1850. 1, 805; Marignac, *A. Ch.* [5] 2, 546 [1874]). But this separation does not occur. The H moves into the water more quickly than the Cl, and, because of the positive electrical charge of the H ions, the water becomes positively and the solution negatively charged. If this charging is not carried off by metallically connected unipolarisable electrodes placed in the solution and in the water (v. this vol. p. 212), it prevents the separate diffusion of the H and the Cl. But there is another way whereby the restrain-

ing force of the electrical charge on the diffusion of the H may be diminished—namely, by addition of chlorides. For instance, the velocity of diffusion of HCl (properly speaking, of H) is increased in the ratio of 1:2.24 by adding 25 times the quantity of  $\text{NH}_4\text{Cl}$  (Arrhenius, *Z. P. C.* 10, 51 [1892]). Similar, although not so strongly marked, characteristic phenomena, which find an explanation in the dissociation theory, have been observed by Graham and Marignac.

**Decrease of solubility by addition of foreign salts.** Nernst (*Z. P. C.* 4, 372 [1889]) was the first to draw attention to the conclusion from the theory that a slightly soluble salt, e.g. silver acetate, must be more soluble in pure water than in a solution that contains other silver ions (e.g.  $\text{AgNO}_3$ ) or acetate ions (e.g.  $\text{NaC}_2\text{H}_3\text{O}_2$ ). Similar relations are shown by gases which partially decompose (e.g.  $\text{NH}_4\text{SH}$ ); these exhibit smaller vapour-pressures when one of the two components ( $\text{NH}_3$  or  $\text{H}_2\text{S}$ ) is added. This lowering of solubility can be calculated from the laws of mass-action, with results which agree well with experience (Noyes, *Z. P. C.* 9, 603 [1892]).

**Division of a dissolved substance between two solvents.** Berthelot and Jungfleisch examined the distribution of succinic acid between ether and water, and found that the concentrations of the acid in the aqueous and in the ethereal solution were in a constant proportion, which appeared to be independent of the absolute concentration. Many other substances were found to behave in the same way (*A. Ch.* [4] 26, 396, 408 [1872]). This result corresponds completely with Henry's law for gases. It is readily deduced from the theory; but in doing this it is assumed that the dissolved substance has the same molecular weight in both solutions. If this is not the case—as, for example, in the distribution of benzoic acid between benzene and water—altogether different laws express the phenomena (these laws, also, are in keeping with experimental results; Nernst, *Z. P. C.* 8, 110 [1891]).

**Reaction velocities.** There are many so-called catalytic processes that are brought about by the H ions of acids—for instance, the inversion of cane-sugar, saponification of esters, &c. According to the theory, the velocity with which these reactions take place must depend only on the number of H ions that are present, and not on the nature of the reacting acid. This conclusion is confirmed by experience (Arrhenius, *Z. P. C.* 4, 226 [1889]; cf. *AFFINITY*, vol. i., especially pp. 77-81).

**Division of a base between two acids present in equivalent quantities.** Thomsen made investigations regarding the quantity of a base (NaOH) that reacts to form salts with two acids (e.g. HCl and HF) added in equivalent quantities. He found that, in the case quoted, 95 p.c. NaCl and only 5 p.c. NaF were formed in dilute aqueous solution. It may be deduced from the theory that the quantities of NaOH combining with the two acids (HCl and HF) are in the same ratio as the extents of dissociation of the acids at the same dilution. The observations of Thomsen and of Ostwald agree extremely well with this deduction from the theory (Arrhenius, *Z. P. C.* 5, 14 [1890]; cf. *AFFINITY*, vol. i. p. 81).

*Influence of temperature on rate of solution.*

If a finely and equally powdered substance is shaken with a solvent at two different temperatures, for a very short time, the rapidity of solution is found to increase rapidly with the temperature. For instance, the rates of solubility in water of cream of tartar and benzoic acid increase between 0° and 17° in the ratios 1:3.8 and 1:3.1.

*So-called solid solutions.* Palladium is able to take up much H, but the mixture retains the solid form. There is, therefore, here no proper solution; nevertheless, van't Hoff has shown that the laws which hold good for solutions are valid for this phenomenon also (*Z. P. C.* 5, 322 [1890]). There is formed at first an alloy, Pd<sub>2</sub>H, which possesses a definite dissociation pressure. If the pressure of the H is increased more H is absorbed, and the quantity absorbed is in direct proportion to the excess of pressure of the H. Henry's law, therefore, holds good. On this ground van't Hoff called mixtures similar to this 'solid solutions.' Solid solutions of thiophene and benzene have been examined by van Bijlert (*Z. P. C.* 8, 343 [1891]).

*Heats of solution.* A considerable quantity of heat is generally produced during the solution of a substance in a solvent. The heat of solution of a substance is defined to be the quantity of heat that appears during the solution of a gram-molecule of the body in much water. The following table gives the heats of solution of some of the commoner substances. Most of the numbers are taken from Thomsen (*Th.* 3, 195).

*Gases.*

Chlorine Cl <sub>2</sub> . . . . .	4870
Carbon dioxide CO <sub>2</sub> . . . . .	5882
Ammonia NH <sub>3</sub> . . . . .	8430
Hydrogen fluoride HF . . . . .	11800
" chloride HCl . . . . .	17310
" bromide HBr . . . . .	19940
" iodide HI . . . . .	19210
" sulphide H <sub>2</sub> S . . . . .	4560
Sulphur dioxide SO <sub>2</sub> . . . . .	7700

*Liquids.*

*Volume changes accompanying solution.*

In most cases the solution of a substance in water is accompanied by a considerable amount of contraction. For instance, a mixture of 100 c.c. alcohol with 100 c.c. water measures only 192.8 c.c. at 18°. The contraction may be so great that the volume of the solution is less than the volume of the water used as solvent: for instance, when Na<sub>2</sub>CO<sub>3</sub>, NaOH, or LiOH is dissolved in much water. The following table shows the volume change, in c.c., that takes place when one gram-equivalent of some of the most important compounds is dissolved in much water—e.g. in 10 litres:—

	H	Na	K	NH <sub>4</sub>
OH . . . . .	18	-5.8	8.6	—
Cl . . . . .	18.3	16.6	26.9	37.4
NO <sub>3</sub> . . . . .	29.0	28.0	38.5	48.2
$\frac{1}{2}$ SO <sub>4</sub> . . . . .	16.2	6.4	15.7	24.2

A mixture of 40 grms. NaOH with 10 litres water occupies, therefore, a volume of 9994.2 c.c. only.

When the solvent is other than water an increase of volume sometimes takes place; for instance, a mixture of 100 c.c. alcohol with 100 c.c. CS<sub>2</sub> occupies about 202 c.c.

*Specific heats of solutions.* The water value of a solution of a salt in water is not equal to, but is generally less than, the sum of the water values of the water and the salt. In a few cases this decrease is so great that the water value of the solution becomes less than that of the water used as solvent. The following data show the water values of one gram-equivalent of the chief salts in extremely dilute solutions (according to the determinations of Thomsen):—

	H	Na	K	NH <sub>4</sub>
OH . . . . .	18	-27	-33	—
Cl . . . . .	-28	-16.3	-30	-13
NO <sub>3</sub> . . . . .	-10.7	-8.7	-16	7
$\frac{1}{2}$ SO <sub>4</sub> . . . . .	9	-25	-36	-16

The water value of a solution of 40 grms. NaOH in 10 litres water, for instance, is not only not greater than that of the water alone (10,000), but is distinctly smaller (9,973).

*Deviations shown by concentrated solutions.*

The laws that have been stated for the osmotic pressure, the lowering of freezing-point, the raising of boiling-point, and the lowering of vapour-pressure, brought about by substances in solution, are valid, strictly speaking, only for very dilute solutions. Deviations from these laws occur when the solutions are more concentrated. Sometimes the observed values are smaller than those theoretically deduced. In such cases it is supposed that molecular aggregates are formed. This occurs, for instance, with solutions in benzene of oxims, alcohols, phenols, and fatty acids, and also with fairly concentrated aqueous solutions of the sulphates of Mg, Cu, Zn, and Cd, and CdI<sub>2</sub> (Beckmann, *Z. P. C.* 2, 737 [1888]; Arrhenius, *Z. P. C.* 2, 496 [1888]). On the other hand, most concentrated aqueous solutions give values greater than the calculated values; this is made especially evident by Tammann's investigations into the vapour-pressures of salt solutions at 100° (*Mém. de l'Acad. de St. Pétersbourg* [7] 1, 85 [No. 9, 1887]). An explanation of this behaviour has been sought for in the attraction between the

solvent and the dissolved substance (Arrhenius, Z. P. C. 10, 40 [1892]).

S. A.

**SOLUTIONS II.** The view that hydrates exist in aqueous solutions, and analogous compounds in non-aqueous solutions, is one which has long been held by many chemists; it is only in the last few years, however, that the hydrate or association theory has assumed a precise form, and that definite experimental evidence in support of it has been accumulated. In giving some account of the present position of this theory it will be convenient to collect the evidence on which it depends under the headings 'general' and 'special,' and to discuss separately the bearing which recent work on dilute solutions has upon it. Aqueous solutions have naturally been more studied than solutions in other solvents, but these other solutions have been investigated sufficiently to show that they are similar to aqueous solutions in every respect, except as regards electric conductivity. Although, therefore, to simplify matters in the present article, in most instances aqueous solutions alone are mentioned, it must not be understood that the arguments do not apply equally to other cases.

**General.** The changes accompanying dissolution seem to be in every respect similar to the recognised accompaniments of chemical combination: evolution of heat, a more or less profound alteration in the nature of the reagents, and an irregular variation in the properties of the resulting solution with regular variations in the proportions of dissolved substance and solvent. For reasons which will be mentioned below, these irregularities may often not be very pronounced, but it may safely be stated that every attempt which has been made to express the properties of any series of solutions by a simple expression agreeing, within the limits of experimental error, with the observed values throughout a wide range of concentration has been unsuccessful.

The affinity which a large number of substances possess for water, as evidenced by the many solid compounds which they form with it, and by the heat evolved in their formation, renders it *prima facie* extremely improbable that these substances should exist in presence of excess of water without combining with it. It is, moreover, those very substances which exhibit the greatest tendency to form solid hydrates which are generally most soluble. A more careful study of the thermal phenomena of solutions places this argument beyond the range of mere speculation. From the known heat of fusion of water and of a few anhydrous salts we can obtain a very close estimate of what the heat of fusion of any hydrated salt would be, if no change beyond the mere passage from the solid to the liquid condition occurred; with hexahydrated calcium chloride, for instance, the heat of fusion under such circumstances would be 11,000 to 12,000 cal., and on the most exaggerated estimate could not exceed 14,000 cal., whereas if decomposition as well as mere liquefaction occurred the heat absorbed would be at least 25,000 cal., since the heat of fusion of the  $6\text{H}_2\text{O}$  alone is 9,500 cal., and the heat of combination of  $\text{CaCl}_2$  with  $6\text{H}_2\text{O}$  (both solid) is 14,500 cal. The observed heat of fusion, however, is only 11,417 cal., a value which disproves that any consider-

able change beyond mere liquefaction has occurred during the fusion—i.e. the combination which existed in the solid must exist also in the liquid. The data in the case of sulphuric acid afford more striking evidence of a similar character. The heat of combination of solid water with the solid acid to form the solid monohydrate is 6,550 cal., and if, when the reagents are mixed in the liquid condition, they do not combine chemically, far less than this amount of heat would be evolved; whereas the heat actually evolved is found to be almost identical with the above, namely 6,667 cal.

The separation of a crystalline hydrate from a solution is an argument to which due weight has hardly yet been attributed in favour of the existence of that hydrate in the solution, although not necessarily in large quantity. If there are no molecules of the hydrate existing as such in the liquid, these must have been deposited in the solid form at the moment of their formation, whereas we know that whenever deposition occurs simultaneously with formation, as in the precipitation of an insoluble salt, the substance is deposited in the amorphous and not in the crystalline condition.

If, as would appear to be the case, it is necessary to admit the existence of hydrates in concentrated solutions, it is necessary to admit their existence in dilute solutions also. The mass action of an excess of one or other of the constituents of any composite fluid is well known, and is universally accepted: it must operate with hydrates as much as with other substances, and must do one of three things: either (1) it must increase the stability or amount of the particular hydrate present, or (2) it must combine with it to form a higher hydrate (if it is the water of which excess is added), or (3) it may decompose the hydrate by reacting with the non-aqueous constituent of it to form new compounds, as when free alkali and acid are produced (a decomposition, however, which can be proved in many cases to occur to but a negligible extent), but in no case could excess of water decompose the hydrate taken so as to liberate the dissolved substance in the anhydrous condition. The thermal phenomena of solution afford important evidence in this case also; to interpret them properly, however, it must be remembered that the dissolution of a substance in excess of solvent entails the separation of the particles of that substance from each other to the same extent as if it were vapourised, and that to effect this separation the same amount of heat must be absorbed in either case. The heat evolved due to the reaction of a liquid with excess of solvent is, therefore, the observed heat of dissolution *minus* the heat absorbed in vapourisation, and, in the case of a solid, the heat of fusion as well as that of vapourisation will have to be subtracted. Making allowance for these so-called physical changes, we find that the formation of every concentrated solution—that is, a solution which contains hydrates—is accompanied by the evolution of heat, and inasmuch as, with the same allowance, dilution is always accompanied by a further evolution of heat, the action of the diluent cannot be regarded as a reversal of the initial reaction, but rather as an extension and completion of it, the hydrates present in the con-

concentrated solutions being increased in amount or in complexity thereby. When matters are simplified by dissolving a gas, instead of a liquid or solid, and adjusting the pressure of the gas or the quantity of solvent so that the former occupies the same volume after as before dissolution, we still find that a very considerable evolution of heat occurs; with the haloid acids this is as much as 17,000 cal., and though this may be glossed over by some of the advocates of the physical theory by stating that the decomposition of the acids into their ions, which they consider occurs, evolves a very large amount of heat, no such explanation can be offered in cases where no such decomposition is imagined, and it has been proved that the dissolution of gaseous non-electrolytes both in water and in other solvents is accompanied by the evolution of as much as 5,000 to 14,000 cal. In the face of such a considerable loss of potential energy, it is impossible to maintain that the substances losing it remain unchanged, and that the dissolved substance can, in any true sense, be still gaseous and uncombined with the solvent. It is important to note that van der Waals, through a different line of reasoning, has arrived at the same conclusion as to the necessity of recognising some action evolving heat between the substance and solvent, even when the former is in the so-called dissociated condition.

Amongst the general considerations favouring the view that dissolution consists in the formation of liquid compounds, not the least important is that this gives us some intelligible reason for dissolution occurring at all, whereas if the solvent is regarded as being inert and only playing the part of so much empty space (as some of the advocates of the physical theory have maintained), we have no explanation of why dissolutions occur; the presentation of empty space to a stable solid does not make the latter fill the empty space, and even attributing dissolution to the possession of a certain 'solution pressure' by the dissolving substance would appear to amount to no more than stating that a substance dissolves because it does so.

*Special.* Berthelot determined the heats of dissolution of various series of solutions of different concentrations, and concluded that his results when plotted out showed the presence of changes of curvature or inflections at certain points, indicative of the existence of hydrates in the solutions. In many cases he adduced various special considerations in support of the existence of the hydrates thus indicated, but his determinations were not sufficiently numerous or accurate, nor were his methods of examining them sufficiently precise, to lead to more than vague conclusions. Thomsen's investigations on the same subject were equally unsatisfactory; he sought to disprove the existence of any such changes of curvature by finding empirical equations to represent each series of results, but in the four cases which he thus investigated the equations deduced express but a small portion of the whole series, leaving in the remainder errors ten and a hundred times greater than the experimental error. Mendeleeff next took up the question from a different point of view. Theoretical considerations led him to conclude that solutions consisted of different hydrates according to the

amount of water present, and that, if not more than two hydrates were ever present together in the same solution, there would be definite changes of curvature in the figures representing the properties of the solutions at the concentrations corresponding to these hydrates; that is, that the rate of change in the property with change of concentration would be different when the solutions consisted of the hydrates A and B from what it would be when they consisted of B and C, so that there would be a change at a concentration corresponding to the composition of B, and further, he concluded that these rates of change (first differential co-efficients) in the case of the densities would be rectilinear functions of the percentage composition between the points A and B, B and C, &c. (It should be noticed in passing that the idea which lies at the root of Mendeleeff's conception—and, to a certain extent, of Berthelot's also—is that the water in any solution is nearly entirely combined with the dissolved substance, and not merely that the solution consists of a simple hydrate mixed with excess of free water.) That the concentration-rate of change of the densities is representable, within experimental error by a series of straight lines is probably true in many cases, but in the two cases on which Mendeleeff chiefly relied for proof these first differences are conspicuously curvilinear throughout. The reason of this, doubtless, is that solutions of a given concentration generally contain more than the two hydrates which he postulated. Roozeboom's work on ferric chloride, and Pickering's on sodium hydroxide, render it probable that five or six hydrates may co-exist in the same solution; at any rate, as many as four have actually been obtained from certain solutions. Pickering next attacked the subject from a purely experimental point of view. The distinctive feature of his work is the search for changes of curvature (breaks) by the application of a flexible lath to his plotted results. A lath bent by the application of two couples near its extremities forms, for all practical purposes, a curve of a very simple nature; and it has been proved that the use of such a lath is tantamount to, and leads to precisely the same conclusions as, the application of ordinary parabolas with three or four constants deduced mathematically from the experimental values; and in several respects, besides expeditiousness of application, this method is superior to the mathematical method. The mere fact that a certain figure may be represented accurately by a series of parabolas is by itself no proof that it really consists of these independent curves, any more than the existence of breaks can be disproved by finding an artificial equation which will bridge them over; the correctness of any particular form of representation can be measured only by the results to which it leads, and in this respect the discontinuous expressions would appear to be highly satisfactory. The positions of the breaks are not dependent on the taste of the draughtsman: the figures examined seem to split up naturally into certain sections only, and when drawn in these sections it was found, in some dozens of series of experiments, that the apparent error of the points agreed within 5 or 10 per cent. with the known experimental error (though in a great number of the cases the true

magnitude of the latter was not as after the drawings were made), whereas drawings of a similar character, but placing the breaks at other points, or drawings obliterating the breaks altogether, represented the error of the points to be far larger, often 10 or 100 times larger, than the known experimental error. It must be remarked that, once the magnitude of the experimental error is known with certainty, no drawing can be accepted unless it agrees closely with it, and Pickering has devised a method by which the experimental error can be accurately determined independently of any considerations other than the examination of the final results themselves; he has also devised a means of obtaining a numerical estimate of the acceptability of any drawing, by combining together the various factors which are usually taken as affording a criterion of acceptability. Again, when sections of increasing lengths are taken, and these are represented by single parabolas, or bent-lath curves, there is little or no increase in the apparent error of the points till the sections extend beyond a point where one of the supposed breaks exists, but as soon as they do so there is a large and sudden increase, indicating that some real change at the point in question exists. Moreover, it has been shown that in a case where two parabolas will represent a series of results perfectly, a single parabola will not do so, even if it contain as many constants as the two parabolas together contain. The strongest argument, however, in favour of the reality of these breaks is that the various properties of any series of solutions, although they form figures differing from each other widely in general form, are yet all thoroughly concordant as to the positions at which the breaks occur. The properties of sulphuric acid which were investigated were the densities at four temperatures and the contraction on mixing deduced from them, the heat of dissolution, the thermal expansion, the electric conductivity (Kohlrausch's values), and the thermal capacity; subsequently also the freezing-points and van der Willigen's values for the refractive indices were investigated. Perkin also found indications of two of the breaks in his determinations of the magnetic rotations, and still more recently Féry has recognised some other of the breaks in his own measurements of refractive indices. Three different properties were also examined by Pickering in the case of calcium chloride and nitrate, and were found to show a similar concordance.

That the breaks are really due to, and indicate the presence of, compounds in solution is shown by the fact that, not only in the cases above mentioned, but also in many others where other solvents besides water were used, they always occur at points which correspond within small limits with definite molecular proportions—wherever, that is to say, the proportion of substance to solvent is sufficiently simple to permit of any conclusions at all being drawn in the matter. Further evidence on this point was also afforded from a study of the freezing-points of fourteen of the alkyl amines, where, with one exception, hydrates of the very compositions indicated by breaks in the case of some of the amines were isolated in the crystalline condition in the case of the others. Finally, as a more striking, though perhaps not more cogent, argument, we

have isolated, in the crystalline condition of no less than six new hydrates, the existence of which had been foreshadowed in the properties (chiefly densities) of the solutions—namely,  $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ ,  $\text{HBr} \cdot 3\text{H}_2\text{O}$ ,  $\text{HBr} \cdot 4\text{H}_2\text{O}$ ,  $\text{HCl} \cdot 3\text{H}_2\text{O}$ ,  $\text{HNO}_3 \cdot \text{H}_2\text{O}$ , and  $\text{HNO}_3 \cdot 3\text{H}_2\text{O}$ —the last three being especially conspicuous examples, for the only marked breaks which the densities showed coincided with the only hydrates which were subsequently isolated.

Two important features of the conclusions drawn from the above-mentioned work on sulphuric acid should be mentioned: firstly, the large number (18–20) of hydrates of which indications were obtained; secondly, the complex nature of hydrates in very dilute solutions. Any improbability which might be considered to attach to the former conclusion (though, in reality, no data exist on which to found any estimate of the probabilities in such a case) is removed by the fact that a still larger number of hydrates (when equal ranges of concentration are compared) have been isolated in the crystalline condition from solutions of sodium hydroxide. The complexity of the hydrates indicated extends up to compounds with hundreds and even thousands of molecules of the solvent, but with the explanation to be mentioned below as to their possible constitution, these hydrates can scarcely be branded as improbable; at any rate, the breaks which indicate their existence appear to be precisely similar in nature to those which indicate the presence of the simpler hydrates. Pickering has investigated the freezing-points of many dilute solutions besides those of sulphuric acid, and has found that nearly all of them show indications of similar changes, and those recognised in the cases of sodium chloride and sulphuric acid have received further confirmation from a series of results made by H. Jones; a confirmation of special importance, since Jones's determinations were made with the view of disproving the existence of breaks.<sup>1</sup> Complex hydrates, though of a comparatively small degree of complexity, would appear to exist in regions other than those of very dilute solutions; two such were indicated in the neighbourhood of the monohydrate of sulphuric acid, and a similar one, perhaps another also, has been isolated in the case of soda. These are probably compounds of two different hydrates.

It is important to note that the changes of curvature here described need not necessarily be absolutely abrupt. On the strength of experimental evidence only, where experimental error necessarily exists, it is obviously impossible to prove or disprove the abruptness of any change, and no satisfactory mathematical theory has yet been formulated to lead to any views on the subject. It is sufficient for the purpose that comparatively abrupt changes exist. Nor should it be expected that these changes would necessarily be of a very marked character, for a large proportion of the factors determining the properties of solutions must be of a purely physical or even mechanical character; the densities of sulphuric acid solutions, for instance, must rise more or less gradually from 1 to 1.85, and it is only in

<sup>1</sup> It should be noted that Jones himself asserts that his results entirely disprove Pickering's 'breaks' (*N. B.* 36, 647, 1633).—M. M. F. M.

the variations from the 'more' to the 'less' that we can expect to find evidence of intermediate compounds.

*Application of the hydrate theory to explain the properties of dilute solutions.* Diversity and irregularity are some of the most marked features of the properties of concentrated solutions, and though in dilute solutions these irregularities are much less conspicuous (as, indeed, we should expect them to be when the hydrates present become excessively complex and, consequently, excessively unstable), they are still recognisable, and it is only in the most extreme dilution, where the experimental error amounts to a large fraction of the total quantities measured, that the results can be expressed within the limits of this error as an apparently regular function of the concentration. It may safely be stated that any purely physical theory which confines itself to regions of extreme dilution, and which ignores some of the most marked features of dissolution, as well as the mass of direct evidence showing the existence of compounds in solution, cannot be accepted as a complete theory; nor, on the other hand, can the hydrate theory of solutions be accepted as satisfactory unless it can be shown to be consistent with the two main characteristics of weak solutions—the apparent quasi-gaseous independence of the dissolved substance in dilute solutions, and the approximately accurate results which are obtained when calculations are based on the assumption that electrolytes in dilute solutions are dissociated into their ions. However important the service rendered to science by the gaseous and dissociation theories of solution, there are many fundamental objections which militate against their universal acceptance. They offer no satisfactory explanation of why substances dissolve at all, and still less why water alone, of all ordinary solvents, should resolve salts, &c. into their ions. These ions are represented to be atoms charged with enormous electric charges, but no explanation is given of the origin of these charges, or of the peculiarities which they are supposed to exhibit; two atoms oppositely electrified are represented as being less combined than when not charged at all; the charged atoms are represented as swimming about in the water without decomposing it, and without giving up their charges to their oppositely electrified companions, although they can part readily with them to an electrode; and to explain the thermal phenomena of solution, it has to be boldly assumed that the decomposition of molecules (elementary or composite) into charged atoms often evolves a considerable amount of heat, and consequently that the charging of an ordinary atom must be a process which evolves heat also. The only crucial experiment which has so far not been susceptible of an opposite interpretation seems to disprove any real dissociation of electrolytes. The lowering of the freezing-point of a solvent is accepted as affording a measure of the number of acting units (molecules or ions) in any substance added to it, and when, for instance, to some acetic acid a weak solution of sulphuric acid is added, the depression produced proves that the latter contains fewer acting units than the water and sulphuric acid do separately, instead of more, as

would be the case if the sulphuric acid molecules had to be split up into independent ions.

In a paper in the *Berichte*, Pickering has offered an explanation of the behaviour of dilute solutions based on the hydrate theory and on the views held by him as to residual affinity. The explanation may be rendered more intelligible by representing chemical attraction, as we represent electrical attraction, to be due to 'charges' on the surfaces of the attracting matter, but inalienable from the matter, owing to a repulsive force between the atoms similar to that which produces elasticity preventing the atoms ever coming close enough together to allow of the charges combining. The charges are represented as being always self-attracting. Each atom possesses one or more unit affinity-charge according as it is a monad or a polyad: with a free atom the charge would be uniformly distributed over its surface, whereas when two atoms are combined the greater part of the charges would be drawn to those sides of the atoms facing each other; but, as in the case of electric charges, a certain amount would still be left on the further sides capable of acting on, and being acted on by, other atoms or molecules in like condition, this residue, or unbound charge, forming what appears as residual affinity. As in the case of electrical charges, the nature of the matter composing different atoms will cause different degrees of mobility in the charges on their surfaces, and hence different pairs of atoms will be held together with different degrees of firmness, and different molecules will exhibit different amounts of residual affinity. When a molecule A B, possessing a certain amount of residual affinity, is surrounded by a number of other molecules C D possessing residual affinity also, the two residual charges will react on each other and increase the amount of the charges on the external portions of the molecules, leaving a smaller amount of charge on the portions of A and B which face each other; in the same way the charge on C will be partially withdrawn from the surface facing D, and will be able to retain a smaller amount of D's charge on the portion of D which is next to it, so that D will exhibit more residual affinity than formerly, and will be able to react in a similar manner on its neighbours, C' D'. Thus, by a process precisely analogous to electric induction, the number of molecules of C D which are acted on by, and are more or less combined with, A B may be very large, and far greater than the number which are capable of coming into its immediate vicinity. The existence of the very complex hydrates which have been recognised in dilute solutions is thus easily explicable. It is evident that a molecule when thus surrounded by, and combined with, a large number of solvent molecules will be attracted equally in every direction, and as the magnitude of the force exerted on it by each individual solvent molecule must be very small, it will be able to move easily in any direction, especially as any of the solvent molecules from which it parts during the process will have their places supplied at once by other similar molecules, of which, owing to continuous dissociation and recombination, there is an abundant supply in the liquid. Thus, into whatever new position the

central molecule moves, the *status quo ante* is immediately reproduced, and, consequently, the molecule will move almost unfettered by the presence of the solvent, and will act almost as if it were in the gaseous state. We thus obtain at once an explanation of why the application of the ordinary gaseous laws to dilute solutions yields very nearly true results; we should, indeed, expect that they would not be absolutely true, for certain definite numbers of solvent molecules would be capable of a more symmetrical arrangement about the central molecule than others, and such arrangements (definite hydrates) would be more stable than others, and the tendency to form them might have an appreciable effect on the regularity of the results: small irregularities of this sort are exactly what we find in the case of those dilute solutions which have been fully examined.

It is obvious that as the quasi-gaseous freedom of the molecule is dependent on its being combined with the solvent, this freedom obtains only so long as the molecule remains within the solvent, and would not admit of the possibility of its leaving the liquid, or of exerting an external gaseous pressure; for the same reason it would be impossible for it to pass through any crevice so small as not to allow it to retain as many solvent molecules as it was combined with in the solution. This gives us an explanation of the action of semipermeable diaphragms and all the phenomena of osmotic pressure; it, moreover, removes a difficulty which must be experienced in accepting the explanation given by the supporters of the physical theory of the action of these diaphragms—why it is that the water molecules (which are admittedly combined in great part into complex aggregates) can so easily pass through interstices which are impervious to what are held to be the single free molecules and ions of the dissolved substance. Direct experiment would seem to decide conclusively in favour of the explanation of osmotic pressure given above, for, when a suitable solution in a porous pot is immersed in either of the substances which compose the solution, osmosis through the pot towards the solution occurs in both cases, showing that osmotic pressure is not due to the impermeability of the pot to either of the constituents of the solution, but to its impermeability to the solution as a whole.

In a case where the atoms of the dissolved molecule possessed a considerable amount of residual affinity, the action and reaction between them and the solvent molecules would, in every respect, be proportionally great, and, consequently, those portions of the whole charges which are utilised in uniting the component atoms of the dissolved substance would be reduced, and, in extreme cases, might be reduced to the lowest possible limits—that is, till the amount of affinity utilised in holding them together was equal to that utilised in attaching them to the solvent molecules, in which case there would be an equal distribution of the affinity charges over the atoms. The atoms composing a molecule in such a condition would have a great amount of freedom of motion within the molecule; being attracted equally in all directions, they would be at liberty to start to

move in any direction, and their movements might attain considerable amplitude under suitable conditions as to the rate at which the forces between them varied with the distance; for to explain the apparent independence of the atoms, and therefore the abnormal osmotic pressure of a salt molecule, 'it only requires,' according to Fitzgerald, 'the space within which [the atoms] are bombarding about to be small compared with the space rate of variation of the force between [them].' The atoms of the two molecules in such a condition would obviously change partners very readily during collision, and this gives us an explanation of why such an interchange does take place when two different salts, &c., are mixed. This ready exchange, moreover, would take place continuously, and in a definite direction, under the influence of any external force, such as a charged electrode, a Grothüss' chain being formed, and we should consequently expect to find that substances in this condition—i.e. those which give abnormally large osmotic pressures—were electrolytes; this is so; and since, moreover, the amount of electrolysis occurring in a given time under a given force would be proportional to the number of molecules in the condition postulated, it follows that this number—and, therefore, the osmotic pressure—could be calculated, at any rate approximately, from the conductivity. In short, whatever calculations hold good on the assumption that the atoms in the molecules are absolutely independent will also hold good if they are assumed to be in the peculiar condition of combination here described—a condition which is brought about by their great tendency to combine with the solvent, and not by a tendency to part company for no assignable reason. On the present view also it is possible to understand why it is that salts and acids are generally electrolytes, and why water is the solvent which makes them electrolytes, for both salts and water are composed of elements which have a strong attraction for elements of an opposite character, and in such a case the residual affinity of both the elements (basyous and chlorous) constituting the salt would be acted on by that of the two opposite elements constituting the water, and we would get an amount of mutual reaction which would be impossible in the case of other substances.

**SONNENSCHEN'S REAGENT.** Prepared by adding phosphoric acid to a warm solution of ammonium molybdate in nitric acid, boiling the pp. with aqua regia to destroy  $\text{NH}_3$ , evapo-

rating to dryness, and dissolving in 10 p.c. nitric acid (A. 104, 45). This reagent gives yellow pps. with alkaloids.

**SOPHORIN.** S. -009 in the cold; .5 at 100°. S. (alcohol) .8 in the cold; 7 at 78°. Obtained from Chinese yellow berries, the undeveloped flower buds of *Sophora japonica* (Stein, *J. pr.* 58, 899; 85, 351; 88, 280; Spiess a. Sostmann, *J.* 1865, 587; Förster, *B.* 15, 216). Decomposed by boiling dilute  $H_2SO_4$  into isodulcitol and yellow sophorstin, which resembles quercetin.

**SOPHORINE.** An alkaloid obtained from the pods of *Sophora speciosa* (Wood, *Ph.* [3] 8, 1047). Liquid, forming a crystalline hydrochloride, which gives a deep-red colour with  $FeCl_3$ . Poisonous. A poisonous alkaloid may also be obtained from the seeds of *Sophora tomentosa* (Greshoff, *B.* 23, 3539).

**SORBIC ACID**  $C_6H_8O_4$ , i.e.  $CH_2=CH\cdot CH=CH\cdot CH_2\cdot CO_2H$ . Mol. w. 112. [134.5°]. (223°). H.C. 730,000 (Ossipoff, *J. R.* 20, 650). Heat of neutralisation: Gal a. Werner, *B.* [2] 46, 802). Occurs in the juice of unripe mountain-ash berries (Hofmann, *C. J.* 12, 43; A. 110, 129). The juice is partially neutralised with milk of lime, decanted from acid calcium malate, and distilled after addition of  $H_2SO_4$ . Needles (from dilute alcohol), v. sol. alcohol and ether, in. sol. hot water, volatile with steam. Partially decomposed on distillation (Barringer a. Fittig, *A.* 161, 307). Has no odour. Br in  $CS_2$  forms tetra-bromo-hexoic acid [179°] and di-bromo-hexenoic acid [90°-95°]. Fuming  $HBr$  forms di-bromo-hexoic acid [68°] (Stahl, *B.* 9, 120). Very dilute alkaline  $KMnO_4$  at 4° gives aldehyde, racemic acid, oxalic acid, and  $CO_2$  (Doebner, *B.* 23, 2376). Sodium-amalgam forms hydrosorbic acid.

Salts.— $BAA'_2$ .— $CAa'_2$ : silvery scales.— $AgA'$ : white crystalline pp.

Ethyl ether  $EtA'$ . (195.5°). Liquid.

Chloride  $C_6H_8O_4Cl$ . Converted by  $NH_3$  and aniline into crystalline  $C_6H_8O_4NH_2$  and  $C_6H_8O_4NHPH$  respectively.

Hydrosorbic acid v. HEXENOIC ACID.

Isosorbic acid v. HEXINOIC ACID.

Reference.—Oxy-SORBIC ACID.

**SORBINOSE**  $C_6H_{12}O_6$ , i.e.

$CH_2(OH)\cdot(CH_2OH)\cdot CO\cdot CH_2OH$  (?). S.G. 1.654.  $[a]_D = -47^\circ$  at 7°. S. 200. An unfermentable sugar obtained from the fermented juice of mountain-ash berries (Pelouze, *A. Ch.* [3] 35, 292; Bysschl, *J.* 1854, 664; Delils, *C. N.* 24, 75). The juice is left to stand for a year, and then filtered and evaporated. Trimetric crystals, as sweet as cane sugar. Levorotatory. V. e. sol. water, sl. sol. hot alcohol. Forms with  $NaCl$  a compound crystallising in cubes. Its aqueous solution dissolves  $CaO$ ,  $PbO$ , and  $Cu(OH)_2$ . Not attacked by  $Br$ . Yields tri-oxy-glutaric acid on oxidation by  $HNO_3$  (Kiliani a. Scheibler, *B.* 21, 8276), but no mucic or saccharic acid (Tollens, *A.* 249, 222).  $HIAq$  and  $P$  yield hexyl iodide. Reduced by sodium-amalgam to sorbite (Vincent a. Delachanal, *C. R.* 111, 52). Not turned brown by hot alkalis. Reduces Fehling's solution. Bromine water yields glycolic acid (Hlasiwetz a. Habermann, *A.* 155, 120). On heating sorbinose (1 pt.) on the water-bath with a solution of phenyl-hydrazine hydrochloride (2 pts.) and  $NaOAc$  (3 pts.) in water (10 pts.) it

Vol. IV,

yields the osazone  $C_{11}H_{12}N_4O_4$  [164°], which crystallises in yellow needles, sl. sol. hot water, v. sol. alcohol, v. sl. sol. ether (Fischer, *B.* 17, 582; 20, 827).

**SORBITANNIC ACID.** Obtained from the berries of *Sorbus aucuparia* (Vincent a. Delachanal, *B.* [2] 47, 492). Gives a yellow colour with alkalis; reduces silver salts in the cold; is not p.p.d. by alum or gelatin. Potash-fusion forms protocatechuic acid and phloroglucin.

**SORBITE**  $C_6H_{12}O_6$ . Mol. w. 182. [111°].  $[a]_D = -1.73^\circ$ . Occurs in mountain-ash berries (Boussingault, *A. Ch.* [4] 26, 376); in plums, cherries, and the fruits of nearly all the *Rosaceae* (Vincent a. Delachanal, *C. R.* 108, 147; 109, 678; 111, 52). Formed on reduction of sorbin and of *l*-gulose (Fischer a. Stahel, *B.* 24, 2144). Formed also, as well as mannite, by reducing glucose (dextrose) with sodium-amalgam in the cold (E. Fischer, *B.* 23, 3684; Meunier, *C. R.* 111, 49). Pearly crystals (containing  $\frac{1}{2}aq$ ). Melts at 75° when hydrated. V. sol. water and hot alcohol. Neither ferments with yeast nor reduces Fehling's solution. Levorotatory, becomes dextrorotatory on addition of sodium borate (Vincent a. Delachanal, *C. R.* 108, 354).  $HIAq$  yields ( $\beta$ )-hexyl iodide (Hitzemann a. Tollens, *B.* 22, 1048). Boiling with  $Ac_2O$  and some  $ZnCl_2$  forms a hexa-acetyl derivative. Benzoic aldehyde and a little hydrogen chloride give  $C_6H_8O_4(C_6H_5O)_2$ , crystallising in rectangular prisms [ $c$ . 175°]; if more acid is present the insoluble compound  $C_6H_8O_4(C_6H_5O)_2$  [162°] is formed (Meunier, *C. R.* 108, 148; 110, 577; *A. Ch.* [6] 22, 423). In like manner valeric aldehyde and  $HClAq$  form, on shaking,  $C_6H_8O_4(C_6H_5O)_2$ , crystallising in prisms, sol. alcohol and ether. Sorbite may be oxidised to glucose by heating in sealed tubes with bromine-water at 60° and treating the product with  $Pb$  and  $PbO$  (Vincent a. Delachanal, *C. R.* 111, 53).

**SORDIDIN**  $C_{12}H_{16}O_8$ . [180°]. A neutral crystallisable substance occurring in the lichen *Zecora sordida* (Paterno, *J.* 1875, 863). Insol. water, v. sol. alcohol and ether.

**SPARTEINE**  $C_{12}H_{18}N_2$ . Mol. w. 234. (811° at 723 mm.) (Bamberger, *A.* 235, 869).  $[a]_D = -14.6^\circ$  at 26° (Bernheimer, *G.* 13, 451). Occurs in the common broom, *Spartium scoparium* (Stenhouse, *A.* 78, 1; Mills, *C. J.* 15, 1). Prepared by extracting the plant with water acidulated with  $H_2SO_4$ , evaporating, and distilling with  $NaOMeAq$ . The distillate is acidified by  $HCl$ ; evaporated to dryness; and the residue distilled with solid  $KOH$ . The base is finally rectified over sodium. Heavy oil, with peculiar odour and bitter taste, sol. alcohol and ether, insol. benzene and ligroin (Houdé, *Fr.* 25, 568). Levorotatory. Turns brown in air. Alkaline in reaction. Narcotic poison.

Reactions.—1. Yields ( $\gamma$ )-methyl-pyridine on distillation with lime (Ahrens, *B.* 21, 826).—2.  $HIAq$  at 200° yields  $MeI$  and  $C_6H_5N_3$  (276°), which forms a platinumchloride [230°], an aurochloride [157°], and a nitrosamine.—3. On passing the vapour through a red-hot tube it gives pyridine, ( $\gamma$ )-methyl-pyridine,  $C_2H_4$ , propylene,  $NH_3$ ,  $HCl$ , and other bodies.—4.  $H_2O$  forms a base  $C_{12}H_{18}N_2O$ .

Salts.—The hydrochloride is amorphous.— $B'H_2PtCl_2$  2aq. Decomposed by boiling

K K

water (Oechsner De Coninck, *Bl.* [2] 45, 181).— $B''2H\text{AuCl}_4$ . Decomposed by boiling water.— $B''HI$ : tables, m. sol. cold water.— $B''H_2ZnI_4$ .— $B''I_4$ : green needles (from alcohol), insol. cold water.— $B''H_2SO_4$ : prisms.— $B''2C_6H_5N_3O_4$ .

*Methylo-iodide*  $B''MeI$ . Trimetric plates;  $a:b:c = .899:1:1.601$ .

*Ethyl-iodide*  $B''EtI$ . Prisms (from water), v. e. sol. water and alcohol, insol.  $NaOH\text{aq.}$ — $B''EtHI$ . Got by heating sparteine with  $EtI$  and alcohol at  $100^\circ$ . Prisms (from cold alcohol). Not coloured by alcoholic potash (De Coninck, *C. R.* 104, 513). Yields  $B''EtClHClPtCl_4$ .

*Dihydride*  $C_{11}H_{22}N_4$ . (283°). Got by reducing sparteine with tin and  $HCl$  (Ahrens, *B.* 20, 2219). Colourless oil.— $B''HCl$ : very deliquescent needles.— $B''H_2PtCl_4$ . Blackens at  $239^\circ$ .— $B''H\text{AuCl}_4$ . Blackens at  $130^\circ$ .—Picrate. [125°]. Needles, decomposing at  $215^\circ$ .— $B''HgCl_4$ .

*Oxysparteine*  $C_{11}H_{22}N_4O$ . [84°]. Formed by oxidising sparteine, and extracting the solution with chloroform (Ahrens, *B.* 24, 1095; 25, 3607). White hygroscopic needles, v. sol. water, alcohol, and ether. Its solution is strongly alkaline. Reduces hot Fehling's solution.— $B''H_2Cl_4\text{aq.}$  Needles, v. sol. water.— $B''HCl\text{aq.}$ — $B''H_2PtCl_4\text{aq.}$  Decomposed at  $209^\circ$ .— $B''H_2PtCl_4\text{aq.}$  Needles: decomposed at  $223^\circ$ .— $B''H\text{AuCl}_4$ .—Mercury double chloride [58°].— $B''HBr_2\text{aq.}$ — $B''HBr_3\text{aq.}$ — $B''HI\text{aq.}$ — $B''HNO_3\text{aq.}$ —Picrate [176°].

*Methyl-iodide of oxysparteine*  $B''MeI$ . [193°].— $B''MeCl$ .— $B''MeClHClPtCl_4\text{aq.}$  [229°].  $POCl_3$  at  $150^\circ$  converts oxysparteine into an oily base  $C_{11}H_{22}N_4$ , which yields  $C_{11}H_{22}N_4.2H\text{AuCl}_4$  [161°].

*Di-oxysparteine*  $C_{11}H_{22}N_4O_2$ . [129°]. Formed by dissolving sparteine in aqueous  $H_2O_2$  (Ahrens, *B.* 20, 2220; 25, 3609). Prisms, v. e. sol. water and alcohol, sl. sol. benzene, insol. ether. Alkaline in reaction.— $B''H_2PtCl_4$ . Blackens about  $235^\circ$ .— $B''H\text{AuCl}_4$ . [c.  $146^\circ$ ]. Needles.— $B''HI$ . [137°].— $B''HBr$ . [147°].— $B''H_2HgCl_4$ . [193°].

*Tri-oxysparteine*  $C_{11}H_{22}N_4O_3$ . Formed by action of  $H_2O_2$  on oxysparteine. Crystalline, v. sol. water and alcohol.— $B''H_2PtCl_4.3\text{aq.}$ — $B''H\text{AuCl}_4$ . [137°].

**SPECIFIC GRAVITY v. DENSITIES, RELATIVE,** vol. ii. p. 370.

**SPECIFIC VOLUMES.** The molecular weights of substances when divided by their respective specific gravities, taken under comparable conditions, furnish values which have been termed *atomic*, *molecular*, or *specific volumes*. The specific volume is, therefore, the space occupied by aggregates of atoms, including the interstitial spaces, whose weights are proportional to the molecular weights of the substances.

Objection has been raised against the term 'specific volume' on the ground that, as specific gravity is the weight of unit volume, specific volume should by analogy be the volume of unit-weight; hence of late years the term 'molecular volume' has been preferred. The term 'specific volume' has, however, acquired by definition and use a distinctive meaning. The adoption of the term 'molecular volume' is almost certain to be attended with confusion, owing to the different sense in which it is frequently employed by

physicists and chemists. The specific gravity of solids and liquids, referred to water at  $4^\circ$ , is the weight in grams of the unit volume. If, then, the molecular weight be expressed in grams, we may define the specific volume of a solid or liquid substance as the number of cubic centimetres occupied by this mass.

The specific gravity of a gas is usually referred to hydrogen as unity. It follows, then, from the law of Avogadro that all gases should have the same specific volume. There are a few exceptions to the universal truth of this statement arising from so-called abnormal vapour densities, but the specific volumes of the exceptional substances stand in the same simple relation to the normal value that their molecular weights stand to what analogy would indicate as the normal molecular weight.

Inasmuch as the specific gravity of a substance is affected to a greater or less extent by heat, it is obviously necessary to determine this constant under comparable conditions of temperature—that is, at temperatures at which heat may be supposed to exercise the same effect on the substance. In the case of liquids Schröder suggested that temperatures at which the vapour pressures of the various liquids are the same—as, for example, their boiling-points under a standard atmosphere—should be regarded as comparable.

In the case of solids the effect of temperature is of course much less marked, and hence the specific gravity of these substances is usually taken at the ordinary temperature of the air.

#### Specific volumes of solids.

The first attempt to trace relationships between the chemical nature of substances and their equivalent volumes appears to have been made by Le Royer and Dumas in 1821 (*J. Ph.* 92, 408). They sought to determine the equivalent volumes of the elements by dividing their atomic weights by their respective specific gravities, the values so obtained being termed by them *atomic volumes*. They were led to infer that these volumes formed an arithmetical series—a supposition which was hardly warranted by the facts then known, and which has since been completely disproved by more accurate observations. This idea of combination among solids in definite volumetric proportion was further developed in 1824 by W. Herapath (*P. M.*, Nov. 1824), who sought to prove that the volume of the oxygen in a metallic oxide bears a simple ratio to that of the metal with which it is combined. Almost simultaneously the same problem was attacked by Karsten (*S.* 65, 394), and subsequently, in 1830, by Boullay, but with no definite general result.

Ammermüller, however, in 1840, concluded (*P.* 49, 341; 50, 406) that the specific volumes of compounds containing the same elements in different proportions are either identical or stand to one another in rational proportions. Persoz in his 'Introduction to the Study of Molecular Chemistry,' recognised that equivalent amounts of many bodies of analogous composition occupy the same volume, and he inferred that the specific volumes of all substances are multiples of one and the same number, a conclusion also drawn by Le Royer and Dumas, but which is not supported by facts.

Kopp (*P.* 47, 138), in 1839, first attempted to

deduce general formulæ from which he was able to calculate the specific gravities of certain oxides and haloid salts, with results which showed, in general, a fair agreement with the observed values. In the same manner he calculated formulæ for other anhydrous salts—such as sulphates, carbonates, and nitrates—on the supposition that such salts consist of combinations of oxides and acids, or that they are made up of a radicle, acid *plus* oxygen. By means of these formulæ he inferred that it is possible to draw conclusions concerning the specific gravity of metals for which this constant is unknown. Kopp, in this memoir, used the term *specific volume* for the first time, and he defined it as the molecular weight (*Mischungsgewicht*) of a substance divided by its specific gravity. He found that the specific volumes of similarly reactive elements—as, for example, chlorine, bromine, and iodine; tungsten, molybdenum, chromium, iron, manganese, nickel, cobalt, &c.—are equal or nearly equal. In other cases—as silver and gold, potassium and sodium—the specific volumes stand to each other in simple relations. Elements which, like barium and strontium, form isomorphous compounds have the same specific volume. Strictly speaking, this law can hold only for those substances which are perfectly isomorphous. The more nearly the crystalline forms of isomorphous substances are identical, the more nearly will their specific volumes be the same. This is made evident by a comparison of the axial ratios of *witherite*, *strontianite*, *aragonite*, and *cerussite*; and also of the carbonates of zinc and magnesium (*mesitene*), the carbonates of iron and manganese, and *dolomite* and *calc-spar*. It is seen that there is a direct comparison in the case of the latter compounds between the length of the principal axis  $a$  and the specific volume  $V$ , such that  $a^{4.789} = 0.0127671V$ , from which it is possible, of course, to deduce the specific gravity of the substance from its crystalline form. It also follows that an increase of specific volume is occasioned by an increase in the length of the axis  $a$ . If we heat one of these crystals the density decreases; the axis  $a$  must therefore increase in length, while the angle  $R$  becomes less obtuse. This fact, indeed, was discovered by Mitscherlich, who found that the specific gravity of calc-

spar decreased in the ratio of 1 to  $\frac{1}{1.001961}$  when

calc-spar was heated through  $100^\circ$ . The specific gravity of calc-spar is 2.7220, when  $\alpha = 0.8544$  and  $R = 105^\circ 5'$ . By heating calc-spar through  $100^\circ$ , the specific gravity becomes 2.7167, or the specific volume changes from 36.73 to 36.80. If we determine the length of the axis  $a$  by means of the above formula, we find it to be 0.85672, corresponding to an angle  $R$  of  $104^\circ 57'$ , or a difference of  $8'$ , which closely agrees with that actually observed by Mitscherlich (*P. M.* [3] 18, 255). Schröder (*P.* 1840, 553), starting from the observation of Ammermüller, that equal volumes of the two oxides of copper contain the same amounts of copper and multiple amounts of oxygen, assumed that the volume of the copper, as of the oxygen, is equal in the two substances, but that the amount of the oxygen in the cuprous oxide stands to that in the cupric oxide as 1 to 2.

Hence Schröder drew the general conclusion that the same element can have different specific volumes in different compounds, but that the several values for the specific volumes stand in simple relations to each other. He saw in this hypothesis not only an explanation of the condensation which accompanies chemical union, but also a rational basis for the belief that the specific volume of a compound is equal to the sum of the specific volumes of its components.

Schröder found that if in a series of analogous bodies, AO, BO, CO, the specific volumes of which are known, we subtract from these values the primitive atomic volumes of A, B, and C respectively, we obtain a constant remainder. This he found to be the case with the oxides of lead, cadmium, and zinc, and hence he inferred that the metal in these oxides retains its primitive atomic volume. Kopp assumed that this is equally true of the salts of the heavy metals, but with the salts of the metals of the alkalis and alkaline earths this is impossible, as the specific volumes of the salts are, as a rule, smaller than the primitive atomic volumes of the component metals. He had consequently to assume for these metals a special atomic volume, which however, remains the same in all the salts. He determined these values as follows: Suppose  $M + R$  to be a compound of a heavy metal, and  $m + R$  the analogous compound of a light one; suppose  $A$  to be the known specific volume of  $M + R$ , and  $a$  that of  $m + R$ ,  $B$  the primitive atomic volume of  $M$ , and  $b$  that of  $m$ .

$$\begin{aligned} \text{Then, } M + R &= A, \\ \text{and } m + R &= B. \end{aligned}$$

Therefore the atomic volume with which  $R$  is contained in the compound is  $A - B$ , say  $x$ .

It is assumed that  $R$  retains its value in  $m + R$ ,

$$\begin{aligned} \text{and since } m + R &= a, \\ \text{and } R &= x; \end{aligned}$$

therefore  $b$ , i.e. the atomic volume of  $m = a - x$ .

Kopp also showed that the densities of the hydrated oxides, and of a number of hydrated salts, may be calculated with considerable accuracy by assuming certain definite values for water in a state of combination. It ought to be stated, however, in this connexion, that subsequent researches have indicated that Kopp's conclusions respecting the specific volume of water of crystallisation must be slightly modified. Schiff, many years ago, showed that the members of certain classes of hydrated salts have practically the same specific volume. Thus, all the alums have a specific volume of about 277; double sulphates of the form  $M_2M''(SO_4)_6 \cdot 6H_2O$  have a common volume of 207; and all the vitriols—that is, salts of the form  $M''SO_4 \cdot 7H_2O$ —whether isomorphous or not, have the specific volume 146.

Thorpe & Watts (*C. J.* 37, 102, [1880]) have shown that the volumes occupied by the several molecules of water vary with the degree of hydration of the salt. In the case of the so-called magnesian sulphates, the first molecule of water, the constitutional water, or 'water of halhydration' of Graham, occupies considerably less bulk than the remaining molecules; its mean relative value is 10.7. Each additional molecule appears to occupy a gradually increasing volume. The difference between the specific volumes of

the monohydrate and dihydrate is 13.8; between the volumes of the dihydrate and trihydrate the difference is 14.5; between the trihydrate and the tetrahydrate it is 15.4; and between the hexahydrate and heptahydrate it is 16.2. These observations are so far in harmony with Kopp's general conclusions that in the compounds containing only a small number of water molecules (1 to 3) the specific volume of the water is 12.4; in others containing a larger number of molecules of water (2 to 7) it is 13.4; whereas, in a third class, containing the largest number of molecules of water (from 8 to 10), its mean value is 15.3.

#### Specific volumes of liquids.

**Methods.** The specific gravity of the liquid at its boiling-point may be determined either directly or indirectly. Ramsay (*C. J.* 35, 463 [1879]) devised a simple method by which the weight of a known volume of liquid at its boiling-point may be directly ascertained with approximate accuracy. The vessel containing the liquid consists of a thin glass lemon-shaped bulb of about 10 c.c. capacity. At the upper end of the bulb is a capillary tube, bent into the form of a hook; the lower end is provided with a similar hook of solid glass. The capacity of the bulb is ascertained by weighing it full of water at a known temperature. The bulb is filled with the liquid to be examined, in the usual way, by warming and dipping the capillary neck of the bulb beneath the surface of the liquid. It is not necessary to fill the bulb completely; two or three c.c. of the same liquid are then introduced into the wide tube, and the bulb is suspended within it by thin platinum wire attached to a piece of glass rod passing through a hole in the cork. The wide tube is then heated until the liquid within it boils violently, and it is kept in ebullition so long as liquid drops from the end of the capillary neck of the bulb. The lamp is now removed, and the whole allowed to cool. When cold the bulb is dried and weighed. The specific gravity of the liquid is given by the formula

$$\text{Sp. gr.} = \frac{W'}{1 + (0.00015 \times TW)}$$

in which  $W'$  is the weight of the liquid;  $W$ , that of the water filling the bulb at  $0^\circ$ ; and  $T$  the temperature at which the liquid boils; 0.00015 is an empirically-determined, co-efficient required in order to make the volume correspond with the real volume at  $T$ .

A somewhat similar method of determining the specific gravity of a liquid at its boiling-point is described by R. Schiff (*A.* 220, 78). The liquid is introduced into a flask of about 7 or 8 c.c. capacity, provided with a long narrow neck on which is a graduated scale. The capacity of the flask up to the zero point is accurately determined by weighing with mercury, and the value of the scale divisions in fractions of a c.c. is also carefully estimated. The flask is then suspended in the boiling tube; a few c.c. of the liquid under investigation are placed in this tube and heated to boiling. After a few minutes the position of the liquid in the graduated neck is noted, and the flask is withdrawn, wiped, and weighed. The specific gravity

at the boiling-point compared with water at  $4^\circ$  is given by the equation

$$D_4 = \frac{P}{V[1 + K(t-4)]}$$

in which  $P$  = corrected weight of the liquid in the flask,

and  $V$  = the apparent volume of the liquid at  $t^\circ$ ,

$K$  = the co-efficient of expansion of the glass.

It will be noticed that Schiff assumes that the liquid in the flask actually acquires the temperature of the vapour by which the flask is surrounded. Lothar Meyer (*v. Neubeck, Z. P. C.* 1, 652) has slightly modified Ramsay's apparatus. The bulb is best made of Jena glass, and has the capacity of about 2.5 c.c., and its weight, capacity, and thermal expansion are accurately known. It is filled with the liquid, and is suspended by means of a bent platinised-nickel wire within the flask, the neck of which can be closed by a cork. The flask contains a few c.c. of the liquid under investigation, which, when heated, may if necessary be caused to boil at any desired temperature below the ordinary boiling-point by connecting a side tube with a condenser, pressure-regulator, and fall-pump. As soon as the liquid within the bulb has acquired the temperature of the boiling liquid, and no further expansion occurs, the source of heat is removed and the bulb is weighed when cold.

The specific gravity of a liquid at its boiling-point is, however, most accurately ascertained indirectly, although this method demands far more time and apparatus, and a greater number of experimental operations, than the direct method. The method consists in accurately determining (1) the boiling-point of the liquid; (2) the specific gravity of the liquid at some convenient temperature—best at  $0^\circ$ ; and (3) the rate of thermal expansion of the liquid from  $0^\circ$  up to the neighbourhood of its boiling-point. From these data the specific gravity of the liquid at the boiling-point can be readily calculated.

**1. Determination of the boiling-point.** This is best made in an apparatus so arranged that the inner tube, containing the thermometer, is surrounded by a jacket of vapour from the boiling liquid. The boiling liquid should contain a few scraps of platinum foil or a spiral of platinum wire; or, what is even better, a few short lengths of fine capillary tubing. If the amount of the liquid is very small the bulb of the thermometer should be surrounded with a little fibrous asbestos, as suggested by Ramsay & Young (*C. J.* 47, 42). The thermometer reading must, if necessary, be corrected for the emergent column, either by the tables of Rimbach (*B.* 22, 3072) or by that of Thorpe (*C. J.* 37, 159), and should be reduced to normal pressure by the method of Crafts (*B.* 20, 708). The correction to standard atmosphere may, however, be ascertained with approximate accuracy by the formula

$$\theta = (p - 760) \frac{278 + t}{8200}, \text{ or } \theta = (p - 760) \frac{278 + t}{10000},$$

in which  $\theta$  is the correction,  $t$  the observed boiling-point, and  $p$  the barometric pressure reduced and corrected.

The first correction is applicable to the

greater number of liquids, the second to water and the lower alcohols (Ramsay & Young, *P. M.* 1885, 515).

2. *Determination of specific gravity.* This is most accurately effected, at least for substances which are liquid at ordinary temperatures, by Perkin's modification of the Sprengel apparatus. For liquids which are alterable on exposure to air a bottle with a graduated stem is most convenient. The bottle should be previously filled with dry nitrogen, and a special apparatus, analogous to that used by Thorpe (*l.c.*) must be employed to transfer the liquid to the bottle. A form of bottle for very viscid liquids has been described by Brühl.

3. *Determination of thermal expansion.* Of the various modes of ascertaining the thermal expansion of a liquid the so-called dilatometrical method is, on the whole, the most convenient. It consists in inclosing the liquid in a vessel of known capacity, shaped like a thermometer, and provided with a graduated and accurately calibrated stem. The instrument is placed in a bath of suitable liquid, the temperature of which can be raised to the desired point, as ascertained by a thermometer; and the height of the liquid in the stem of the dilatometer, and hence its apparent volume at the temperature of observation is noted. A series of such observations at various temperatures up to the neighbourhood of the boiling-point is thus made, from which an expression, say of the form  $V_t = a + bt + ct^2 + dt^3 \dots$ , may be calculated. This expression must now be corrected for the expansion of the glass of the dilatometer (obtained by observations with mercury in the usual manner), and from the corrected expression the volume, and hence the specific gravity, at the boiling-point of the liquid may be deduced.

For details of the mode of carrying out these observations v. Kopp (*A. 96, 1 et seq.*); Thorpe (*C. J.* 37, 141).

Thorpe (*C. J.* 63, 262 [1893]) has devised a modification of the ordinary dilatometrical method, which permits the thermal expansion of a liquid to be determined with much greater ease and rapidity than has hitherto been possible. It obviates the use of large baths, and, by reducing the size of the dilatometers to the smallest limit consistent with the proper degree of accuracy, as determined by the error of a thermometer reading, it avoids the necessity for long stems and the consequent correction for the cooled 'emergent columns.'

*Results.*—The first accurate determinations of the various physical constants needed to ascertain the specific volumes of liquid substances were published by Kopp in 1855 (*A. 96* [1855] 1-36, 153-185, 303-335; *A. 100* [1856] 19-38; v. also *P. 72* [1847] 1-62, 176, 223-293). Kopp concluded, from the results of a long series of observations, that:—

(1) The selection of the temperature of equal vapour-pressures as a basis of comparison seemed to be warranted by the fact that regularities are thereby made evident which otherwise are not apparent.

(2) Differences of specific volume are proportional to differences in chemical composition.

(3) Isomeric liquids of the same chemical type have equal specific volumes.

(4) The substitution of hydrogen for an equivalent amount of oxygen only slightly affects the specific volume.

(5) One atom of carbon can replace two atoms of hydrogen without altering the specific volume of the compounds.

Kopp further found that the specific volume of a liquid compound was conditioned, not only by the composition, but also by the constitution of the compound. Thus the relative position of an oxygen atom in a molecule affects its specific volume; carbonylic oxygen and hydroxylic oxygen have two very different values. Sulphur, in like manner, would appear to have two specific volumes, depending on its position or mode of combination in a molecule.

Definite values for the specific volumes of carbon, hydrogen, and oxygen were obtained from the following considerations. An increment of  $\text{CH}_2$  corresponds to an increase of specific volume of 22. Since C and  $\text{H}_2$  occupy the same volume, we have  $\text{C} = 11$  and  $\text{H} = 5.5$ . The replacement of  $\text{H}_2$  by carbonylic O is attended by a slight increase in the specific volume. Kopp found that the most probable value for O in this form of combination was 12.2. For hydroxylic oxygen it is 7.8; obtained by subtracting the value for  $\text{H}_2$  (11) from the specific volume of water, 18.8. Hence the specific volume of a compound  $\text{C}_a\text{H}_b\text{O}_c\text{O}'_d$ , where O is carbonylic oxygen and O' is hydroxylic oxygen, may be expressed by the formula

$$V = 11.0a + 5.5b + 12.2c + 7.8d.$$

Determinate values for the specific volumes of the halogens—and, with less precision, for phosphorus, arsenic, and antimony, for silicon, titanium, and tin—were also obtained by Kopp. As regards nitrogen it was found that in the amines  $\text{N} = 2.3$ . The group  $\text{CN} = 28$ ; the group  $\text{NO}_2 = 33$ . If, then, carbon and oxygen preserved their ordinary values in these radicles N must possess at least three different values depending on the mode of combination. There is, however, no evidence to disprove the supposition that the values for the carbon and oxygen atoms are not equally affected in these groups. This, indeed, suggests the possibility that compound radicles like CO, HO,  $\text{NO}_2$ , CN, &c. may possess definite specific volumes which are not necessarily the sum of the specific volumes of the component atoms as ordinarily ascertained.

H. L. Buff (*A. Suppl.* 4, 129) sought to show that the specific volume of carbon, like that of oxygen and sulphur, is affected by its mode of combination—or, in other words, that carbon in unsaturated compounds has a greater specific volume than in saturated bodies—from which he surmised that the specific volume of an element is in general determined by its particular atomic value. Thorpe (*C. J.* 87, 892) found that isomeric liquids have not invariably the same specific volumes. There is a well-marked difference, for example, between ethylene and ethidene chlorides; indeed, ethylene compounds in general appear to have smaller volumes than those calculated by Kopp's values. Stadel has shown that in the series of chlorinated and brominated ethanes and ethylenes, the isomeric of higher boiling-point, i.e. the ethylene derivative, has invariably the lower specific volume.

Since these compounds are all saturated, and the only variable constituent is a monovalent element (Cl or Br), it would appear probable that the specific volume of the halogen is also variable. Isomeric hydrocarbons manifest similar differences, whence it is obvious that either one or both of the elements must have a slightly variable volume, depending on grouping or mode of combination; it may be that the iso-group, like the groups carbonyl, hydroxyl, nitril, &c., has a special volume, which is not necessarily the sum of the volumes of the component atoms as deduced from Kopp's values. Kopp himself found that the volumes of isomerides were in a number of cases only approximately equal, and in others quite unequal. The term 'chemical type,' used in the sense in which Gerhardt employed it, is not sufficiently distinctive to denote the differences, say, between the normal and iso-compounds, or between aniline and the picolines, and it is questionable whether Kopp would have considered such cases as coming within his rule.

The observed specific volumes of the aromatic compounds are frequently lower than the calculated values. Indeed, our views as to the constitution of the aromatic compounds would lead us to expect that the specific volume of benzene, and the volumes of the derivatives which contain the benzene grouping, would probably be different from the values deduced from observations made for the most part on compounds of totally different constitution. Kopp (*A. Suppl.* 5, 303 [1867]) showed from Louguine's observations that while benzene has an abnormally low specific volume, its homologues show the constant increase of 22 for an increment of  $\text{CH}_2$ , which is what might be anticipated, since these homologues are produced by the addition (substitution) of methyl, ethyl, &c., to the benzene group. Jungfleisch's observations on the specific volumes of the chlorine substitution products of benzene also seem to show that the positions of the chlorine atoms affect, in a very marked manner, the specific volume of the product (*C. R.* 64, 911).

Further observation has shown that Kopp's conclusion that liquid elements and radicles have the same volume in combination as in the free state is well founded. Thus the observed volume of  $\text{NO}_2 = 32.0$ , calculated = 31.5; observed volume of  $\text{Br} = 53.6$ , calculated = 53.4; observed volume of  $\text{CN} = 28.9$ , calculated = 28.9. The observed specific volume of Cl from Knietzsch's determinations of the specific gravity of liquid chlorine is 22.8; the mean calculated value is 22.7. Kopp surmised that members of the same chemical family would be found to have the same specific volume; observation shows, however, that the specific volumes gradually increase with the increase of atomic mass (Thorpe, *l.c.*).

Schiff (*A.* 220, 71 [1883]) has concluded that while it is generally true that isomeric compounds have slightly different specific volumes, it is almost invariably the case that the substance possessing the higher boiling-point has also the higher specific volume (compare Stadel). In the case of the metameric esters of the fatty acids, it is found that, as a rule, the specific volumes increase with the diminution of the number of carbon atoms in the acidic radicle and with the increase of the carbon atoms in the

alcoholic radicle. At the same time, it would appear that the differences between the observed and calculated values are mainly due to the alcoholic radicle, the acidic radicle apparently having but slight influence. This is in conformity with Lossen's observations, that while the ethers and acids give experimental values which are almost in exact accordance with Kopp's values, the aldehydes and alcohols show wider variations, methyl alcohol giving too great an observed value, while the others give smaller and smaller values as the amount of carbon increases. It is, however, noteworthy that the differences between the aldehydes and derived alcohols remain almost constant, which is not the case with the aldehydes and acids, where the difference appears to increase with the molecular weight. Hence the differences between the homologous aldehydes are very nearly equal to those between the corresponding homologous alcohols (Lossen). The mode in which carbon is combined in an organic compound has, according to Schiff, a distinct influence on its specific volume; like Buff, he finds that a doubly linked carbon atom occupies a smaller volume than when singly linked. It is, however, very doubtful whether the facts at present known are sufficient to establish this conclusion.

There is, however, good reason to believe that what we call 'specific volume' is not a purely additive property. The specific volumes of substances are, in all probability, affected by many more conditions than those we have hitherto taken cognisance of. The value  $\text{CH}_2 = 22$  has no other significance than as expressing the average increment in volume in successive members of a homologous series. Indeed, as the physical data increase it becomes doubtful whether even this mean value is correct. It would seem that the value augments as the series is ascended. The relation  $\text{C} = 2\text{H}$  no longer applies to carbon compounds in general. What is true of carbon and hydrogen is equally true of oxygen, whether as carbonylic or as hydroxylic oxygen. No definite or uniform values can be assigned to oxygen such that the specific volume of a liquid compound containing this element can be accurately calculated. The values given by Kopp and others are simply mean values, but the actual volumes are affected by conditions of which, as yet, we have no very precise knowledge and which we have no certain means of measuring. The values for the other elements are, of course, affected by these considerations. Thus the specific volume of chlorine is obtained on the assumption that the values for carbon and hydrogen are constant.

Lossen (*A.* 254, 42) has devised formulae which take note, or express the measure, of the influences which affect the uniformity in the values of specific volumes of organic compounds. These formulae can only be considered as first approximations, but their value will be evident from the fact that they serve to reproduce the observed values with a greater approach to accuracy than has hitherto been possible. Out of the 407 compounds which furnished the experimental material on which these formulae are based, the observed molecular volumes of 352 differ by less than 2 p.c. from the calculated volumes. Comparatively few of these differences are to be ascribed to experimental errors. In

the main they are caused by influences of structure and composition which as yet we have no certain means of measuring, such as the effect of substituted chlorine, or the special effect of iso-grouping, or of the ortho-, meta-, or para-position, &c.

According to Lossen, the specific volumes of the greater number of compounds containing carbon, hydrogen, and oxygen which have hitherto been determined, may be calculated by the formula

$$\text{Sp. vol. } C_n H_m O_p (\mu) = (10.24 \pm \alpha 0.5)(n+p) + (5.12 \pm \alpha 0.25m) \pm \frac{1}{2}(n-2)^2 \pm 1.4\mu$$

In this equation  $\alpha$  denotes a number between 0 and 1, which varies with different homologous series but which is constant for the members of the same series. The sign  $\mu$  represents the number of hydrogen atoms required to convert the formula into that of a saturated compound. The term  $\frac{1}{2}(n-2)^2$  is introduced to compensate for the increase in the value corresponding to  $CH_4$  as the molecular weight increases. Gartenmeister (*A.* 233, 304) having shown that in the case of the fatty esters the mean increase corresponding to  $CH_2$  is 0.5, Lossen adds the term  $(\frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \dots \frac{n-3}{2})$ , which he erroneously states is equal to  $\frac{1}{2}(n-2)^2$ , a number always subsequently employed, but which, as comparison shows, serves to give good agreement with observed values.

For the majority of fatty compounds the formula

$$C_n H_m O_p = 10.45(n+p) + 5.225m + \frac{1}{2}(n-2)^2 + 1.5\mu$$

gives results agreeing with the observed values. For the alcohols, however, the expression becomes

$$C_n H_m O_p = 10.1(n+p) + 5.05m + \frac{1}{2}(n-2)^2 + 1.35\mu.$$

If it be supposed, as seems highly probable, that for all the members of a series of similarly constituted compounds the same influences are existent, whereby the specific volumes exhibit variations from the additive quantities assumed by Kopp, then we may regard the variable  $\alpha$  as a term which takes account, and may be regarded as the measure, of these disturbing influences, and which, though constant for the members of the same series, should, as before stated, vary for other homologous series of compounds (Thorpe & Jones, *C. J.* 63, 289).

Schröder regards the specific volume of an element in combination as variable within limits determined by the nature of the chemical compound. In any one compound, however, all the elementary atoms are regarded as occupying either equal or multiple volumes. Hence every specific volume is a multiple of a certain *space-unit* or *stere*, the value of which may vary between 6.7 and 7.4, depending on the number, nature, and mode of union of the atoms. Schröder thus obtains his determinate values. The specific volumes of formic, acetic, and propionic acids increase about 22 units for each increment of  $CH_2$ ; in the case of alcohols the increase is about 20 units. The volume of formic acid is 41.8, i.e.  $2 \times 20.9$ ; that of methyl alcohol is 42.8 or  $2 \times 21.4$ . Hence in formic acid,  $CH_2O_2$ , the  $O_2$  occupies the same volume as  $CH_4$ ; and in methyl alcohol,  $CH_4O$ , the  $H_2O$  has the same volume as  $CH_4$ . In like

manner ethyl alcohol,  $C_2H_5O$ , has the volume 62.1, i.e.  $3 \times 20.7$ . Since  $2 \times CH_2 = 2 \times 20.7$ , then  $H_2O = 20.7$ . Acetic acid has the volume 63.6, i.e.  $3 \times 21.2$ ;  $2CH_3$  is  $2 \times 21.2$  and  $O_2 = 21.2$ . The volume of acetaldehyde is 56.9, i.e. about 6.6 smaller than that of acetic acid; this would indicate that the substitution of OH by H lowers the volume by 6.6. Since  $H_2O = 21.4$ , it follows that the hydrogen and oxygen in hydroxyl each occupy one space-unit or stere. As  $CH_4 = 21$ , we find that carbon also occupies one stere or space-unit. Now, from the volume of formic acid which contains 6 steres, it is found on subtracting 3 steres for  $CH_4$  and 1 stere for hydroxylic oxygen, that the carbonylic oxygen must occupy 2 steres.

We obtain, then, the following rule: *The number of space-units or steres of the saturated compounds of carbon, hydrogen, and oxygen corresponds to the number of the atoms increased by as many units as there are atoms of carbonylic oxygen present.*

If we calculate by means of this rule the steres of the saturated compounds, we find that they vary within narrow limits, and for the most part increase with increasing molecular weight. In the greater number of cases the values range between 6.9 and 7.2. Ostwald has determined the value of the stere for a large number of saturated fatty compounds, with the following results:—

<i>Hydrocarbons</i>	6.89, 6.99, 6.82, 7.11, 7.23.
<i>Alcohols</i>	7.12, 6.91, 6.77, 6.88, 6.78, 6.78, 6.81, 6.74, 7.09
<i>Acids</i>	6.97, 7.06, 7.11, 7.19, 7.24, 7.24; 6.85.
<i>Esters</i>	7.04, 7.08, 7.05, 7.14, 7.26, 7.43, 7.45, 7.47.
<i>Aldehydes</i>	7.11, 7.05, 7.18, 7.01, 7.18, 6.93, 7.27.

In the series of the hydrocarbons, the acids, and the esters, the steres in the cases of the normal compounds increase regularly with increasing molecular weight; in the series of the alcohols the steres decrease up to the third member and then increase. The secondary and tertiary compounds have, as a rule, smaller steres than the normal compounds. Kopp concluded from the approximately equal volumes of the alcohols and corresponding acids that  $H_2$  and  $O$  are volumetrically equivalent; and from the equivalence of the volumes of benzyl and amyl compounds he inferred that  $C_2$  and  $H_2$  are mutually replaceable without alteration of volume. Hence he assumed that the hydrogen atom occupies only half the volume of the oxygen or carbon atom. Schröder established the volume equivalence of  $CH_4$ ,  $HOH$ , and  $O'O$ , and he inferred from the difference in volume between alcohol and aldehyde that hydroxylic oxygen has the same volume as hydrogen and carbon, while carbonylic oxygen has twice the volume. While, then, Kopp assumes approximately  $H_2 = C = O$ , Schröder makes  $H = C = O$  (Ostwald, *Lehrbuch*, [2nd ed.] vol. i. p. 388).

In the case of unsaturated and aromatic compounds, Schröder assumes that each double linkage is attended with an increase of volume amounting to one stere; hence the above rule has to be modified in this sense when applied to compounds of this class. The value of the stere

in a number of unsaturated compounds is found to be:—

Hydrocarbons . . 6.87, 7.09, 6.93, 6.99.

Alcohols . . . 6.72.

Esters and ethers . 7.14, 7.13.

These values vary, practically, within the same limits as in the saturated compounds.

As regards aromatic compounds, it would seem to follow from the identity in the volumes of benzoyl and amyl compounds, as indicated by Kopp, as well as from the corresponding relation between the isobutyl and phenyl compounds, that  $C_6H_5$  comprises the same number of steres as  $C_4H_9$ —that is, 13. Of these, 5 are occupied by hydrogen; so that the carbon group  $C_6$  occupies 8 steres.

The values of the stere in a number of aromatic compounds are as follows:

Hydrocarbons 6.85, 6.94, 6.98, 7.00, 6.95, 7.04, 7.04, 7.04, 7.06, 6.84

Other compounds 6.91, 6.87, 7.05, 6.97, 7.16, 7.26, 7.50, 7.28, 7.14, 6.96, 7.07.

The value of the stere here also varies within the usual limits; it is comparatively small for the hydrocarbons (6.8–7.0), larger in the case of the alcohols, and still larger in that of the esters (7.2–7.5) (Ostwald, l.c.).

There is one consideration which is vital to the whole question, and to which, therefore, a brief reference must be made. It relates to the choice of conditions under which the values we term specific volumes are really comparable. Although Horstmann and Lossen have advanced reasons against the practice, contending that at any other temperature, say  $0^\circ$ , relations similar to those now established are made manifest, it has been the custom, in accordance with Kopp's direction, to compare the specific volumes of liquids at the temperatures of their respective boiling-points under a standard atmosphere. Whether, however, the temperature of the boiling-point, under these circumstances, is a truly comparable condition is open to question. It has been urged by Horstmann that, since what we call atomic volume is the space not merely filled by an atom but also that in which it moves, it is not *a priori* probable that at temperatures which differ, say by  $300^\circ$ —as, for example, in the case of  $C_6H_6$  (boiling-point  $1^\circ$ ) and  $C_{10}H_{16}$  (boiling-point  $317^\circ$ )—these volumes will be the same. Moreover, as pointed out by Bartoli, the boiling-point cannot in the nature of things be a strictly comparable condition, since it is affected by pressure to a different extent in the case of different liquids. Objections of even greater weight may be urged against the suggestions of Tschermak and Krafft to take the melting-point as a comparable state.

No doubt, theoretically speaking, a valid condition should be when pressure, volume, and temperature are expressed in terms of their critical values. But that certain regularities in the molecular volumes at the boiling-points have, in spite of this, been discovered may be explained, as Guldberg has shown, when we compare the values of  $T$ , the absolute boiling-point, with those of  $T_c$ , the absolute critical temperature; in those cases in which these two constants are known, the ratio  $\frac{T}{T_c}$  approximates

to  $\frac{2}{3}$ . Hence it follows that qualities like molecular volumes, which alter only slowly with temperature, are comparable at the ordinary boiling-points (*Z. P. O.* 5, 374).

It ought, perhaps, to be stated that subsequent observations show that the so-called 'corresponding temperatures' deduced from Van der Waal's generalisations have not that degree of validity as temperatures of comparison which they were originally assumed to possess. Indeed, the present condition of knowledge warrants the statement that Kopp's original method of comparison is as valuable as any yet indicated (Thorpe, *C. J.* 63, 775 [1893]). T. E. T.

**SPECTROSCOPIC ANALYSIS v. PHYSICAL METHODS**, section *Optical methods*, subsection *Spectroscopic methods*, this vol. p. 239.

**SPELTER**. A commercial name for *sinc*.

**SPIERGULIN**  $(C_6H_5O_2)_n$ . Occurs in the seed-coverings of *Spergula vulgaris* and *S. maxima* (Harz, *C. C.* 1879, 24). Amorphous. Its alcoholic solution exhibits dark-blue fluorescence, which is destroyed by sunshine. A small quantity of potash or  $Na_2CO_3$  added to the alcoholic solution causes it to fluoresce green. Conc.  $H_2SO_4$  forms a dark-blue liquid.

**SPEERMINE**  $C_{10}H_{16}N_4$  (Poehl, *B.* 24, 359);  $C_8H_{10}N_2$  (S.). Occurs as phosphate in the spermatic fluid, in calves' liver and heart, and in some pathologic preparations that have been kept under alcohol (Schreiner, *A.* 194, 68). It is not identical with pyrazine hexahydride (Majert, *A. Schmidt*, *B.* 24, 241; cf. Ladenburg, *B.* 20, 442; 21, 758; Poehl, *C. R.* 115, 515; Duclaux, *C. R.* 115, 155, 549). Crystals (from alcohol), v. sol. water, v. sl. sol. alcohol. Alkaline in reaction. Absorbs  $CO_2$  from the air. Its aqueous solution is ppd. by phosphomolybdic acid and by potassium bismuth iodide. —  $C_{10}H_{16}N_4 \cdot 4HCl$ : prisms, v. s. sol. water. —  $C_{10}H_{16}N_4 \cdot 2H \cdot PtCl_6$  —  $C_{10}H_{16}N_4 \cdot 4HAuCl_4$  —  $C_{10}H_{16}N_4 \cdot (H_3PO_4)_2$  6aq:  $[170^\circ]$ ; rosettes of pyramids, sl. spl. hot water.

**SPIKE OIL**. S.G. above .900. Slightly dextrorotatory (Schimmel, *Ph.* [3] 22, 329).  $[\alpha]_D = 1^\circ 24'$  (Voirey, *A. Bouchardat*, *C. R.* 106, 551) or levorotatory (Bruylants, *J. Ph.* [4] 30, 139). An essential oil obtained from the blossoms of *Lavandula aspicia latifolia* (Lallemand, *A.* 114, 197; Sauer, *A. Grünling*, *A.* 208, 75). Smells like lavender. Contains a terpene ( $175^\circ$ ) or ( $158^\circ$ ), which yields crystalline  $C_{10}H_{16}HCl$ , camphor, borneol, and a resin. According to Voirey and Bouchardat, oil of spike contains inactive spikol  $C_{10}H_{16}O$   $[0^\circ]$  and  $C_{10}H_{16}$  ( $155^\circ$ – $160^\circ$ )  $[\alpha]_D = 24^\circ$ , which yields a hydrochloride  $[129^\circ]$   $[\alpha]_D = -2^\circ$ .

**SPIROGRAPHIN** v. **PROTEIDS**, *Appendix C*.

**SPONGIN** v. **PROTEIDS**, *Appendix C*.

**STACHYDRIN**  $C_8H_{13}NO_2$ .  $[210^\circ]$ . Occurs with glutamine, tyrosine, and stachyose in the tubers of *Stachys tuberosa* (Von Planta, *A. Schulze*, *B.* 26, 939). Colourless, deliquescent crystals (from water). Behaves like betaine with regard to alkaloidal reagents. —  $B \cdot HCl$ . Prisms, v. sol. water, sol. cold water (difference from betaine). —  $B \cdot H \cdot PtCl_6$  2aq. Trimetric crystals; *a:b:c* = .608:1:828. —  $B \cdot HAuCl_4$ . Small yellow prisms (from water).

**STACHYOSE**  $C_{12}H_{22}O_{11}$  3aq.  $[\alpha]_D = 148^\circ$ . Occurs in the roots of *Stachys tubrifera* (Planta n. Schulze, B. 23, 1692; 24, 2705). Tablets, with sweetish taste, v. sol. water. Dextrorotatory. Has no action on Fehling's solution until after boiling with mineral acids, by which it is converted into galactose and an isomeride (? glucose).  $HNO_3$  forms mucic acid, galactose, glucose, and cane-sugar. Gives a red colour on heating with resorcin and  $HClAq$ . Gives no pp. with lead acetate until  $NH_4Aq$  is added.

**STANNATES**, and salts related thereto; v. under Tin.

**STAPHISAGRINE** v. DELPHININE.

**STARCH.** *Amylum*.  $nC_{12}H_{20}O_{10}$ . The value of  $n$  has not been definitely settled; it is undoubtedly high. Brown and Morris (C. J. 55, 462), employing Raoult's method for determining molecular weights, show  $n$  for soluble starch (see below) = 100, i.e. molecular weight = 32,400. The molecular weight of starch cannot be less than this. From O'Sullivan's work (C. J. 35, 783) it would seem that  $n$  is not less than 36. Pfeifer a. Tollens (B. C. 1882, 775; A. 210, 295), from the composition of some sodium and potassium compounds prepared from starch, arrive at the value  $n = 2$ ; the substances are probably compounds, not of starch, but of some decomposition products thereof. Sachsse (C. C. [3] 8, 732) and Nägeli (A. 173, 218) proposed  $60C_{12}H_{20}O_{10} + H_2O$  as the formula. Other observers (Mylus, B. 20, 694; Salomon, J. pr. [2] 28, 82) have suggested different formulae, but the evidence is not satisfactory; we may take it, however, that the molecule of starch is not less than  $n = 100$ .

**Occurrence.**—Starch is present at some time or the other in all green plants. It is said to be found in almost all parts of the plant, but it is specially stored up in seeds, the pith of stems, in bulbs, tubers, rhizomes, and roots—generally those parts of the plant which serve as a store for reserve material. It is, however, a question whether the granules recognised as starch in leaves, sap, &c., outside the reserve organs, are chemically identical with the starch of these organs. The evidence, one way or the other, is unsatisfactory. Starch is not known to be an animal product. It is present in some fungi (Bourquelot, J. Ph. [5] 24, 197).

**Formation.**—Starch has not been prepared artificially. It is produced in the chlorophyll cells of plants, light, carbon dioxide, and water being necessary; oxygen is eliminated at the same time. No doubt, intermediate products—amylan-like bodies, sugars, &c.—are at first produced, but the granules are the first visible products of the assimilation found in the leaves. The starch thus formed is transferred to the reserve organs as such, or, more probably, as some sugar or other transformation product or products, as leaves are known to contain transforming agents (Baranetzky, *Die stärkeumbildenden Fermente in den Pflanzen*, Leipzig, 1878; Brasse, C. R. 99, 878).

**Preparation.**—Starch of commerce is prepared from various sources—viz., amongst others, wheat, rice, maize, potatoes, *Maranta indica* (American starch), *Maranta arundinacea* (arrow-root), the roots of *Jatropha Manihot* or *Manihot utilisima* (tapioca), the stems of several

species of *Sagus* or *Oycas* (sago). For manufacturing methods see THORPE'S DICTIONARY, art. 'Starch.' In the laboratory, starch can be prepared from any starch-containing material as follows:—

*From materials that can be ground, such as the cereals, &c., wheat, barley, maize, rice, &c.* The material is ground in a coffee-mill, and the meal steeped in a 0.6 to 1 p.c. sol.  $KHO$  or  $NaHO$ . After standing 24–36 hours the coarser portions are separated by straining, with rubbing, and a slight flow of water through a wire sieve of about 20 wires to the inch. The strained milky liquid is allowed to stand for a short time, when a layer of crude starch settles at the bottom of the vessel. The liquid, with the matter in suspension, is transferred to another vessel, and again allowed to stand, when a second deposit of crude starch takes place. The process may be repeated a third and a fourth time. The whole of the suspended matter is thus allowed to settle, when the fairly clear supernatant liquid is decanted off and rejected. The deposit is then rubbed through a fine hair sieve, with a slight flow of water, and allowed to deposit a layer of starch as before. This is repeated as long as a starch layer separates. The whole of the starch layers are then collected, again suspended in water, and allowed to settle. At times a layer contaminated with much brown matter falls out first; from this the supernatant liquid with the starch in suspension is decanted off and allowed to stand, when a fairly pure deposit of starch is obtained. Further crops can be got from the residue, but it is difficult to free them from fibre, &c.

*From materials that cannot be ground, such as potatoes, bulbs, rhizomes, other roots, and pith.* The well-washed material is rubbed down with a grater into water, to which afterwards the alkali is added. The first deposit in these cases contains, as a rule, earthy matter, but it is easily separated by allowing it to settle, which it does in a short time, and then decanting off the starchy liquid. Two or three depositions and strainings through a fine hair sieve give a clean starch.

In dealing with the cereals the starch can be also separated by what is known as the acid process. The meal is steeped in water and kept at a temperature of from  $25^\circ$  to  $27^\circ$  until acid is developed. On then stirring up with water the light flocculent cell walls and undissolved albuminoids separate and allow the starch to deposit on standing. By repeated suspensions, stirrings, and depositions, clean crops of starch are obtained.

These products, like the starches of commerce, are not pure, but, as a rule, contain ash, oil or fat, albuminoids, &c. Some of them are slightly alkaline, some acid, from the condition of the water used in the last washing. Purification is effected by treatment with dilute  $KHO$  solution (0.5 p.c.), then dilute  $HCl$  (up to 1 p.c.), then with strong alcohol, and finally with water. They then can be dried by exposure to the air on layers of filter-paper.

**Structure.**—The starch thus obtained varies much in appearance, from the glistening silky white of potato starch to the dead chalky white of rice or maize starch. It consists of microscopic granules, varying in size from about 0.2

mm. to 0.002 mm. The same plant always yields granules of specifically the same size and shape, with as little variation as the size and shape of the leaf, hence, from the microscopic appearance of the granules, it is always possible to tell the source of a sample of starch. If it is wished to determine the source of any sample of starch, the following classification of the starches will be of some use. If, under the microscope, the granules are

(a) large, rounded, and more or less marked with rings: the starch may be potato, tapioca, sago, &c.

(b) rounded, very slightly ring-marked: barley, rye, wheat, &c.

(c) reniform: beans, peas, &c.

(d) intermediate in size, rounded, and irregular: crocus, tulip, and other bulbs.

(e) irregular in figure, bounded by surfaces more or less plain: maize, oats, rice, &c.

(f) small granules, rounded or irregular: fern, chestnut, parsnip, &c.

It will be observed that some of these are round, oval, or reniform, while others are irregular figures bounded by surfaces more or less plain. The microscopic appearance does not always give the true form of the granule, but a form which is the result of the pressure of the cover glass; for example, the well-marked star with central spot in rye starch and the split and striated appearance of maize starch are produced by the pressure of the cover glass on the granules. The granules of some starches are marked with well-defined more or less concentric rings, well shown in potato starch; in others there are no markings, the granules appearing as a clear, transparent cell. It is not absolutely agreed upon whether the starch granule consist of a single body or is made up of two or more. Some hold that the properly purified granule is a single substance, the coating or layers of which differ from the contents simply in containing less water and being thus more dense. According to Nägeli (*Die Stärkekörner*) and others, the dense portions consist of starch cellulose, while the less dense, transparent plasma is *granulose*. The stratified structure is the result of the mode of growth of the starch granule, the additions being made by intussusception, i.e. from within outwards. It is said that when the granule is ruptured the granulose dissolves in cold water, leaving the starch cellulose; the former gives the well-known blue reaction of starch with iodine, while the latter is only coloured yellowish (Jessen, *P.* 106, 497; *J. pr.* 105, 65; Brown a. Heron, *C. J.* 35, 610; Brukner, *M.* 4, 889). On heating the insoluble portion with water it also gives the characteristic blue reaction with iodine. Granulose may be separated from starch cellulose (a) by digesting the granules for several days with a saturated solution of NaCl containing 1 p.c. HCl—the cellulose remains undissolved (F. Schulze, *Henneberg's Jour. Landwirtschaft.*, new ser., 7, 214); (b) by digesting starch with saliva at 45°–55°, this dissolves the granulose (Nägeli, *Die Stärkekörner*, 110; (c) by the action of certain schizomycetes, which decompose the granulose of starch-paste and leave the cellulose untouched (Fitz, *B.* 10, 282); and (d) by the action of malt-extract on starch paste in the cold, the cellulose is left undissolved.

A. Mayer (*C. C.* 1887, 6; *Bot. Zeit.* 1886, 698) considers that the starch granule is a homogeneous substance, and that the terms 'granulose' and 'starch cellulose' must be abandoned, for he points out that the delicate transparent skeletons left when the gelatinised granules are acted on by saliva, dilute acids, &c., are produced by the action of the reagent on the starch, and are identical with amyloextrin. I am inclined to the view that starch granulose differs from starch cellulose in being less dense in consequence of containing less water of hydration. Starch granules act on polarised light, and when examined with the microscope between two Nicols, produce very pretty effects; v. Bailey (*P. M.* [5] 2, 123).

*Properties.*—Air-dried starch sometimes contains over 20 p.c. H<sub>2</sub>O; this it loses, slowly towards the end, in a vacuum over sulphuric acid; by gradually raising the temperature to 100°, under these conditions, it soon becomes absolutely free from H<sub>2</sub>O. The specific gravity of air-dried starch varies very considerably, the variation being due in the main to the quantity of moisture. Dry starches, however, would appear not to be absolutely alike in specific gravity; that of anhydrous potato starch is 1.650, whilst anhydrous arrowroot starch is 1.5648 (Flückiger, *Fr.* 5, 305; Saare, *J.* 1884, 1654). Dry starch takes up water, with the evolution of much heat. It does not dissolve in H<sub>2</sub>O, and has neither taste nor smell.

(a) *Action of heat.* Dry starch is not coloured at 100°, and, indeed, the temperature can be increased considerably beyond that point without being changed. Starch containing water is, however, coloured by a moderately low temperature, and if the heat be increased to 160° a soluble product is obtained which is known as dextrin or British gum. It is a mixture of undescribed composition. The action of heat on dry starch has not yet been accurately recorded. When the heat is increased beyond 160°, and destructive distillation begins, carbon dioxide, gaseous hydrocarbons, water, acetic acid, and an empyreumatic oil are evolved, and finally a carbonaceous porous cinder is left.

(b) *Action of water.* As long as the granules are uninjured, starch is insoluble in cold water; when, however, the water is heated, the granules swell up, and a gelatinous, more or less transparent mass, known as starch-paste, is produced. This varies in transparency with the starch employed, as does the temperature at which the gelatinisation takes place. E. Lippmann (*C. C.* 1861, 859; *J. pr.* 83, 51) gives the following table on this point:

Source	Swelling-up temp.	Commencement of gelatinisation	Perfect gelatinisation
Rye	45°	50°	55°
Maize	50°	55°	62.5°
Barley	37.5°	57.5°	62.5°
Potato	46°	59°	62.5°
Rice	54°	59°	68°
Wheat	60°	65°	67.5°

If the paste is sufficiently dilute it can be filtered, but it is doubtful if the filtrate is a true solution (Piton a. Linder, *C. J.* 61, 156). The consistency or stiffness of starch-pastes, containing the same amount of dry starch, seems to

vary with the variety of starch employed, and, indeed, with the method of preparation, even with the same starch; but I feel inclined to think that if closer attention were given to the amount of dry starch and its purity much of this apparent difference would disappear. On the relative stiffness of flour or starch pastes, and the mode of estimating it, see Thomson (*S. C. I.* 1886, 143). If the paste be heated under pressure to temperatures above the boiling-point, maltose and dextrin are said to be produced, but the change has not been accurately studied.

(c) *Action of glycerol.* Starch heated with glycerol to 190° is dissolved; alcohol ppts. soluble starch from the solution. If the heating be continued at 200°, dextrins are formed (Zulkowski, *B.* 13, 1905; 23, 3295; *C. C.* 1888, 1060).

(d) *Action of acids.* Moderately strong HCl in the cold converts starch, in a few days, without changing materially its microscopic appearance, into a modification perfectly soluble in water. This body is identical with soluble starch prepared by the limited action of malt extract on starch paste (C. Lintner, *J. pr.* 34, 378; Brown a. Morris, *C. J.* 55, 450). Prolonged action of 12 p.c. HCl in the cold produces amylo-dextrin (Nägeli, *Beiträge z. Kenntniss d. Stärkegruppe*; Brown a. Morris, *C. J.* 55, 450). Boiling dilute acids convert starch, first into soluble starch, then into dextrin and maltose, intermediate products, *amyloins*, are said to be formed (Brown, Morris a. Moritz, *E. P. No.* 1809 of 1889), and finally dextrose. The complete conversion takes place the more quickly and perfectly the higher the temperature and the longer the period of the reaction (Allihn, *J. pr.* 22, 46; *D. P. J.* 250, 534). This is only accomplished by employing diluted acid. Carbonic acid, oxalic acid, &c., act like HCl and H<sub>2</sub>SO<sub>4</sub>, but less energetically. For the manufacture of dextrose (glucose) from starch, *vide* THOMAS'S DICTIONARY. The action of acids has been studied chiefly by Kirchhoff, Guérin-Varry, Payen (see *Gm. K.*), Musculus (*A. Ch.* [3] 60, 203; *J. pr.* [2] 28, 496; *Bl.* 30, 4; O'Sullivan (*C. J.* 25, 581); Musculus a. Gruber (*C. R.* 86, 1459; *Bl.* [2] 30, 54); Bondonneau (*C. R.* 81, 972); Salomon (*J. pr.* [2] 25, 348; 26, 342; 28, 82 a. 122); Sachsse (*C. C.* [3] 8, 732); Schulze (*J. pr.* [2] 28, 311); Sostegne (*G.* 15, 376); Seyberlich a. Trampedach (*C. C.* 1887, 376); Nägeli (*Stärkegruppe*, Leipzig, 1874, 83, 99). As a summary of this work it may be stated that dextrose is the final product, but that acids act on this, to some extent yielding products still imperfectly investigated; that intermediate substances, dextrin and maltose and compounds thereof, are first produced; that the rapidity of the change varies with the strength of the acid, with the temperature, and with the pressure at which the change is effected, the most complete and perfect production of dextrose resulting when the conversion is hastened under pressure in presence of a small percentage of acid, 1½ to 2 p.c. or less, and the proportion of dry starch to dilute acid does not exceed 1 to 3. *Gallatin* (*C. Schmitt a. Cobenzl*, *B.* 17, 1000; Rosenbek, *B.* 17, 2456), a gummy body, is found in commercial glucose. This is identical with isomaltose obtained by Fischer (*B.* 23, 3687) by the action of strong HCl on dextrose (Scheibler a. Mittelmeier, *B.* 24, 301).

*Action of diastase (malt extract).* Diastase does not act on ungelatinised starch in the cold (O'Sullivan, *C. J.* 30, 133; Brown a. Heron, *C. J.* 35, 596), but Kjeldahl has shown that this is not true of all starches. This is probably due to some condition of the starch connected with the state of ripeness of the material whence it was obtained. The action, and the products thereof, of diastase on starch paste has been the subject of much study, but as yet only the broad facts are agreed upon. When starch paste is heated to 60° or thereabouts, and a little prepared diastase solution or cold water extract of malt added, the pastiness begins immediately to disappear, the solution rapidly loses the power of giving a blue colour with iodine, and acquires, for a short time, the property of giving with that reagent a deep reddish-brown colour. This, too, it rapidly loses if the diastase is in sufficient quantity. The solution is then perfectly clear when some starches are employed, with others there is more or less flocculent suspended matter in a clear solution. In the cold this dissolution takes place slowly. So far the reaction can be followed with little trouble, but when it comes to a question of the products of the action, the subject becomes more difficult. Musculus (*A. Ch.* [3] 55, 203) states that when diastase dissolves starch paste at 70°-75°, the products consist of 1 mol. sugar and 2 mols. dextrin, and that no further action takes place. Payen (*A. Ch.* [4] 4, 286) asserts that more than 50 p.c. of the solid matter dissolved by the reaction is sugar, and says (*A. Ch.* [4] 7, 382) that four samples taken from an operation in the space of 1½ hours contained 17.9, 20.9, 25.8, and 26.03 p.c. sugar on the total solids dissolved. Schwarzer (*J. pr.* [2] 1, 212) agrees with Musculus in finding equivalent quantities of dextrin and sugar in solution, but differs from him in supposing that dextrin is formed first, then sugar, and that the action ceases when definite equivalent proportions are produced. He says less sugar is produced at 65° than at lower temperatures; above 65°-70° the proportion of sugar to dextrin is as 1 eq.: 3 eqs.; below 60°, when the principal phase of the reaction is finished, the dextrin and sugar are in the proportion of 1 to 1. The change was considered complete when the solution no longer gave a colour with iodine. These investigators took the sugar as dextrose and estimated the dextrin by difference. O'Sullivan (*C. J.* 25, 581; 30, 137) showed that the sugar produced was not dextrose but maltose, and that the method of estimating the dextrin was wrong. He also demonstrated that dextrin and maltose were the invariable products of the transformation, and that by continuing the action the whole of the dextrin could be converted into maltose. It was, however, indicated in this work that another body—from which it was impossible to eliminate the cupric reducing power, and which seemed to be a mixture of maltose and dextrin—was amongst the products. Although this work laid the foundation of all that has since been done in the transformation products of starch, it received for a time no attention from the Continental chemists. Musculus (*Bl.* 22, 32) states that the saccharification of starch paste with diastase ceases when half the matter in solution is sugar. He attri-

butes his original impression that only one-third was converted into sugar to the varying structure of the starch granules, the coating of one variety offering a greater resistance to the action of the diastase than that of another. He still holds that the action is a molecular splitting-up of the starch molecule, attended with hydration, into dextrin and sugar. Bondonneau (*C. R.* 81, 1212) concludes that the action is not a splitting-up, but that the starch molecule must pass through four isomeric modifications, viz., amylogen  $[\alpha]_D = +216^\circ$ ,  $\alpha$ -dextrin =  $+186^\circ$ ,  $\beta$ -dextrin =  $+176^\circ$ , and  $\gamma$ -dextrin =  $+164^\circ$ , before it arrives at the end-product, *glucose*. These bodies increase in cupric-reducing power as they descend to the final product. Petit (*Bl.* 24, 519) mentions, as a constituent of the transformation products, a sugar soluble in alcohol, fermentable, and without action on alkaline copper solution. This is, undoubtedly, to be traced to the fact that maltose does not reduce as much copper oxide as dextrose. O'Sullivan (*C. J.* 30, 125; 35, 770) showed conclusively when working under clearly-defined conditions that maltose and dextrin were the only products of the action, although, as stated, he pointed out the presence of a body which gave a reduction with copper oxide equal to 9-10 p.c. dextrose. The opticity of this body ( $[\alpha]_D = +204^\circ$ - $206^\circ$ ) was such as to indicate a mixture of 12.3-15.3 p.c. maltose from the reduction, and the remainder dextrin. He concluded that if the amount of reduction of the products be calculated as maltose, and the opticity due to this be subtracted from the total opticity observed for them, the remainder will agree with the activity of an amount of dextrin obtained by subtracting the determined maltose from the total products. He further showed that: (a) malt extract begins to dissolve starch at the temperature of gelatinisation, or a few degrees lower; (b) perfectly gelatinised starch is almost completely dissolved in the cold ( $10^\circ$ - $20^\circ$ ); (c) at  $63^\circ$  the action takes place according to the equation

(d) at  $64^\circ$ - $70^\circ$  to

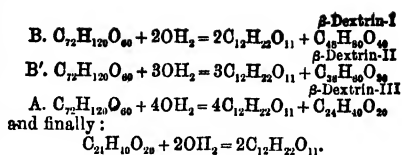

(e) at  $70^\circ$ - $71^\circ$  (*C. J.* 1879) to

(f) and  $71^\circ$ - $75^\circ$  to

(g) and he stated that although the proportions of maltose and dextrin indicated by these equations are easily obtainable when the strict conditions are adhered to, it was only necessary to vary the proportions of malt extract and starch, and time and temperature, to obtain with ease products containing from 16 to 92 p.c. maltose. It is further pointed out that the final product, maltose, was very slowly converted into dextrose by some samples, at least, of *malt extract*. O'Sullivan (*C. J.* 35, 770) showed that soluble starch was the first product of the action, and that the changes afterwards brought about may be expressed:

From the action of malt extract on these products he concluded that it is possible that only one  $\beta$ -dextrin exists. The theory of splitting up and breaking down of the starch molecules, as represented by the equations, does not account for all the facts eliminated. A theory which arranges all the molecules in solution in groups, dependent one on the other—and capable, therefore, of undergoing a simultaneous change, or of being moved at the same time—and the re-arrangement of these groups attendant upon the hydration of a definite proportion of the molecules in each of them, is more in accord with the eliminated facts. Märker (*L. V.* 22, 69) states that at  $60^\circ$  four molecules starch yield three of maltose and one of dextrin, at  $65^\circ$  there is less maltose, and at a higher temperature two molecules starch yield one of maltose and one of dextrin. Musculus and Gruber (*Bl.* 30, 54) look upon starch as a polysaccharide containing at least five times the group  $C_6H_{10}O_5$ . When this is acted upon by diastase, or dilute acids, it is broken down with hydration into maltose and a dextrin containing a  $C_{12}H_{22}O_{11}$  group less than starch; that this dextrin is broken down in the same way, maltose and a dextrin containing a  $C_{12}H_{22}O_{11}$  group less than the first one, and so on through the series by successive stages, until finally the solution contains only maltose. They point to the existence of three dextrins giving no reaction with iodine, and call them  $\alpha$ ,  $\beta$ , and  $\gamma$  achroo-dextrins. From the optical activity and K they attribute to these bodies, they do not agree with O'Sullivan; these factors do not agree with those of a mixture of maltose and dextrin. Brown and Heron (*C. J.* 35, 596) have eliminated out of the possible varying proportions of maltose and dextrin indicated by O'Sullivan eleven distinct transformations: viz. soluble starch, erythro-dextrin  $\alpha$  and  $\beta$ , achroo-dextrins  $\alpha$  to  $\eta$ , and maltose. They agree with O'Sullivan that the dextrins are without action on alkaline copper solution, and that the dextrins and maltose are the only products of the reaction. They do not mention the body from which O'Sullivan could not eliminate the reducing power, and they did not observe dextrose amongst the final products with malt extract. They agree with him that the higher the temperature at which the transformation takes place the less maltose is found amongst the products. They represent the normal reaction taking place between  $10^\circ$  and  $60^\circ$  by the equation

They consider the starch molecule to be at least  $10C_{12}H_{20}O_{10}$ , and that the hydrolysis of it begins by the formation of maltose and erythro-dextrin  $\alpha$ , containing  $9C_{12}H_{20}O_{10}$ ; that this, in its turn, yields maltose and erythro-dextrin  $\beta$ ,  $8C_{12}H_{20}O_{10}$ , and so on to the end-product, maltose. They thus agree with Musculus and Gruber as to the

character of the action, but disagree with them as to its quantitative nature.

Herzfeld (*B.* 12, 2120; 18, 3469) agrees with O'Sullivan and others that erythro- and achroo- dextrins are without reducing power on copper solution, but he points to the presence of a substance amongst the transformation products which seems to hold a position between dextrin and maltose; he names it *malto-dextrin*.  $K = \text{about } \frac{1}{2}$  maltose,  $[\alpha]_D = +171.6^\circ$ ; thus  $K$  corresponds to 33.3 p.c. maltose. A mixture consisting of one-third maltose and two-thirds dextrin would have an opticity  $[\alpha]_D = +199^\circ$ ; hence this contradicts the statement of O'Sullivan, confirmed by Brown and Heron, that, taking the reducing power as maltose, the opticity of the remainder of the transformation products corresponds to dextrin. Herzfeld considers that Bondonneau's  $\gamma$ -dextrin is malto-dextrin.

Brown a. Morris (*C. J.* 47, 527) confirm the presence of malto-dextrin, but they show that Herzfeld was dealing with an impure body, and that when its true  $K$  and  $[\alpha]_D$ , viz.  $K = 21.1$  and  $[\alpha]_D = +193.1^\circ$ , are examined it is found that they correspond with a mixture of maltose and dextrin. It is completely converted into maltose by malt extract at  $50^\circ$  to  $60^\circ$ . They do not agree with Herzfeld that it is a hydration product of dextrin, but hold that it is produced from starch and the polymeric dextrins by the fixation of a molecule of water upon the ternary group  $(C_{12}H_{20}O_{10})_n$ , thus  $\left\{ \begin{matrix} C_{12}H_{20}O_{11} \\ (C_{12}H_{20}O_{10})_n \end{matrix} \right.$ . They have discarded the series of equations, and consider that equilibrium is attained when a condition of things represented by the equation

is arrived at. This is always the result when the change takes place at  $50^\circ$  to  $60^\circ$ , or when a higher transformation-product is degraded at that temperature. This degradation is due to the hydrolysis of the more complex polymeric dextrins and malto-dextrin. Bourquelot (*C. R.* 104, 516) looks upon the action of diastase on starch as a successive fixation of a water molecule with the production of maltose and a lower dextrin until the reduction of the degraded products is  $K = 51.52$  (about 82.5 p.c. maltose), but he does not describe his dextrin or dextrins, and he concludes, as has already been clearly proved, that heat alters, not alone the quantity of diastase, but the quality.

Brown and Morris (*C. J.* 55, 462), from determination of the molecular weights of some of the transformation products, conclude, as suggested by O'Sullivan in 1879, that the dextrins are metameric, and not polymeric, as they hitherto considered them. They therefore abandon their former theory of the hydrolysis of starch by diastase, and, as far as I can see, come to a broad agreement with the theory enunciated by O'Sullivan. They mention another product, amylo-dextrin,  $[\alpha]_D = +206^\circ$ ,  $K = 9.0$ . Like malto-dextrin, it appears to be a compound of maltose and dextrin,  $\left\{ \begin{matrix} C_{12}H_{20}O_{11} \\ (C_{12}H_{20}O_{10})_n \end{matrix} \right.$ . Its opticity and  $K$  agree with the body described by O'Sullivan in 1872, and mentioned above.

A new phase has been given to the trans-

formation by C. J. Lintner (*Zeit. ang. Ch.* 1892, 263). He says he has isolated a body, which he calls *isomaltose*, from amongst the products. It is less fermentable and less soluble in alcohol than maltose, with  $[\alpha]_D = +189$  and  $K = 52$ , the opticity being nearly that of maltose and the reducing power about 84 p.c. thereof. Diastase converts it into maltose completely.

Since the publication of the above Morris a. Wells (*Transactions of the Institute of Brewing*, 5, 133), and Moritz (*ibid.* 4, 141) point to the presence of a whole series of amyloins or malto-dextrins amongst what they call restricted starch-conversions, and they assert that isomaltose is a low amyloin—i.e. one in which the maltose constituent largely predominates. These amyloins begin with a high proportion of the dextrin residue, and end with a high proportion of maltose. Their optical activity and reducing power are such as would be yielded by mixtures of maltose and dextrin.

Schiffner (*In. Dissertation*, Basel) denies *in toto* the existence of the amyloins, and asserts that nothing is to be found amongst the products of the action of diastase on starch but achroo-dextrin, isomaltose, and maltose. His dextrin, however, is a reducing dextrin; even otherwise, the work will not bear criticism.

*Action of other enzymes. Ptyalin* (ptyalase). This enzyme of saliva liquefies starch paste (Nägeli, *Die Stärkekörner*, p. 118; Lefberg a. Georgieski, *Bl.* [2] 25, 393; Dobroslavine, *Bl.* [2] 26, 452; Maercker, *L. V.* 22, 69; Watson, *C. J.* 1879, 539; Musculus a. DeMering, *Bl.* [2] 31, 105; Lea, *J. Physiol.* 11, 226). The products are maltose, a reducing, unfermentable dextrin, and a little dextrose. Ungelatinised starch is not acted upon by ptyalase; at a temperature slightly below the gelatinising point the starch is dissolved, and the action is most rapid when the ferment acts at  $60^\circ$  on previously-boiled starch paste (Bourquelot, *C. R.* 104, 71 a. 177).

Enzymes capable of dissolving starch have been observed in the pancreatic juice (Brown a. Heron, *Pr.* 1880, 394), in the small intestine (Hoppe-Seyler, *Phys. Ch.* 275; Brown a. Heron, *l.c.*), in the liver (Wittich, *Pf.* 7, 28; Bernard, *C. R.* 85, 519; Abele, *Th.* J. 6, 271), and in many other animal tissues (Ellenberger a. Hofmeister, *Th. J.* 12, 501; Paschutin, *Th. J.* 1, 304). The stomach, pancreas, and peritoneal lymph of fishes contain an enzyme capable of dissolving starch (Richet, *Th. J.* 14, 859; Kruckenberg, *Unter. Phys. Inst. Heidelberg*, 1, 2). Blood contains a diastatic enzyme, for starch injected into the blood yielded maltose and dextrin (Bünnerman, *Pf.* 20, 201; Ploz a. Tiegel, *Pf.* 6, 249).

Starch-dissolving enzymes exist in the leaves and other parts of most plants (Baranetzky, *Die stärkebildenden Fermente in den Pflanzen*, Leipzig, 1878; Vines, *Ann. Bot.* 1891, 409).

Certain organisms, bacteria, moulds, &c., are capable of secreting an enzyme or enzymes having the power of dissolving starch. The nature of the dissolution products has, as yet, been very imperfectly studied; we have simply the general statement that they are sugar or sugars and dextrin (Wortman, *Z. P. C.* 6, 287; Fitz, *B.* 10, 282; Marcona, *C. R.* 95, 345 a. 856; Gayon a. Dubourg, *C. R.* 103, 885;

Atkinson, *Pr.* 82, 299; Takamine, *E. P.* 5700 a. 17874, 1891). *Bacillus amylobacter* yields dextrin and a small quantity of a crystalline body (Villiers, *C. R.* 112, 435 a. 113, 144 a. 536). Under the influence of *Bacillus suaveolens*, dextrin, glucose, alcohol, aldehyde, formic, acetic, and butyric acids are produced. Amylic alcohol is the result of the action of *Bacillus amylozymicus*, no doubt intermediate bodies; dextrin and sugar are at first produced. Atkinson states that the moulds grown on steamed rice in the manufacture of saké, in Japan, secrete an enzyme, which first converts starch into dextrin and maltose, and further acts on the maltose and dextrin, with the production of dextrose.

Some gums of the arabin group contain a starch-dissolving enzyme (O'Sullivan, *C. J.* 1891, 1061).

Maize, malted and raw, and other grains contain an enzyme capable of dissolving starch and yielding as a final product dextrose (Cuisinier, *C. C.* 1886, 614). Its action on starch is not very vigorous, but it acts more rapidly on dextrin and converts maltose very rapidly into dextrose (Geduld, *Wochenschrift f. Brauerei*, 8, 620; Lintner, *Zeit. f. ges. Brau.* 1892, 123). It would be interesting to determine in what respect this enzyme differs from that of the moulds, and to establish their separate existence.

**Action of the halogens.** Chlorine does not stain starch. Bromine colours it yellow. Iodine gives with it an intense blue. This reaction is a distinctive test for starch. The colour is destroyed by heating, but returns on cooling; but if the solution be boiled for some time, the colour does not reappear. The blue colour is also discharged by arsenious and sulphurous acids, by alkalis and carbonates thereof, and, indeed, alcohol can remove the iodine. A solution of iodine in strong alcohol does not colour dry starch. Some observers consider that the production of this blue colour is not due to a definite chemical combination of iodine with starch (Vogel, *N. Rep. Pharm.* 22, 349; 25, 565; Pellet, *M.* [3] 7, 988; Tomlinson, *P. M.* [5] 20, 168; Duclaux, *A. Ch.* [4] 25, 264), while others attribute a definite formula to the combination. According to Bondonneau (*C. R.* 85, 671), it is  $(C_6H_{10}O_5)_nI$ ; Mylius (*B.* 20, 688) considers it to contain HI, and gives the formula  $(C_6H_{10}O_5)_nHI$  as probable. He finds that the HI can be displaced by metallic iodides. Stocks (*C. N.* 56, 212; 67, 183) and Seyfert (*Zeit. ang. Ch.* 1, 15) contradict this. Rouvier (*C. R.* 114, 128 a. 1866) attributes the formula  $(C_6H_{10}O_5)_nI$  to the compound. Starch is oxidised by chlorine and by bromine to gluconic acid (Habermann, *A.* 172, 11; Herzfeld, *A.* 220, 364).

**Action of alkalis.** Weak solutions of the alkalis do not act on starch in the cold, but solutions containing over 8 p.c. real alkali cause the granules to swell up with the formation of a thick transparent paste, and, finally, a clear solution, a compound of starch with the alkali being formed (Schmidt, *A.* 51, 31; Ventzke, *J. pr.* 25, 65) which, according to the latter, is optically inactive, but this, no doubt, is incorrect, for Béchamp (*C. R.* 39, 663) gives the opticity  $[\alpha]_D = +211^\circ$  for the starch dissolved, and Thomsen (*B.* 18, 2168) shows that the ac-

tivity of dilute soda solutions is  $[\alpha]_D = +168$ . On neutralisation this becomes much higher, corresponding, in fact, with Béchamp's number. The product does not reduce alkaline copper solution (Brown a. Heron, *C. J.* 85, 617). The potassium compound is obtained by ppg. the solution in dilute KHO with alcohol, pressing the pp., dissolving in  $H_2O$ , and re-ppg. with alcohol. This process repeated three or four times is said to yield a pure compound of the composition  $C_{22}H_{38}O_{20}K$  (Pfeiffer a. Tollens, *A.* 210, 288). A sodium compound  $C_{21}H_{36}O_{20}Na$  has been obtained in the same way (Reichardt, *Z.* 1870, 404). These formulæ are, however, very improbable. Alcoholic soda does not act on starch (Dragendorf, *J. f. Landwirthschaft*, 7, 206).

Starch heated with ammonia yields brown, amorphous, nitrogenous bodies (Thénard, *C. R.* 52, 444).

Fused with KHO, starch, like other carbohydrates, yields oxalic acid, acetic acid, and other products.

**Action of alkaline earths.** Barium, strontium, and calcium compounds similar to the sodium and potassium bodies have also been prepared. When solutions of soluble starch are ppd. with solutions of lime in sugar syrup, pps. are produced which are not very definite in composition, the percentage of lime showing a variation between  $C_6H_{10}O_5CaO$  and  $(C_6H_{10}O_5)_2CaO$ . Similar baryta compounds have been examined. When a solution of soluble starch is saturated with strontia and alcohol added, a strontium compound is ppd. (Lintner, *Zeit. f. ang. Ch.* 1888, 232). On distilling starch with lime acetone, mesityl oxide, isophorone, and ketones are produced (Harvat, *C. C.* 1887, 38).

On digesting starch with acetic anhydride, a triacetate is said to be formed  $C_6H_7O_2(C_2H_3O_2)_3$  (Schützenberger a. Naudin, *Bl.* [2] 12, 110; *A. Ch.* [4] 21, 235; Michael, *Am.* 5, 359). This substance is amorphous; it is stained blue by iodine, and is decomposed by alkalis, with the reproduction of starch.

**Qualitative determination.** The presence of starch is indicated by the granular appearance under the microscope, and starch granules are distinguished from all others by being stained blue by iodine solution and yellow by bromine. If the plasma in which the granules are contained is alkaline, it must be rendered slightly acid, or sufficient iodine solution must be employed to destroy the alkalinity. A solution of iodine in potassium iodide is usually employed, but an alcoholic solution answers the purpose. When the test is applied for starch in solution, the solutions must be cold and slightly acid and the reagent must be added in small quantities at a time. It is sometimes necessary to test a solution for soluble starch in presence of  $\alpha$ -dextrin—i.e. the dextrin giving a reddish-brown colour with iodine. If this is in excess the reddish-brown colour covers the blue; ammonia added cautiously, drop by drop, discharges the reddish-brown, and if soluble starch be present the blue becomes definite and distinct. Care must be taken to avoid excess of ammonia (O'Sullivan). Small quantities of starch, which would otherwise not be observable, may be detected in the 'last runnings' of malt wort by adding a little

tannin and then alcohol to the solution. The starch is ppd. in this way, and on washing the pp. with water will yield the characteristic reaction with iodine (Burckhardt, *Chem. Zeit.* 1877, 1158). Starch, when moistened with an alcoholic solution of  $\alpha$ -naphthol and a few drops of warm concentrated sulphuric acid added, acquires a deep violet-red colour (Ihl, *Chem. Zeit.* 11, 19).

**Quantitative determination.** There are very few materials containing starch of which a sufficiently accurate average sample can be obtained to render a definite estimation of the starch therein of much value.

In some cases separation of the starch, by one of the methods given for its preparation, gives results of sufficient accuracy to satisfy the requirements.

In the case of potatoes, the percentage of starch is deduced from the specific gravity, a set of specially-constructed tables being used; but this method, on the face of it, cannot yield more than an approximation. The specific gravity of the washed potatoes is taken in the usual way, a balance constructed to meet the requirements of the case being employed. About 5 kilos. of the potatoes are weighed in a strong wire basket in air, and then in water; thence,

specific gravity =  $\frac{\text{weight in air}}{\text{weight in air} - \text{weight in water}}$ .  
According to the tables of Behrend, Märker, and Morgan, we have from

Sp. gr.	Per cent. of starch	Sp. gr.	Per cent. of starch
1.080	13.9	1.120	22.5
1.090	16.0	1.130	24.6
1.100	18.2	1.140	26.7
1.110	20.3		

In cases in which fair average samples of the material can be obtained, several methods have been proposed, all depending on the conversion of the starch, or the starch transformation products, into dextrose by digestion with dilute HCl or  $H_2SO_4$ , the dextrose being estimated with Fehling's solution, volumetrically or gravimetrically, and the starch calculated therefrom according to the equation  $C_6H_{10}O_5 + H_2O = C_6H_{12}O_6$  (v. Sachsse, *C. C.* [3] 8, 732; Märker, *Handb. der Spiritusfabrication*, 4. Aufl., Berlin, 1886, 93; Soxhlet, *Zeit. f. ges. Brau.* 1881, 177; Faulenbach, *Zeit. f. phys. Chem.* 7, 510; Zipperer, *Rep. An. Chem.* 6, 699). Dubrunfaut dissolved the starch by rubbing the material with concentrated HCl, diluting the solution with water to a certain volume, and determining the opticity. The starch was calculated from  $[a]_D = 192.4^\circ$ .

Effront (*Bl.* [2] 47, 5) dissolves the starch with malt extract, determines the optical activity of the solution, then heats it with ammonia, after which he treats it with sodium hypochlorite and with HCl, and again determines the opticity; but this method is open to many objections.

These methods are unsatisfactory, inasmuch as it is difficult, if not impossible, to completely convert starch or starch products into dextrose, there being a probable error at one time from over-conversion, at another from under-conversion; and, indeed, both may occur at the same time,

the amount of reduction of Fehling's solution taken as dextrose never being a correct measure of the starch transformed. Another objection to the method is due to the fact that dilute acids convert other substances besides starch into bodies capable of reducing copper oxide.

Girard (*C. R.* 104, 1629) titrates starch with iodine solution, 1 grm. of starch taking up 0.157 grms. iodine.

Asboth (*Chem. Zeit.* 11, 785) proposes to add an excess of baryta water to the gelatinised starch and then alcohol. The dried pp. contains 19.8 p.c. BaO, the remainder is starch. This method, too, cannot be of any use.

O'Sullivan (*C. J.* 45, 2) described a method by which starch in most materials can be estimated with accuracy. If a fair average sample of the material cannot be obtained by grinding and powdering alone, it is first dried in warm, dry air and then powdered. The following is the method as applied to the cereals, but it is also applicable to all materials when treated as just described.

Five grams, or thereabouts, accurately weighed—more if the material contains less than 40 p.c. starch—of the finely-ground material are introduced into a wide-necked flask of 100 to 120 c.c. capacity. To this sufficient alcohol of sp. gr. 0.82 is added to saturate it, and after a time 20 to 25 c.c. ether are introduced. The clear, ethereal solution is decanted off after standing for a few hours, and the residue again treated two or three times with ether. It is then extracted with alcohol, sp. gr. .90, at  $35^\circ$  to  $38^\circ$ , and treated with a large bulk of water, with which it is left in contact for at least 24 hours. If any sign of fermentation shows itself, a little salicylic acid solution may be used with the water. The residue, after being completely extracted with water, together with the filter, through which all the extracts should have been passed, is transferred to a beaker of about 100 c.c. capacity, and made up with water to about 40 to 45 c.c. This is heated to boiling for a few minutes in a water bath, care being taken, by continual stirring, to insure a homogeneous paste; then cooled to  $62^\circ$  to  $63^\circ$ , and 0.025 to 0.035 gram prepared diastase or its equivalent of malt extract added, the digestion being then continued at the temperature stated for a few hours. At the end of that time the contents of the beaker are boiled for a few minutes, thrown on to a filter, and the filtrate received in a 100 c.c. measuring flask. The residue is carefully washed with small quantities of boiling water at a time, and the filtrate made up at  $15.5^\circ$  to  $100^\circ$  c.c. A determination of the reducing power calculated as maltose, and of the remainder of the optical activity as dextrin, gives the data for calculating the quantity of starch. This holds good even though the amyloïn theory of the breaking down of starch be proved to be accurate.

**Example.**—5 grms. barley-flour treated as described, 0.03 grm. prepared diastase being employed, gave 100 c.c. solution of sp. gr. 1.01008 = 2.589 grms. solid matter. 9.178 grms. this sol. reduced 0.241 grm. CuO. Opt. act. in

<sup>1</sup> If cold-water malt extract be used, a portion of it must be heated for the same time and at the same temperature as the assay; then boiled, and the opticity and reducing power determined; these factors calculated on the quantity employed must be allowed for.

200 mm. tube = +21.1 divs. (Soleil-Ventake-Scheibler saccharimeter). Hence

$$0.241 + 0.7256 \text{ (K of maltose} = 62.5)$$

$$= 0.1748 \text{ grm. maltose;}$$

$$9.178 \text{ grms. : } 101.003 \text{ (the wt. of 100 c.c. sol.)}$$

$$:: 0.1748 : x;$$

$$x = \text{maltose in the 100 c.c. sol.} = 1.923;$$

$$\text{Opt. act. maltose } [\alpha]_D = +15.4^\circ \text{ and of dextrin } [\alpha]_D = +22.2^\circ.$$

Hence 1 grm. maltose in 100 c.c. sol. in 200 mm. tube = 8.52 divs. of instrument mentioned, and 1 grm. dextrin under like circumstances = 11.56 divs. Then  $1.923 \times 8.02 = 15.422$  divs. opt. activity of the maltose,  $21.1 - 15.422 = 5.678$  divs. opt. activity of the dextrin, and  $5.678 + 11.56 = 0.491$  grm. dextrin in the 100 c.c. sol. Dextrin is derived from starch without any increase of weight: 100 grms. starch yield 105.5 maltose; hence

$$1.055 : 1.923 :: 1 : x \text{ starch - maltose;}$$

$$x = 1.822 \text{ grms. starch.}$$

$$1.822 + 0.491 \text{ (as dextrin)} = 2.313 \text{ starch; in the 5 grms. taken} = 46.26 \text{ p.c.}$$

It is clearly shown in the paper quoted that if starch is not estimated in the way indicated no reliance can be placed on the results. It happens when dealing with some varieties of material that the aqueous extract contains *soluble starch* (blue colour with iodine). This cannot be looked upon as starch; it must be estimated in the solution as the soluble modification.

Soluble starch may be prepared (a) by triturating starch with sharp sand or powdered glass so as to disintegrate the granules and extracting with cold water; (b) by the limited action of malt-extract or of acid.

Delffs (P. 109, 648) prepared soluble starch by triturating starch with sand and water; the solution gave a dark-blue colouration with iodine. Flückiger (Z. 1861, 104) prepared a similar solution by acting on starch with a concentrated solution of calcium chloride and treating the resulting gummy mass with water, when, on filtration, a solution is obtained which exhibits all the characteristics of soluble starch. Musculus (Bl. [2] 22, 26; A. Ch. [5] 2, 385) does not consider this a true solution; he prepares the body by boiling starch with very dilute sulphuric acid, saturating the solution with chalk, and evaporating to a syrup. This deposits small granules which gradually increase in size, are soluble in hot water, and may be purified by precipitation with alcohol. It possesses no reducing power; its rotatory power is four times that of glucose. Bon-donneau (C. R. 80, 671) has prepared soluble starch by this method, but does not find it altogether soluble under all conditions. Soluble starch is undialysable. Fuming nitric acid converts it into a mononitro-derivative,  $C_6H_7(NO_3)O_5$ ; dilute nitric acid oxidises it to carbonic and oxalic acids; bromine and silver oxide to gluconic acid (Reichardt, B. 8, 1020; 7, 424).

Nägeli (Beiträge z. näheren Kenntniss der Stärkegruppe, Leipzig, 1874, p. 33, 99; A. Ch. 178, 218) gives the following method: 1 kilo. potato starch is allowed to stand 6-8 weeks with 6 litres hydrochloric acid, S.G. 1.06; this is then purified by solution in hot water; it crystallises in spherocrystals (Jaquelain, A. Ch. [2] 16, 178). According to Brown & Morris, this is

not soluble starch (v. above). Zulkowski (B. 18, 1895) prepares soluble starch by heating dry potato starch with glycerol at  $180^\circ - 190^\circ$  for half an hour. The solution is cooled, precipitated by alcohol, and the precipitate purified by solution in water and reprecipitation by alcohol.

Salomon (J. pr. [2] 28, 82) finds that soluble starch is the first product of the action of dilute acids on starch; it does not reduce Fehling's solution, and has an optical activity  $[\alpha]_D = -211.5^\circ$ . O'Sullivan (C. J. 1879, 772) prepares soluble starch by dissolving starch paste at  $73^\circ - 74^\circ$  with the least possible quantity of cold water extract of malt, boiling the solution as soon as it becomes clear, filtering, and concentrating. The soluble starch falls out on cooling as a white precipitate, which is purified by dissolving in hot water and allowing to cool when it separates out again. It has a reducing power,  $8.5 - 0.78$ , and an optical activity  $[\alpha]_D = 219.5 - 222.0$ , the reducing power being probably due to a small quantity of maltose; v. also *Action of acids on starch*, above. C. O'S.

**STEARIC ACID**  $C_{18}H_{36}O_2$ . Mol. w. 284.  $(69^\circ)$ .  $(232^\circ \text{ cor. at } 15 \text{ mm.})$  (Krafft, B. 17, 1629);  $(359^\circ - 383^\circ)$  (Carnelley a. Williams, B. 12, 1360). H.F. 126,000 (Von Rechenberg). S.G. (liquid)  $22.845$ ; (solid)  $2.101$ ;  $1.00$ . S.V.S.  $332.6$  (R. Schiff, A. 223, 264). S. (alcohol)  $2.5$  in the cold. S. (benzene)  $22$  at  $23^\circ$ . S. (CS<sub>2</sub>)  $30$  (Vogel, J. 1866, 892). Occurs as glyceryl stearate in very many fixed animal and vegetable fats and oils (Chevreul, A. Ch. 88, 225; [2] 2, 354; 23, 19; Braconnot, A. Ch. 93, 250; Redtenbacher, A. 35, 46; Bromeis, A. 35, 86; 37, 303; Stenhouse, A. 36, 57; Erdmann, J. pr. 25, 497; Francis, A. 42, 256; Gottlieb, A. 57, 35; Laurent a. Gerhardt, A. 72, 272; Hardwick, C. J. 2, 232; Crowder, P. M. [4] 4, 21; Berthelot, A. Ch. [3] 41, 216, 432; 47, 297; Pöbel, A. 91, 138; Heintz, A. 92, 295; Johnston, C. J. 29, 8).

**Formation.**—1. By saponification of cetyl-acetoacetic ether, obtained from cetyl iodide and sodium acetoacetic ether (Guthzeit, A. 206, 351). 2. By heating cetyl-malonic acid at  $150^\circ$ .—3. From ricinoleic acid by treatment with water, P, and I, followed by zinc and HClAq (Claus, B. 9, 1916).—4. By heating oleic acid with iodine (1 p.c.) for several hours at  $275^\circ$  and distilling the product in a current of superheated steam (De Wilde a. Reyckler, Bl. [3] 1, 295).

**Preparation.**—Suet or cacao fat is saponified by NaOH aq, the acids ppd. by  $H_2SO_4$  and crystallised from alcohol. An alcoholic solution of the impure stearic acid (4 pts.) saturated at  $0^\circ$  is heated to  $60^\circ$  and mixed with a boiling alcoholic solution of  $Mg(OAc)_2$  (1 pt.). The ppd. magnesium stearate is boiled with HClAq and the stearic acid recrystallised from alcohol (Heintz). Stearic acid can also be readily obtained from shea-butter which contains no other solid fatty acid (Buff a. Oudemans, J. pr. 89, 215).

**Properties.**—Pearly plates, insol. water, sol. alcohol and ether. Tasteless and inodorous. May be distilled *in vacuo* and, in small quantity, under atmospheric pressure, but in this case it is partly decomposed with formation of hydrocarbons, stearone, water,  $CO_2$ , acetic acid, and butyric acid. Fusion with  $P_2O_5$  forms  $C_{18}H_{34}O$   $(54^\circ - 60^\circ)$ . Nitric acid forms sebacic, glutaric,

succinic, and other acids. In and water at 140° form bromo- and dibromo-stearic acids (Oudemans, *J. pr.* 89, 193). Distillation *in vacuo* with NaOMe yields  $C_{17}H_{34}$  (Mai, *B.* 22, 2133).

**Salts.**— $KA'$ : Hygroscopic crystals. *S.* 4 in hot water. Partially decomposed by a large quantity of water into an insoluble acid salt and free potash.— $KHA'$ : Silvery scales (from alcohol). *S.* (alcohol) 36 in the cold; 27 at 78°. Boiling water converts it into a more acid salt.  $NaA'$ — $NaHA'$ : Insol. water.— $BaA'_2$ : minute laminae, insol. water.— $CaA'_2$ — $SrA'_2$ — $MgA'_2$ : minute laminae (from alcohol).— $CuA'_2$ : light-blue amorphous powder.— $PbA'_2$ : amorphous powder, insol. ether.— $Pb_2OA'_2$ — $AgA'$ : white pp.

**Methyl ether  $MeA'$ .** [38°]. Crystalline, insol. water (Hanhart, *C. R.* 47, 230).

**Ethyl ether  $EtA'$ .** [33°]. [224°]. Formed by heating the acid with alcohol at 200° (Lassaigne, *A.* 13, 168; Berthelot, *A.* 88, 312) by passing HCl into an alcoholic solution of stearic acid (Redtenbacher, *A.* 35, 51) and by heating stearin with a little NaOEt (Duffy, *C. J.* 5, 197; Bouis, *C. R.* 45, 35). Crystalline mass, partially decomposed by distillation. *V. sol.* alcohol.

**Ethylene ether  $C_2H_4A'$ .** [76°]. From  $AgA'$  and  $C_2H_4Br_2$  (Wurtz, *A. Ch.* [3] 55, 436).

**Isoamyl ether  $C_5H_{11}A'$ .** [25°].

**Octyl ether  $C_8H_{17}A'$ .** [45°].

**Cetyl ether  $C_{16}H_{33}A'$ .** [55°–60°]. Laminae (from ether) (Berthelot, *A. Ch.* [3] 56, 70).

**Glycerol ethers *v.* vol. ii. p. 622.** A mixture of stearic acid and glycerin saturated with HCl at 100° forms  $C_2H_5Cl(OH)(OC_{17}H_{33}O)$  [23°].

**Phenyl ether  $PhA'$ .** [52°]. [267° at 15 mm.] (Krafft a. Bürger, *B.* 17, 1380).

**p-Tolyl ether  $C_6H_4A'$ .** [54°]. [276° at 15 mm.].

**Chloride  $C_{17}H_{33}OCl$ .** [23°]. [215° at 15 mm.]. Crystalline mass.

**Amide  $C_{17}H_{33}ONH_2$ .** [109°]. Formed by distilling ammonium stearate at 230° under pressure; the yield being 50 p.c. (Hofmann, *B.* 15, 984; cf. Carlet, *B.* 1859, i. 76). Formed also by the action of  $NH_3$  on the ether or on the chloride. Converted by the action of Br and NaOHaq. into stearyl-heptadecyl-urea (Turpin, *B.* 21, 2486).

**Anilide  $C_{17}H_{33}ONHPh$ .** [94°]. Formed by distilling aniline over stearic acid at 230° (Fébal, *A.* 91, 152). White needles.

**Phenyl hydrazide  $C_{17}H_{33}CO.N_2HPh$ .** [107°]. Formed by heating stearic acid with phenyl-hydrazine. White unctuous plates (from alcohol), sl. sol. cold alcohol, benzene, and ether (Strache a. Irtzer, *M.* 14, 37).

**Nitrile  $C_{17}H_{33}CN$ .** [42°]. [275° at 100 mm.]. *S.G.*  $\frac{2}{3}$  815; 192–779. Formed by distilling stearamide with  $P_2O_5$  (Krafft a. Stauffer, *B.* 15, 516, 1730) or by heating cyanostearic acid at 250° (Hell a. Sadomsky, *B.* 24, 2770).

**References.**—Bromo-, Di- bromo- iodo-, Chloro-, Iodo-, Nitro-, and Oxy-stearic acid.

**Isostearic acid  $(C_8H_{17})_2CH.CO_2H$ .** [38–5°]. [278° at 101 mm.]. Formed from di-octyl-acetoacetic ether or di-octyl-malonic acid (Conrad a. Guthzeit, *A.* 204, 11, 165). Colourless leaflets (from alcohol).— $NaA'$ : needles (from alcohol).— $AgA'$ : thick white pp.

**Ethyl ether  $EtA'$ .** [275°–280° at 100 mm.].

**Vol. IV.**

**STEARIC ALDEHYDE  $C_{17}H_{34}O$ .** [64°]. [213° uncor. at 22 mm.]. Formed by distilling calcium stearate with calcium formate (Krafft, *B.* 13, 1417). Plates with bluish glitter, sl. sol. ether.

**STEARIN *v.* Stearyl derivative of GLYCERIN.**

**STEAROLIC ACID  $C_{17}H_{32}O_2$ .** Mol. w. 280. [48°]. [260°]. Formed by heating bromo-oleic acid or the dibromide of oleic acid with alcoholic potash at 100° (Overbeck, *J. pr.* 97, 159; *A.* 140, 49). Needles (from alcohol), insol. water. Br forms  $C_{17}H_{32}Br_2O_2$  and  $C_{17}H_{32}BrO_2$  [70°]. I and  $FeI_2$  in  $CS_2$  form  $C_{17}H_{32}I_2O_2$  [51°] (Liebermann a. Sachsse, *B.* 24, 4116). Potash-fusion yields myristic acid  $C_{14}H_{26}O_2$  and an acid  $C_{16}H_{30}O_2$  [21°] (Marasse, *Z.* [2] 5, 571; *B.* 2, 359). Alkaline  $KMnO_4$  oxidises it to suberic and stearoxylic acids (Hazura a. Grüssner, *M.* 9, 952).  $HNO_3$  yields azelaic, stearoxylic, pelargonic, and nitroso-pelargonic acids (Limpach, *A.* 190, 294). Phenylhydrazine at 140° gives  $C_{17}H_{31}CO.N_2HPh$  [82°] (Holt, *B.* 25, 2670).— $BaA'_2$ — $CaA'_2$  aq.— $AgA'$ .

**STEARONE  $(C_{17}H_{33})_2CO$ .** *Di-heptadecyl ketone.* [88°]. *S.G.* (liquid)  $\frac{2}{3}$  7979 (Krafft, *B.* 15, 1715). Formed by heating stearic acid (9.5 g.) with  $P_2O_5$  (5 g.) at 210° (Kipping, *C. J.* 57, 537; cf. Bussy, *A.* 9, 269; Redtenbacher, *A.* 35, 57; Varrentrapp, *A.* 35, 80; Rowney, *C. J.* 6, 97; Heintz, *P.* 94, 272; 96, 65). Got also by distilling the stearyl derivative of heptadecyl-urea with lime (Turpin, *B.* 21, 2486). Plates, sl. sol. hot alcohol. Br forms  $C_{17}H_{33}BrO$  [72°].

**Oxim  $(C_{17}H_{33})_2C:NOH$ .** [63°]. White powder, m. sol. hot benzene and alcohol, insol. water and alkalis (Spiegler, *B.* 17, 1575; Kipping, *C. J.* 57, 540).

**STEAROXYLIC ACID  $C_{17}H_{32}O_4$ .** Mol. w. 312. [86°]. Formed by the oxidation of stearolic acid (Overbeck, *A.* 140, 63; Hazura a. Grüssner, *M.* 9, 952). Plates or needles, sl. sol. cold alcohol.— $BaA'_2$ — $AgA'$ : crystalline powder.

**STEARYL-GLYCERIN *v.* GLYCERIN.**

**STEEL *v.* IRON**, vol. iii. p. 53, and **DICTIONARY OF APPLIED CHEMISTRY**, vol. ii. p. 360.

**STIBINE.** Synonym of *antimony hydride*, *v.* vol. i. p. 288.

**STILBENE *v.* DI-PHENYL-ETHYLENE.**

**STILBENE ALCOHOL *v.* HYDROBENZÖIN.**

**STILBENE DIBROMIDE *v.* DI-BROMO-PHENYL-ETHANE.**

**STILBENE DICARBOXYLIC ACID *v.* DI-PHENYL-MALÉIC ACID.**

**STILBENE DICHLORIDE *v.* DI-CHLORO-PHENYL-ETHANE.**

**STOICHIOMETRY.** The laws of chemical combination, and their application to chemical calculations; *v.* COMBINATION, CHEMICAL, LAWS OF, vol. ii. p. 235.

**STORAX.** A balsam produced by *Styrax officinalis*, a shrub growing in the Levant. It occurs in two varieties, liquid storax and reed storax, the latter containing a large quantity of bark. Liquid storax is a brownish-yellow sticky mass containing styrene, styracin, cinnamic acid, phenylpropyl cinnamate, a little ethyl cinnamate, a substance [65°] smelling like vanilla (possibly ethyl-vanillin), and (a) and (b)-storesinol (W. von Miller, *N. R. P.* 24, 1; *B.* 9, 274; *A.* 188, 184; 189, 838).

(a)-Storesinol  $C_{23}H_{38}O_2$  i.e.  $C_6H_{13}(OH)_2$  [160°–168°]. Amorphous, *v.* sol. dilute  $KOH$ aq.

**L L**

but conc. KOH aq. ppts.  $C_{26}H_{20}O_4K$ . Yields a mono- and tri-acetyl derivative.

( $\beta$ )-Storesinol.  $[140^\circ-145^\circ]$ . Amorphous. Forms amorphous  $C_{26}H_{20}O_4K$ , which is more sol. water than its ( $\alpha$ )-isomeride.

**STRONTIA.** Oxide of strontium (*q.v.* p. 516).

**STRONTIUM.** Sr. At. w. 87.3. Mol. w. not known. Very little known about properties. Doubtful if approximately pure Sr has yet been isolated. S.G. c. 2.4 to 2.58 (Franz, *J. pr.* 107, 253; Matthiessen, *J.* 8, 324). For emission-spectrum *v. B.* A. 1834. 444. H.C.  $[Sr, O] = 123, 440$  (*Th.* 3, 258).

**Occurrence.**—Compounds of Sr are widely distributed, but not in very large quantities.  $SrCO_3$  occurs in small quantities in all specimens of *aragonite*; very small quantities are found in many *calc-spars*, *marbles*, and *dolomites*.  $SrSO_4$  is an ingredient of many *heavy spars*.  $SrCO_3$  is found as *strontianite*, and  $SrSO_4$  as *celestine* in a few localities; *brewsterite* contains Sr silicate, with silicates of Ba or Ca. Traces of  $SrSO_4$  and  $SrCl_2$  are found in many mineral springs, in some hard river-waters, in sea-water, and in the ashes of certain plants, especially *Fucus vesiculosus*.

**Historical.**—A mineral found at Strontian, a village in Argyshire, in 1787, and supposed to be barium carbonate, was observed to colour flame reddish by Crawford and Cruikshank in 1790 (*Mem. Manchester Soc.*). The supposition made by C. a. C. that the mineral contained a new element was confirmed by Hope (*T. E.* 4, 3), Klaproth (*Crell's Ann.* 1793 [ii.] 189; 1794 (i.) 99), and Kirwan-Higgins (*Crell's Ann.* 1795 (ii.) 119, 205). The metal was isolated by Davy in 1808 (*T.* 1808. 345).

**Formation.**—1. By electrolysis moist  $SrO$ ,  $H_2$  or  $SrCl_2$  in contact with Hg and a little naphtha, and heating the amalgam so formed (Davy, *T.* 1808. 345).—2. By heating saturated  $SrCl_2$  aq. with Na amalgam to  $90^\circ$ , quickly washing the Sr amalgam so formed, drying it by filter paper, and distilling off the Hg in a stream of H (Franz, *J. pr.* 107, 253).—3. By heating  $SrO$  or  $SrO_2 \cdot H_2O$  intimately mixed with Mg powder, a mixture of Sr with MgO is obtained (Winkler, *B.* 23, 125, 2647).

**Preparation.**—A porous clay cylinder is placed in a crucible, and  $SrCl_2$  mixed with a little  $NH_4Cl$  is placed in the crucible and in the cell, so that when the mixture is fused the surface of it is at a higher level in the cell than in the crucible. A cylinder of sheet iron surrounding the cell serves as the positive electrode, and an iron wire passing through a tobacco pipe, the bowl of which dips under the molten mixture in the cell, serves as the negative electrode. The crucible is heated till the mixture of  $SrCl_2$  and  $NH_4Cl$  melts, temperature being kept so that there is always a solid crust on the surface of the mixture in the porous cell. A current from 5 or 6 Bunsen cells is passed through the molten mass; Sr is separated and runs into small pieces, which are protected from the air by the solid crust of  $SrCl_2$  and  $NH_4Cl$ ; the pieces of Sr are removed by an iron spoon and kept under petroleum.

For the preparation of pure Sr salts from *strontianite* *v. Barthe* a. Falières (*Bl.* [3] 7, 104).

**Properties.**—A yellowish-white metal, somewhat harder than Ca or Pb; can be beaten into

thin leaves; melts at full red heat. According to Mallet (*A.* 190, 62), Sr is slightly volatilised at a very high temperature. Easily oxidised by exposure to air; decomposes cold water rapidly; dissolves in dilute acids, not in  $HNO_3$  aq. giving salts and H. Combines directly with S and the halogens. Sr is a strongly positive metal, less positive than the alkali metals and Ca, but more positive than Mg; it is closely related to Ca and Ba, less closely to Mg; it also shows resemblances to Zn, Cd, and Hg (*v. ALKALINE EARTHS, METALS OF THE*, vol. i. p. 112; and *MAGNESIUM GROUP OF ELEMENTS*, vol. iii. p. 163). The atomic weight of Sr has been determined (1) by determining  $CO_2$  in  $SrCO_3$  (Stromeyer, *S.* 19, 228 [1816]; Salvétat, *C. R.* 17, 318 [1843]); (2) by ppg. Cl from  $SrCl_2$  by Ag (Rose, *S.* 19, 228 [1816]; Pelouze, *C. R.* 20, 1047 [1845]; Marignac, *A.* 106, 168 [1858]; Dumas, *A. Ch.* [3] 55, 191 [1859]); (3) by determining water in  $SrCl_2 \cdot 6H_2O$  (Marignac, *A.* 106, 168 [1858]); (4) by transforming  $SrCl_2 \cdot 6H_2O$  into  $SrSO_4$  (Marignac, *l.c.*). The S.I. of Sr has not been determined directly. The V.D. of no compound of Sr has been determined.

**Reactions and Combinations** (*v. Bunsen*, *A.* 94, 111).—1. Exposed to air or oxygen rapidly forms  $SrO$ , or  $SrO_2 \cdot H_2O$ , if moisture is present.—2. Burns brilliantly when heated in oxygen, sulphur vapour, chlorine, bromine, or iodine vapour; also in dry carbon dioxide.—3. Decomposes cold water rapidly, giving off H and forming  $SrO_2 \cdot H_2O$ .—4. Dissolves rapidly in dilute hydrochloric or sulphuric acid; reacts slowly with conc. sulphuric acid; scarcely acted on by nitric acid, even when hot and conc.—5. Reduces silica and silicates when heated therewith to full redness.

Strontium, antimonate of; *v. vol.* i. p. 286.

Strontium, arsenates of; *v. vol.* i. p. 309.

Strontium, arsenite of; *v. vol.* i. p. 307.

Strontium, borates of; *v. vol.* i. p. 530.

Strontium, bromide of,  $SrBr_2$ . Mol. w. not determined. By heating Sr in Br. By dissolving  $SrCO_3$  in  $HBr$  aq. and evaporating, long white needles of the hydrate  $SrBr_2 \cdot 6aq$  are obtained (Löwig, *Mæg. Pharm.* 33, 7); S.G. 2.358 (Favre a. Valson, *C. R.* 77, 579); these crystals do not effloresce over  $H_2SO_4$  (Rammelsberg, *P.* 55, 238), but on heating give off their water, leaving  $SrBr_2$  as a white solid, S.G. 3.985 (F. a. V., *l.c.*), that melts at red heat without decomposition (R., *l.c.*).  $[Sr, Br] = 157,700$  (*Th.* 3, 258). Carnelley (*C. J.* 33, 279) gives melting-point as c.  $630^\circ$ . Combines with ammonia to form  $2SrBr_2 \cdot NH_3$  (Rammelsberg, *P.* 55, 238).

Strontium, chloride of,  $SrCl_2$ . Mol. w. not determined.

**Formation.**—1. By burning Sr in Cl.—2. By passing Cl over hot  $SrO$  (Weber, *P.* 112, 619).—3. By heating  $SrO$  in a stream of  $HCl$  (Chevreul, *A. Ch.* 84, 285).—4. By decomposing  $SrCO_3$  by conc.  $CaCl_2$  aq. or  $MgCl_2$  by heating together, then dissolving out  $SrCl_2$  and crystallising ( $SrCO_3 + MgCl_2 \cdot aq = SrCl_2 \cdot aq + MgO + CO_2$ ; Wackenroder's Patent; *v. B.* 19, Ref. 638).—5. By heating a mixture of  $SrSO_4$ ,  $CaCl_2$ , and charcoal with a little chalk, lixiviating, and crystallising ( $SrSO_4 + CaCl_2 + 4C = SrCl_2 + CaS + 4CO$ ; Mactear, *D. J. F.* 262, 288).

**Preparation.**—*Strontianite* ( $\text{SrCO}_3$ ) is dissolved in  $\text{HClAq}$ , the solution is digested in absence of air with more  $\text{SrCO}_3$  (to remove iron, &c.), poured off and evaporated to the crystallising point; the crystals of  $\text{SrCl}_2$  6aq that separate are purified by re-crystallisation, then dried and heated to  $100^\circ$  until they cease to lose weight.

**Properties.**—A white, crystalline powder, with a sharp, bitter taste. Melts at  $825^\circ$  (Carnelley, *C. J.* 33, 280) to a glass-like mass with an alkaline reaction. S.G. 2.96 at  $0^\circ$ ; 2.77 at m.p. (Quincke, *P.* 133, 141). S. 44.2 at  $0^\circ$ , 48.3 at  $10^\circ$ , 53.9 at  $20^\circ$ , 60 at  $30^\circ$ , 66.7 at  $40^\circ$ , 74.4 at  $50^\circ$ , 83.1 at  $60^\circ$ , 87.5 at  $65^\circ$ , 88.8 at  $66.5^\circ$ , 89.6 at  $70^\circ$ , 92.4 at  $80^\circ$ , 96.2 at  $90^\circ$ , 101.9 at  $100^\circ$ , 109.1 at  $110^\circ$ , 116.4 at  $118.8^\circ$ ; saturated  $\text{SrCl}_2\text{Aq}$  boils at  $118.8^\circ$  (Mulder). Gerlach (*Fr.* 8, 245) gives the following data:—

S.G. $\text{SrCl}_2\text{Aq}$	P.a. $\text{SrCl}_2$	S.G. $\text{SrCl}_2\text{Aq}$	P.a. $\text{SrCl}_2$
1.0453	5	1.2580	25
1.0929	10	1.3220	30
1.1439	15	1.3633	33
1.1989	20		

$\text{SrCl}_2$  is insol. absolute alcohol; it dissolves in aqueous alcohol in proportion to the amount of water present (Gerardin, *A. Ch.* [4] 5, 156).  $[\text{Sr}, \text{Cl}] = 184,550$ ;  $[\text{Sr}, \text{Cl}^2, \text{Aq}] = 195,690$  (*Th.* 3, 258). For connection between solubility in water of  $\text{SrCl}_2$  and temperature v. Etard (*C. R.* 113, 854).

**Reactions and Combinations.**—1. Heated to redness in water vapour,  $\text{HCl}$  is given off and  $\text{SrO}$  remains (Kraus, *P.* 43, 133; Kahnheim, *J.* 1861, 149).—2. Heated with bromine to  $200^\circ$  is partially decomposed to  $\text{SrBr}_2$  (Potilitzin, *B.* 7, 733; 8, 766); the amount of decomposition varies with temperature and the relative masses of  $\text{SrCl}_2$  and  $\text{Br}$ .—3. Combines with water. Solution of  $\text{SrCO}_3$  in  $\text{HClAq}$  evaporated yields long, six-sided, hexagonal needles of the *hexahydrate*  $\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$ ; S.G. 1.933 at  $17^\circ$ . By keeping these crystals over  $\text{H}_2\text{SO}_4$  in *vacuo* for some months the *dihydrate*  $\text{SrCl}_2 \cdot 2\text{H}_2\text{O}$  is formed.—4. Combines with ammonia to form  $\text{SrCl}_2 \cdot 8\text{NH}_3$  (H. Rose, *P.* 20, 155).

Strontium, cyanide of; v. vol. ii. p. 347.

Strontium, ferrocyanide of; v. vol. ii. p. 337.

Strontium, fluoride of,  $\text{SrF}_2$ . A white, crystalline powder; scarcely sol. water or  $\text{HFAq}$ . Prepared by the action of  $\text{HFAq}$  on  $\text{SrO}$  or  $\text{SrCO}_3$  (Berzelius, *P.* 1, 20); also by fusing 2 parts  $\text{SrCl}_2$  with 1 part  $\text{NaF}$  and 1 part  $\text{NaCl}$ , and lixiviating the product (Röder, *Dissertation* [Göttingen, 1863] 14; Feldmann, *B.* 21, *Ref.* 866 (*Patent*)). Poulenc (C. R. 116, 987) obtained  $\text{SrF}_2$  as an amorphous powder, by the reaction of  $\text{HFAq}$  and  $\text{SrCl}_2\text{Aq}$ ; S.G. 2.44; partly decomposed to  $\text{SrO}$  by heating in air to  $c. 1000^\circ$ . By fusing with alkali chlorides, or with  $\text{KHF}_4$ , P. obtained  $\text{SrF}_2$  in regular octahedral crystals.

Strontium, hydride of. By heating to redness a mixture of 103 parts  $\text{SrO}$  (made from  $\text{SrCO}_3$ ) with 24 parts  $\text{Mg}$  powder, in an iron tube, in an atmosphere of  $\text{H}_2$ , Winkler (*B.* 24, 1975) obtained a greyish-brown powder that quickly oxidised in air to  $\text{SrO}_2\text{H}_2$ , with evolution of  $\text{H}_2$ , and was decomposed very rapidly by water or  $\text{HClAq}$  with violent evolution of  $\text{H}_2$ . Analyses

indicated that the substance might be a mixture of  $c. 66$  p.c.  $\text{SrH}$  with  $c. 29$  p.c.  $\text{MgO}$ ,  $c. 4$  p.c.  $\text{SrO}$ , and a very little  $\text{Mg}$ .

Strontium, hydrosulphide of,  $\text{SrS}_2\text{H}_2 \cdot x\text{H}_2\text{O}$ . By saturating  $\text{SrOaq}$  with  $\text{H}_2\text{S}$  and evaporating in *vacuo* over  $\text{H}_2\text{SO}_4$ ; or by dissolving  $\text{SrS}$  in water, evaporating, filtering from  $\text{SrO}_2\text{H}_2$ , and evaporating over  $\text{H}_2\text{SO}_4$  in *vacuo*. Large, white crystals; melts when heated in water of crystallisation, and then gives  $\text{SrS}$ . Aqueous solution boiled gives off all  $\text{H}_2\text{S}$  and forms  $\text{SrO}_2\text{H}_2$  (v. Rose, *P.* 55, 430; Berzelius, *P.* 6, 442).

Strontium, hydroxide of,  $\text{SrO}_2\text{H}_2$ . Mol. w. not determined. Prepared by the action of water on  $\text{SrO}$ . Also by heating *celestine* ( $\text{SrSO}_4$ ) with charcoal, dissolving  $\text{SrS}$  so formed in water, heating with  $\text{CuO}$  or  $\text{ZnO}$ , filtering from  $\text{CuS}$  or  $\text{ZnS}$ , evaporating to dryness, and heating to redness (*cf.* *Barium Hydroxide*, vol. i. p. 442).

A white solid; S.G. 3.625 (Filhol, *A. Ch.* [3] 21, 415). Sol. water, forming a markedly alkaline solution reacting similarly to  $\text{BaO}_2\text{H}_2\text{Aq}$  and  $\text{CaO}_2\text{H}_2\text{Aq}$ . Scheibler (*C. C.* [3] 13, 33) gives the following data, showing solubility in water, expressed in terms of  $\text{SrO}$ , and the hydrate  $\text{SrO}_2\text{H}_2 \cdot 8\text{H}_2\text{O}$ , dissolved:—

Temp.	S.			Temp.	S.		
	$\text{SrO}$	$\text{SrO}_2\text{H}_2 \cdot 8\text{H}_2\text{O}$	$\text{SrO}_2\text{H}_2 \cdot 8\text{H}_2\text{O}$		$\text{SrO}$	$\text{SrO}_2\text{H}_2 \cdot 8\text{H}_2\text{O}$	$\text{SrO}_2\text{H}_2 \cdot 8\text{H}_2\text{O}$
$0^\circ$	.35	.90		$55^\circ$	2.54	6.52	
5	.41	1.05		60	3.03	7.77	
10	.48	1.23		65	3.62	9.29	
15	.57	1.46		70	4.35	11.16	
20	.68	1.74		75	5.30	13.60	
25	.82	2.10		80	6.56	16.83	
30	1.00	2.57		85	9.00	23.09	
35	1.22	3.13		90	12.00	30.78	
40	1.48	3.80		95	15.15	38.86	
45	1.78	4.57		100	18.60	47.71	
50	2.13	5.46		101.2	19.40	49.75	

Dry  $\text{SrO}_2\text{H}_2$  takes up only traces of  $\text{CO}_2$  from the air (Heyer, *B.* 19, 2684); but the hydrate  $\text{SrO}_2\text{H}_2 \cdot \text{H}_2\text{O}$  absorbs  $\text{CO}_2$  till it is changed to  $\text{SrCO}_3$  (H., *l.c.*); according to Finkener (*B.* 19, 2958) a basic carbonate is formed.

The *octohydrate*,  $\text{SrO}_2\text{H}_2 \cdot 8\text{H}_2\text{O}$ , crystallises in tetragonal crystals ( $a : c = 1 : .6407$ ) from  $\text{SrOaq}$ ; S.G. 1.396 at  $16^\circ$ ; in air falls to powder, giving the *monohydrate*  $\text{SrO}_2\text{H}_2 \cdot \text{H}_2\text{O}$ , which loses  $\text{H}_2\text{O}$  at  $100^\circ$  (v. Finkener, *l.c.*; Müller-Erbach, *B.* 19, 2874; 20, 1628). Weisberg (*B.* 11, 511) says that  $\text{Cl}$  reacts with the hydrates of  $\text{SrO}_2\text{H}_2$  to give  $\text{SrCl}_2$  and  $\text{Sr}(\text{ClO}_4)_2$ .

Strontium, iodide of,  $\text{SrI}_2$ . A white solid; by dissolving  $\text{SrCO}_3$  in  $\text{HIAq}$ , evaporating, and heating the *hexahydrate*,  $\text{SrI}_2 \cdot 6\text{H}_2\text{O}$ , which crystallises out. S.G. 4.415; melts at red heat; strongly heated in air gives  $\text{SrO}$  and  $\text{I}$  (Crott, *J. pr.* 68, 420). Thomsen gives  $[\text{Sr}, \text{I}, \text{Aq}] = 143,460$  (*Th.* 3, 258).

Strontium, manganocyanide of; v. vol. ii. p. 342.

Strontium, nitride of. By heating  $\text{Sr}$  amalgam containing from 20 to 25 p.c.  $\text{Sr}$  (prepared by electrolysis and heating the product in *vacuo*) in a stream of  $\text{N}$ , Maquenne (*Bl.* [3] 7, 366) obtained a dark-coloured compound of  $\text{Sr}$  and  $\text{N}$  to which he gave the formula  $\text{Sr}_3\text{N}_4$ .

Strontium, oxides of. Two oxides have been isolated,  $\text{SrO}$  and  $\text{SrO}_2$ .

**STRONTIUM OXIDE**  $\text{SrO}$ . (*Strontium monoxide*. *Strontia*.) Mol. w. not known. Prepared by strongly heating  $\text{SrO}_2\text{H}_2$ ,  $\text{Sr(NO}_3)_2$ ,  $\text{SrCO}_3$  (Brügelmann, *Fr.* 29, 127; Heyer, *B.* 19, 2684); also by strongly heating  $\text{SrI}_2$  in air (Croft, *J. pr.* 68, 420). Best prepared similarly to  $\text{BaO}$  (v. **BARIUM MONOXIDE**, vol. i. p. 443). A grey-white, porous, infusible solid; prepared by heating  $\text{SrCO}_3$  or  $\text{SrO}_2\text{H}_2$  forms a mass of regular cubes with S.G. 4.75 referred to water at 4° (Brügelmann, *l.c.*). According to Moissan (*C. R.* 115, 1034),  $\text{SrO}$  melts to a transparent liquid at c. 3000°, and this solidifies to a crystalline mass. Thomsen gives  $[\text{Sr}_2\text{O}] = 128,440$  (*Th.* 3, 258). Dissolves in water (for data v. *Strontium hydroxide*); from this solution the octohydrated hydroxide  $\text{SrO}_2\text{H}_2 \cdot 8\text{H}_2\text{O}$  separates on evaporation. By passing moist air over  $\text{SrO}$  the monohydrated hydroxide,  $\text{SrO}_2\text{H}_2 \cdot \text{H}_2\text{O}$ , is formed (Heyer, *B.* 19, 2684).  $\text{SrO}$  is a strongly basic oxide, reacting with acids to form salts  $\text{SrX}$ , where  $\text{X} = \text{SO}_4$ ,  $2\text{NO}_3$ ,  $\frac{2}{3}\text{PO}_4$ , &c.

**STRONTIUM DIOXIDE**  $\text{SrO}_2$ . (*Strontium peroxide*.) Mol. w. not known. Addition of  $\text{H}_2\text{O}_2\text{Aq}$  to  $\text{SrO}_2\text{Aq}$  ppt. the octohydrate  $\text{SrO}_2 \cdot 8\text{H}_2\text{O}$  (Thénard, *A. Ch.* [2] 8, 312; Schöne, *B.* 6, 1172; cf. Conroy, *C. J.* [2] 11, 812). By drying this pp. at 100°  $\text{SrO}_2$  is obtained as a white powder, having similar properties to those of barium dioxide (q.v. vol. i. p. 443).  $\text{SrO}_2$  is not obtained by methods similar to those generally used for making  $\text{BaO}_2$ .

**Strontium, oxychloride of.** According to André (*A. Ch.* [6] 3, 66) crystals of the compound  $\text{SrCl}_2 \cdot \text{SrO} \cdot 9\text{H}_2\text{O}$  ( $= \text{Sr}_2\text{OCl}_2 \cdot 9\text{H}_2\text{O}$ ) are deposited from a mixture of saturated  $\text{SrCl}_2\text{Aq}$  and saturated  $\text{SrO}_2\text{Aq}$ ; the crystals are very unstable in air.

**Strontium, oxysulphide of.** Schöne (*P.* 117, 59) obtained  $\text{Sr}_2\text{S} \cdot \text{SrO} \cdot 12\text{aq}$  ( $\text{Sr}_2\text{OS} \cdot 12\text{aq}$ ) by slow oxidation of  $\text{SrS}_2\text{Aq}$ .

**Strontium, platincyanoide of;** v. vol. ii. p. 844.

**Strontium, salts of.** Compounds obtained by replacing *H* of acids by *strontium*. These compounds belong to the type  $\text{SrX}$ , where *X* is  $\text{SO}_4$ ,  $\text{CO}_3$ ,  $2\text{NO}_3$ ,  $\frac{2}{3}\text{PO}_4$ , &c. The *Sr* salts are very definite compounds; not many basic salts are known. The chief salts of oxyacids are the following: bromate and hypobromite, carbonate, chlorate, chlorite and perchlorate, chromate and dichromate, iodate and periodate, molybdate, nitrate, nitrite, and hyponitrite, selenate and selenites, sulphate, sulphite, thiosulphate, and thionates (v. **CARBONATES, NITRATES, &c.**).

**Strontium, selenide of.** Obtained as a white solid, rapidly decomposing in air with separation of *Se*, by heating a small quantity of  $\text{SrSeO}$ , in *H* to dull redness;  $[\text{Sr}, \text{Se}] = 87,160$  (Fabre, *C. R.* 102, 1469).

**Strontium, silicofluoride of,**  $\text{SrSiF}_6 \cdot 2\text{H}_2\text{O}$ . Four-sided prisms; S.G. 2.999; loses  $2\text{H}_2\text{O}$  when gently warmed; prepared by dissolving  $\text{SrCO}_3$  in  $\text{H}_2\text{SiF}_6\text{Aq}$  and evaporating (Berzelius, *Lehrbuch* [5th edit.], 3, 385). Fresenius (*Fr.* 29, 143) gives S. 3.2 at 15°; S. in alcohol (50 p.c. by vol.) .06 at 15°.

**Strontium, sulphides of.** Three sulphides have been isolated:  $\text{SrS}$ ,  $\text{Sr}_2\text{S}$ , and  $\text{SrS}_2$ .

**STRONTIUM MONOSULPHIDE**  $\text{SrS}$ . Formed by heating together *Sr* and *S* in the ratio 87:32;

also by reducing  $\text{SrSO}_4$  by charcoal; also by passing  $\text{CS}_2$  vapour mixed with  $\text{H}_2$ ,  $\text{H}_2\text{S}$ , or  $\text{CO}$ , over red-hot  $\text{SrCO}_3$  (cf. **BARIUM MONOSULPHIDE**, vol. i. p. 444). A white powder, which slowly becomes yellowish when exposed to air. Does not phosphoresce (Schöne, *P.* 117, 59). For phosphorescence of  $\text{SrS}$  mixed with small quantities of other salts v. Becquerel (*C. R.* 107, 892). Sabatier (*A. Ch.* [5] 22, 5) gives  $[\text{Sr}, \text{S}] = 49,600$ .  $\text{SrS}$  does not combine with *S* when heated therewith, but polysulphides are formed by boiling an aqueous solution of  $\text{SrS}$  with *S* (Schöne, *P.* 117, 59).  $\text{SrS}$  dissolves in water; on crystallising  $\text{SrO}_2\text{H}_2$  separates and  $\text{SrS}_2\text{H}_2$  remains in solution (H. Rose, *P.* 55, 430).

**STRONTIUM TETRASULPHIDE**  $\text{SrS}_4 \cdot x\text{H}_2\text{O}$ . The hexahydrate,  $\text{SrS}_4 \cdot 6\text{H}_2\text{O}$ , is obtained, as a reddish crystalline solid, by boiling 100 parts  $\text{SrS}$  in water, and evaporating the solution *in vacuo* at a temperature not higher than 16°. From a solution at 20°-25° the dihydrate  $\text{SrS}_2 \cdot 2\text{H}_2\text{O}$  separates. An aqueous solution of  $\text{SrS}_4$  oxidises in air to the oxysulphide  $\text{SrO} \cdot \text{SrS}_2 \cdot 12\text{aq}$ , and then to  $\text{SrS}_2\text{O}_3$ , while *S* separates and some  $\text{SrCO}_3$  is formed (Schöne, *P.* 117, 59).

**STRONTIUM PENTASULPHIDE**  $\text{SrS}_5 \cdot x\text{H}_2\text{O}$ . An amorphous, yellowish, hygroscopic solid; formed by evaporating a solution of  $\text{SrS}$ , saturated with *S* in the cold. After drying at 100°,  $\text{CS}_2$  dissolves out  $\frac{1}{4}$ th of the *S*, leaving  $\text{SrS}_4$  (Schöne, *l.c.*).

**Strontium, sulphydrate of;** v. **STRONTIUM HYDROSULPHIDE**, p. 615.

**Strontium, sulphocyanide of;** v. vol. ii. p. 352. M. M. P. M.

**STROPHANTHIN**  $\text{C}_{20}\text{H}_{31}\text{O}_2$  (A.);  $\text{C}_{20}\text{H}_{31}\text{O}_2$  (F.).  $[\alpha]_D = 30^\circ$ . Extracted by alcohol at 70° from the seeds of *Strophanthus hispidus* (Galloys, *C. R.* 84, 261; Fraser, *Ar. Ph.* [3] 3, 229; Pr. E. 124, 370; Ph. [3] 18, 69; Elborne, *Ph.* [3] 17, 743; 18, 219; Gerrard, *Ph.* [3] 17, 923; Arnaud, *C. R.* 107, 179; Gley, *C. R.* 107, 848). White micaceous crystals, sol. water, v. sol. alcohol, insol. ether. Dextrorotatory. Bitter. Resembles ouabain in toxic effects. Decomposed by boiling dilute acids (even  $\text{H}_2\text{S}$ ) into glucose and crystalline strophanthidin, which yields a resin on further boiling with dilute  $\text{H}_2\text{SO}_4$  (F.).  $\text{H}_2\text{SO}_4$  and a trace of  $\text{FeCl}_3$  gives a reddish-brown pp., changing to emerald-green (Helbing, *Ph.* [3] 17, 924).

**STRUTHIIN** v. **SAPONIN**.

**STRYCHNIC ACID**  $\text{C}_{20}\text{H}_{27}\text{NO}(\text{NH})\text{CO}_2\text{H}$ . Formed from strychnine, alcohol, and *Na* at 50°-55° (Tafel, *A.* 264, 50). When heated in a current of *H* at 190° it changes to strychnine.  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  give a brown-red colour or pp.

**Nitrosamine**  $\text{C}_{20}\text{H}_{27}\text{NO}(\text{N.NO})\text{CO}_2\text{H}$ . Gelatinous pp. Exhibits Liebermann's reaction.

**Methylo-iodide**

$\text{C}_{20}\text{H}_{22}\text{N}(\text{MeI})\text{O}(\text{NH})\text{CO}_2\text{H}$ . Formed from methyl-strychnine and *HI* (Tafel, *A.* 264, 55). Colourless needles (containing aq.), v. sl. sol. cold alcohol and cold water.—*NaA* aq.; v. e. sol. water, m. sol. alcohol. Converted by *MeI* into crystalline  $\text{C}_{20}\text{H}_{22}\text{N}(\text{MeI})(\text{NMe})\text{CO}_2\text{Me}$ .

**Methyl-strychnic acid.** **Methylo-iodide.**  $\text{C}_{20}\text{H}_{22}\text{N}(\text{MeI})\text{O}(\text{NMe})\text{CO}_2\text{H}$ . Formed from dimethyl-strychnine and *HI* (Tafel, *A.* 264, 58). Needles, m. sol. boiling water and hot alcohol,

**Deoxystrychnic acid**  $C_{20}H_{29}N(NH).CO_2H$  aq. Formed by heating deoxystrychnine with alcoholic NaOEt at 180° (Tafel, A. 268, 253). Needles (containing aq) (from dilute  $H_2SO_4$ ) or anhydrous prisms (from alcohol), sl. sol. hot water. Quickly converted by acids into deoxystrychnine. Yields a nitrosamine.

**Isostrychnic acid**  $C_{20}H_{29}NO(NH).CO_2H$ . Formed from strychnine, Na, and alcohol at 70°. Got also by heating strychnine with baryta-water at 140° in absence of air. Minute needles.  $K_2Cr_2O_7$  and dilute  $H_2SO_4$  form a brown liquid on heating, and a brown pp. with excess of  $K_2Cr_2O_7$ .— $HA'HI$  aq: prisms, m. sol. cold water and alcohol, insol. ether.

**Nitroso-derivative**  
 $NO.C_{20}H_{29}NO(NH).CO_2H$  aq. Sol. alkalis, but ppd. by  $CO_2$ . Yields a nitrosamine, which gives Liebermann's reaction with phenol and  $H_2SO_4$ .— $HA'HCl$ : needles, insol. water.

**Methylo-iodide**  
 $C_{20}H_{27}N(MeI)O(NH).CO_2H$ . Crystalline, m. sol. hot water.— $NaA'$ : minute needles. Converted by methyl iodide at 100° into crystalline  $C_{20}H_{27}N(MeI)O(NMe).CO_2Me$  2aq.

**Methyl-isostrychnic acid**  
 $C_{20}H_{29}NO(NMe).CO_2H$ . From isostrychnic acid hydroiodide and MeI at 100° (Tafel, A. 268, 240). Small colourless prisms (containing 2aq). Its alkaline solution is not coloured by air (difference from isostrychnic acid).

**Methylo-iodide**  
 $C_{20}H_{27}N(MeI)O(NMe).CO_2H$  aq [271°–275°]. Formed from methyl-strychnine methylo-iodide and HI (Tafel, A. 264, 77). Needles, m. sol. hot water and hot alcohol, insol. ether.

**Nitroso-methyl-isostrychnic acid**  
 $NO.C_{20}H_{27}ON(NMe).CO_2H$ . Formed from the preceding acid, alcohol, HCl, and amyl nitrite. Green needles (from benzene). When heated with benzoic aldehyde and ZnCl<sub>2</sub> it gives a green mass, which dyes like malachite green. Diazo-benzene chloride forms a brownish-orange dye.

**STRYCHNINE**  $C_{21}H_{27}N_2O_2$ . Mol. w. 334. [221°] (Blyth); [284°] (Claus a. Glassner, B. 14, 773); [268°] (Loebisch a. Schoop, M. 6, 858); [269°] (Stoehr). (270° at 5 mm.). S.G.  $\frac{1}{4}$  1.359 (Clarke, Am. 2, 174). S. 0.15 in the cold; 0.4 at 100°. S. 0.14 in the cold (Dragendorff, J. 1865, 739); 0.25 at 14.5° (Crespi, G. 13, 175). S. (alcohol) 3 at 8°; 1.8 at 78°. S. (95 p.c. alcohol) 936. S. (ether) 08. S. (benzene) 607. S. (isoamyl alcohol) 53 at 12°; 4.3 at 99°. Occurs in nux vomica, in St. Ignatius beans, in the wood of *Strychnos Colubrina*, in *Strychnos Tieute*, and in other species of *Strychnos* (Pelletier a. Caventou, A. Ch. [2] 10, 142; 26, 44; Pelletier a. Dumas, A. Ch. [2] 24, 176; Liebig, A. 47, 171; 49, 244; Regnault, A. Ch. [2] 68, 113; Gerhardt, Rev. Scient. 10, 192; Nicholson a. Abel, C. J. 2, 241; Henry, Ph. 8, 401; Corriol, Ph. 11, 492; Robiquet, Ph. 11, 580; Henry, jun., J. Ph. 16, 752; Berlekorn, Z. [2] 2, 443; Shenstone, Ph. [3] 8, 445). Occurs also in the bark of *Erythrophloeum guineense*, from which the pigmies of Central Africa prepare their arrow-poison (Holmes, Ph. [3] 21, 921).

**Preparation**.—1. The nuts (1 kilo) are softened by steam, dried, powdered, and digested with alcohol (5 kilos of S.G. 856) acidulated with

$H_2SO_4$  (45 g.). Lime is added to the filtrate; and, after standing, the decanted liquid evaporated; the residue dissolved in dilute acid; and the filtrate ppd. by ammonia. The strychnine is separated from brucine by crystallisation from alcohol (Henry).—2. The dilute alcoholic extract of nux vomica is evaporated to a small bulk and ppd. by lead acetate. The filtrate is mixed with magnesia and left for a few days. The pp. is dissolved in alcohol of 83 p.c. and evaporated to crystallisation. Strychnine is first deposited, and afterwards brucine. The bases are further purified by crystallisation of their nitrates, the nitrate of strychnine separating first.

**Properties**.—Trimetric prisms, permanent in the air and not altered by light. Levorotatory, the rotation varying greatly with the nature of the solvent (Hoorweg, A. 166, 76; Tykociner, R. T. C. 1, 146). The dispersive power is constant (Grimbert, J. Ph. [5] 16, 295). At 169° it forms a sublimate of minute needles (Blyth). Very bitter. Alkaline in reaction. Strychnine is a violent poison, acting on the spinal cord and producing convulsions (Lovett, J. Physiol. 9, 99). 0.3 g. may be fatal. Strychnine dissolves with difficulty in acids, the solubility being greater the more dilute the acid; when a conc. solution of a strychnine salt is slightly acidified a pp. is formed which dissolves in excess of acid, forming a solution which yields a pp. on dilution. Thus  $H_2SO_4$  added to a conc. solution of strychnine sulphate ppts. the acid sulphate  $B'H_2SO_4$ , the mother-liquor retaining .113 p.c. of salts. HCl added to a solution of strychnine hydrochloride ppts.  $B'HCl1\frac{1}{2}$  aq in needles, the mother-liquor retaining .413 p.c. of salt (Hanriot a. Blarez, C. R. 96, 1504). Strychnine is readily soluble in dilute hypophosphorous acid (Jones, Ph. [3] 20, 256). KCy added to a solution of a salt of strychnine ppts. the pure base (Flückiger, N. J. P. 38, 138; Weith, B. 4, 527). A solution of ICl gives a yellow pp. v. sol.  $HCl$  aq, from which it crystallises on cooling (Dittmar, B. 18, 1612).

**Reactions**.—1. Dry distillation yields carbazole,  $H, C_8H_5$ , and  $C_8H_7$  (Loebisch a. Schoop, M. 7, 614).—2. Distillation with lime yields (B)-methylpyridine, methyl-indole (scatole),  $C_8H_7$ ,  $NEtH_2$ , and  $NH_3$  (Stoehr, B. 20, 810, 1108, 2729; J. pr. [2] 42, 405).—3. Distillation with soda-lime gives carbazole, scatole, and (B)-methylpyridine (Loebisch a. Malfatti, M. 9, 628).—4. Distillation with KOH gives indole (Goldschmidt, B. 15, 1977) and batyric acid (Loebisch a. Schoop, M. 7, 93).—5. Distillation with zinc-dust at 400° *in vacuo* yields solid  $C_{21}H_{27}N_2O$ , which dissolves in alcohol with blue fluorescence, and gives no colour with  $K_2Cr_2O_7$  and  $H_2SO_4$ . Zinc-dust at a red heat gives  $H, C_8H_5$ ,  $C_8H_7$ ,  $NH_3$ , and carbazole (Loebisch a. Schoop, M. 7, 609), and (7)-lutidine (Scichilone a. Magnanini, G. 12, 444).—6. Alkaline  $KMnO_4$  yields oxalic acid,  $CO_2$ ,  $NH_3$ , and a crystalline acid [195°] (Hooogewerff a. Van Dorp, R. T. C. 2, 181). Half the nitrogen is given off as ammonia (Wanklyn a. Chapman, O. J. 21, 161).—7.  $KMnO_4$  in dilute acid solutions yields an amorphous acid  $C_{21}H_{27}NO_2$  aq (?) (Plugge, R. T. C. 2, 270), which yields amorphous  $C_{21}H_{27}AgNO_2$  aq (Hanriot, C. R. 96, 1671).—8. By treatment with  $CrO_3$  and  $H_2SO_4$  it yields the same oxidation product  $C_{21}H_{27}N_2O_2$  as that ob-

tained from brucine under the same treatment (Hanssen, *B. 18*, 1917).—9.  $\text{PbCl}_2$  (1 pt.) acting on strychnine hydrochloride (8 pts.) under boiling chloroform yields a compound crystallising from benzene in needles [224°], possibly penta-chloro-strychnine (Stoehr, *J. pr.* [2] 42, 414).—10. Boiling  $\text{HNO}_3$  forms cacostrychnine and picric acid (Shenstone, *C. J.* 47, 142); nitric acid forms 20 p.c. of di-nitro-di-oxy-quinoline carboxylic acid  $\text{C}_{17}\text{H}_{12}\text{N}_4\text{O}_8$ , which yields  $\text{KA}'$ , is reduced by  $\text{SnCl}_2$  to  $\text{C}_{17}\text{H}_{12}\text{N}_4\text{O}_4$  (a body having acid and basic properties), and when heated with water is split up into  $\text{CO}_2$  and di-nitro-di-oxy-quinoline (Tafel, *B. 26*, 353).—11. *Baryta water* in sealed tubes at 140° forms two bases,  $\text{C}_{21}\text{H}_{26}\text{N}_4\text{O}_4$  and  $\text{C}_{21}\text{H}_{28}\text{N}_4\text{O}_4$ , both crystallising from water (Gal. a. Etard, *C. R.* 87, 362).—12. *Alloxan* added to a solution of strychnine in a saturated solution of  $\text{SO}_2$  forms small colourless prisms of  $\text{B}'\text{C}_7\text{H}_7\text{N}_4\text{O}_4\text{H}_2\text{SO}_4$  (Pellizzari, *A.* 248, 150).—13. *Iodoform* (5 g.) and strychnine (12 g.) dissolved in hot alcohol (500 c.c.) deposit on cooling crystals of  $\text{B}'\text{CHI}_3$ , sol. ether and chloroform, but decomposed by light, hot water, and dilute acids (Lextrait, *C. R.* 92, 1057).—14. *Chloro-acetic acid* at 180° forms  $\text{C}_{21}\text{H}_{26}\text{N}_4\text{O}_4$ , a base which crystallises in silky needles, v. sol. hot water and alcohol, insol. ether (Roemer, *Z.* 1871, 435). It yields  $(\text{C}_{21}\text{H}_{26}\text{N}_4\text{O}_4)_2\text{PtCl}_6$ .—15.  $\text{AcCl}$  forms  $\text{B}'\text{AcCl}$ , which gives  $(\text{B}'\text{AcCl})_2\text{PtCl}_6$  (Konrad, *J.* 1874, 876).—16. *Chloro-acetone* at 135° yields  $\text{B}'\text{C}_7\text{H}_7\text{ClO}$ , S. 6.5 at 15°, which yields  $(\text{B}'\text{C}_7\text{H}_7\text{ClO})_2\text{PtCl}_6$  2aq and  $\text{B}'\text{C}_7\text{H}_7\text{OSO}_2\text{H}$  1½aq (Konrad).—17. Aqueous  $\text{SO}_2$  and alloxan give colourless prisms of  $\text{B}'\text{SO}_2\text{HC}_7\text{H}_7\text{N}_4\text{O}_4$  aq (Pellizzari, *G.* 18, 329).

*Detection*.—1.  $\text{H}_2\text{SO}_4$  forms a colourless solution which with  $\text{K}_2\text{Cr}_2\text{O}_7$  gives a blue colour, changing through violet and red to yellow (Otto, *A.* 60, 273). A drop of nitric acid and  $\text{PbO}_2$  or  $\text{MnO}_2$  may be used instead of  $\text{K}_2\text{Cr}_2\text{O}_7$  (Marchand, *B. J.* 24, 400; Davy, *A.* 88, 402).  $\text{KMnO}_4$  and  $\text{Ag}_2\text{O}$  act in like manner (Lyman, *Fr.* 12, 126). The colour with  $\text{H}_2\text{SO}_4$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  is not shown in presence of brucine (Hanriot, *C. R.* 97, 267), and is interfered with by quinine, morphine, and sugar (Brieger, *J.* 1850, 617; Vogel, *J.* 1853, 686; Flückiger, *Fr.* 28, 102).—2. A minute quantity of  $\text{KClO}_4$  added to a warm solution in dilute  $\text{HNO}_3$  gives a scarlet colour, changed by ammonia to brown, and then, on evaporation to dryness, becoming green (C. L. Bloxam, *C. N.* 55, 155).—3. Ammonium vanadate in  $\text{H}_2\text{SO}_4$  gives a blue colour, turned red by potash (Mandelin, *Fr.* 23, 240).—4. Chlorine water gives a pp.—5. Strychnine can be extracted from beer containing the poison by shaking with animal charcoal, the charcoal being subsequently extracted with alcohol (Graham a. Hofmann, *A.* 88, 39; cf. Wagner, *Fr.* 6, 387).—6. Obtained from acid liquids by adding ammonia and immediately shaking with chloroform (Cloetta, *Fr.* 5, 265; Gray, *Fr.* 12, 125).—7. A liquid containing strychnine sulphate may be shaken with benzene without loss of strychnine, but if the liquid be neutralised by magnesia the free strychnine can be extracted by benzene (Dragendorff, *Z.* [2] 2, 27).—8. A 1 p.c. solution of strychnine strongly acidified by  $\text{HCl}$  is ppd. by  $\text{KFeCy}$ , while brucine remains in solution (Holst a. Beckürte). This may be used as a volumetric

method. Strychnine and brucine may also be separated by crystallisation of their picrates (Gerock, *Ar. Ph.* [8] 27, 158).

*Salts*.— $\text{B}'\text{HCl}$  1½aq (Regnault, *A.* 26, 17). Trimetric crystals;  $\alpha:b:c = 484:1:468$  (Stoehr, *J. pr.* [2] 42, 399). Neutral in reaction. S. 2 at 22°. Lævorotatory.  $[\alpha]_D = -28^\circ$ .— $\text{B}'\text{HAuCl}_4$ . Orange crystals (from alcohol) (Nicholson a. Abel, *C. J.* 2, 241; *A.* 71, 84). Decomposed by boiling water (O. De Coninck, *Bl.* [2] 45, 131).— $\text{B}'_2\text{H}_2\text{PtCl}_6$ : golden scales (from alcohol). S.G.  $\frac{185}{4}$  1.779 (Clarke, *Am.* 2, 175).— $\text{B}'_2\text{H}_2\text{PtCl}_6$  aq (Schmidt, *A.* 180, 295).— $\text{B}'_2\text{H}_2\text{ZnCl}_6$  aq: prisms (Graffinghoff, *Bl.* [2] 4, 391).— $\text{B}'_2\text{H}_2\text{CdCl}_6$  (Galletly, *N. ed. P. J.* 4, 94).— $\text{B}'\text{HHgCl}_2$ . Crystals (from alcohol).— $\text{B}'\text{HgCl}_2$ : insol. alcohol, water, and ether.— $\text{B}'_2\text{H}_2\text{SO}_4\text{HgCl}_2$ .— $\text{B}'_2\text{H}_2\text{PdCl}_6$ : dark-brown needles (from alcohol).— $\text{B}'\text{HCl}_2\text{HgO}_2$ : tables (Brandis, *A.* 66, 268).— $\text{B}'\text{HgCy}_2$ : small prisms, sl. sol. water and alcohol, insol. ether.— $\text{B}'\text{HBraq}$ : needles, sol. water and alcohol.— $\text{B}'\text{HI}$  aq: plates or needles, almost insol. cold water.— $\text{B}'\text{HI}$ . S. 0.07 at 15°. Reddish-brown pp. got by adding a solution of I in  $\text{HIAq}$  to a salt of strychnine. Crystallises from alcohol in dark-brown needles with bluish metallic lustre. Dichroic (brown and yellow) in polarised light. M. sol. hot alcohol, sl. sol. chloroform, nearly insol.  $\text{CS}_2$  (Tilden, *C. J.* 18, 99; Herapath, *Pr.* 8, 149; Bauer, *Ar. Ph.* [3] 5, 289; Jørgensen, *A. Ch.* [4] 9, 115).— $\text{B}'\text{HHgI}_2$ : yellow tables (from alcohol) (Groves, *C. J.* 2, 97).— $\text{B}'\text{HF}_2$  2aq: prisms (Elderhorst, *A.* 74, 77).— $\text{B}'\text{HNO}_3$ : needles.— $\text{B}'\text{HClO}_4$  aq: prisms, sl. sol. cold water (Boedeker, *A.* 71, 62).— $\text{B}'_2\text{H}_2\text{SO}_4$  2aq: needles.— $\text{B}'_2\text{H}_2\text{SO}_4$ . Four-sided prisms. Lævorotatory  $[\alpha]_D = -26^\circ$ .— $\text{B}'_2\text{H}_2\text{SO}_4$  5aq: long thin prisms. Got by crystallisation between 109° and 95°.— $\text{B}'_2\text{H}_2\text{SO}_4$  6aq. Obtained by cooling a conc. solution to 95°–50° (Lextrait, *J. Ph.* [5] 6, 259; Rammelsberg, *B.* 14, 1231; cf. Baumhauser, *C. J.* 44, 485).— $\text{B}'_2\text{H}_2\text{CrO}_4$ : lemon-yellow needles, sl. sol. water and alcohol.— $\text{B}'_2\text{H}_2\text{S}_2\text{O}_4$  4aq. S. 3 in the cold. Formed by atmospheric oxidation of a mixture of strychnine, alcohol, and ammonium sulphide (How, *G. N.* 18, 232).— $\text{B}'_2\text{H}_2\text{S}_8$ . Formed from strychnine and alcoholic ammonium polysulphide (Hofmann, *B.* 1, 81; 10, 1087) and by atmospheric oxidation of a solution of strychnine in alcoholic  $\text{H}_2\text{S}$  (Schmidt, *B.* 5, 1267; 10, 1288; *A.* 180, 288). Orange needles, insol. water, alcohol, and ether.— $\text{B}'\text{H}_2\text{PO}_4$  2aq. S. 19. Needles (Anderson, *A.* 66, 56).— $\text{B}'_2\text{H}_2\text{PO}_4$  9aq: rectangular tables.— $\text{B}'\text{H}_2\text{AsO}_4$  ½aq. S. 7 in the cold; 20 in hot water.— $\text{B}'\text{HAsO}_4$ : efflorescent cubes. S. 3 in the cold; 10 at 100°.— $\text{B}'_2\text{H}_2\text{FeCy}_4$  4aq. Crystalline powder (Holst a. Beckürte, *Ar. Ph.* [3] 25, 313; cf. Brandis, *A.* 66, 257). By atmospheric oxidation in presence of water it is converted into strychnine and the ferricyanide (Beckürte, *B.* 18, 1235).— $\text{B}'\text{H}_2\text{FeCy}_4$ : white powder, sol. hot water. Acid in reaction.— $\text{B}'_2\text{H}_2\text{FeCy}_4$  6aq: golden prisms.— $\text{B}'_2(\text{H}_2\text{CoCy})_4$  4aq.— $\text{B}'_2(\text{H}_2\text{NiCy})_4$  8aq (Lee, *B.* 4, 789).— $\text{B}'_2\text{H}_2\text{PtCy}_4$  2aq: needles (from alcohol).—Oxalate  $\text{B}'_2\text{H}_2\text{C}_2\text{O}_4$ : flat needles.— $\text{B}'_2\text{H}_2\text{C}_2\text{O}_4$  ½aq.— $\text{B}'\text{H}_2\text{C}_2\text{O}_4$ .— $\text{B}'\text{HSCy}$ : long silky needles.— $\text{B}'\text{HSCyCr}(\text{SCy})_2\text{NH}_3$ . Red pp., v. sl. sol. hot water (Christensen, *J. pr.* [2] 45, 367).— $\text{B}'_2\text{H}_2\text{Pt}(\text{SCy})_4$ . Red crystals (Clarke

and Owens, *Am. J.* 3, 351).—Cyanurates:  $B'_2H_2O_4C_3N_3$  aq. [287°]. Prisms, sl. sol. water, m. sol. alcohol.— $B'_2H_2O_4C_3N_3$  aq. [295°]. Needles (Claus, *J. pr.* [2] 88, 228).—Nitroprusside. S. 12 (Davy, *Ph.* [3] 11, 756). Succinate  $B'_2O_4H_2O_4$  6 $\frac{1}{2}$ aq (Crespi, *G.* 13, 176).—Tartrates:  $B'_2C_2H_2O_4$ — $B'_2C_2H_2O_4$  4aq; white efflorescent needles (Arppe, *J. pr.* 53, 351).— $B'_2C_2H_2O_4$  7aq (Pasteur, *A. Ch.* [8] 88, 437).— $B'_2C_2H_2O_4$  3aq.— $B'_2C_2H_2(SbO)_2O_4$ . Needles (Stenhouse, *A.* 129, 25).—Malate  $B'_2C_2H_2O_4$  3 $\frac{1}{2}$ aq.—Pyrotartrate  $B'_2C_2H_2O_4$  3 $\frac{1}{2}$ aq.—Mucate  $B'_2C_2H_2O_4$ . Long needles (Ruhemann a. Dufton, *C. J.* 59, 754).

*Di-hydrate*  $B'2aq$ . *Strychnol*. Formed by warming strychnine with alcoholic NaOEt, adding water, and evaporating. The brown oily layer that forms is allowed to solidify, dissolved in water, and ppd. by  $CO_2$ . The pp. is dissolved in  $NH_4Aq$  and re-ppd. by expelling  $NH_3$  by air (Loebisch a. Schoop, *M.* 7, 83). The same body is got by heating strychnine (15 g.) with  $BaO_2H_2$  (30 g.) for 12 hours at 140° (Tafel, *B.* 23, 2737). Minute wedge-shaped needles, sl. sol. cold water, insol. alcohol and ether. Darkens at 150°. Sol. dilute alcohol and solutions of ammonium salts; sol. acids. Converted into strychnine on warming with dilute acids. Dilute  $HNO_3$  and a little  $NaNO_2$  give a crimson colour. Bromine water gives a pale-purple colour. Does not give the strychnine reaction with  $H_2SO_4$  and  $K_2Cr_2O_7$ . On heating at 100° with  $NaOMe$  and  $MeI$  it is converted into  $C_{22}H_{22}N_2O_4MeI$  2aq, crystallising in needles.

*Tri-hydrate* v. Reaction 10.

*Pentahydrate*  $B'5aq$ . [215°]. Got by heating strychnine with alcoholic NaOEt (Tafel). Needles, more soluble than the dihydrate. Becomes very hygroscopic when dried *in vacuo*.

*Benzoyl derivative*  $C_{22}H_{21}BzN_2O_4$ . V. sl. sol. water (Schützenberger, *A.* 108, 353; *C. R.* 47, 233).

*Methylo-iodide*  $B'MeI$ . S. 5 in the cold (Stahlschmidt, *P.* 108, 513). Poisonous (Crum Brown a. Fraser, *Tr. E.* 25). Formed by heating with  $MeI$  in sealed tubes. Pearly plates. Yields  $B'MeI$ , (Jørgensen, *J. pr.* [2] 3, 157) and the salts  $B'MeBr$ ,  $B'MeCl$  2aq,  $B'MePtCl_2$ ,  $B'MeAuCl_4$ ,  $B'Me_2SO$  5aq,  $B'MeHSO_4$ ,  $B'MeH_2PO_4$  2aq,  $B'MeCl_2\frac{1}{2}HgCl_2$ ,  $B'MeNO_3$ , and  $B'Me_2FeCy_2$ .

*Methylo-hydroxide*  $B'MeOH$  or  $C_{22}H_{22}O(NH) \ll NMe \gg O$ . Formed from  $B'MeI$  by successive treatment with  $Ag_2SO_4$  and baryta (Tafel, *B.* 23, 2733; *A.* 264, 62). Colourless crystals (containing 4aq), v. sol. alcohol, but a product containing less water soon separates. Poisonous. Gives the same colour-reactions as strychnine acid. Alcohol and Na yield a compound [158°].  $MeI$  forms  $B'MeImeOH$  crystallising in plates, decomposed at 280°.

*Isomeride of the methylo-hydroxide*  $C_{22}H_{22}N_2O_4$  7aq. Formed from the methylo-iodide of isostrychnine acid,  $Ag$ , and  $Ag_2O$  at 40° (Tafel, *A.* 264, 81). Colourless needles; v. s. sol. hot water and alcohol, insol. ether.

*Methyl-strychnine methylo-hydroxide*  $C_{22}H_{22}N_2O_4$  i.e.  $C_{22}H_{22}O(NMe) \ll NMe \gg O$ . Formed from  $B'MeImeOH$  by successive treat-

ment with  $Ag_2SO_4$  and baryta. Got also by the action of  $Ag_2O$  on the methylo-iodide of methyl-strychnine acid (Tafel, *B.* 23, 2735; *A.* 264, 66). Prisms (containing 6aq), v. sol. hot water and alcohol, nearly insol. ether. Gives a blood-red colour with  $HNO_3$ ,  $CrO_3$ , or  $FeCl_3$ . Forms with acids salts which differ from those prepared by the action of silver salts on  $B'MeImeOH$ . Forms a crystalline nitroso-derivative, v. sol. water and warm alcohol, forming a yellow solution changed by  $NaOH$  to brownish-red and olive-green.  $HI$  yields the methylo-iodide of methyl-strychnine acid. Diazobenzene sulphonic acid gives a brownish-red dye.—Hydroiodide. S. 7. Plates.—Methyloiodide  $C_{22}H_{21}N_2IO_4$ . S. 1. Needles.

*Isomeride of methyl-strychnine methylo-hydroxide*  $C_{22}H_{22}N_2O_4$  3aq. Formed from the methylo-hydroxide of methyl-isostrychnine ether (Tafel, *A.* 264, 82). Crystals, v. sol. hot water and alcohol, insol. ether. Yields a dye with diazo-benzene sulphonic acid.

*Ethylo-iodide*  $B'EtI$ . S. 6 at 15°; 2 at 100°. Formed by heating strychnine with alcohol and  $EtI$  at 100° (How, *A.* 92, 338). Four-sided prisms. Not attacked by  $KOHAq$ . Gives the strychnine reaction with  $K_2Cr_2O_7$  and  $H_2SO_4$ . Converted by moist silver oxide into the base  $B'EtOH$  2aq, which yields the salts  $B'EtNO_3$ ,  $B'EtPtCl_2$ ,  $B'EtHCO_3$ ,  $B'EtHCrO_4$  aq,  $B'EtCy$  [105°] (Claus a. Merck, *B.* 16, 2748), and  $B'EtI$ , (Jørgensen, *A. Ch.* [4] 11, 116).

*Isoamyl-chloride*  $B'C_5H_{11}Cl$  4aq. Formed by heating strychnine with isoamyl chloride (How, *Tr. E.* 21, 1, 27). Prisms. Yields  $B'C_5H_{11}OH$ ,  $B'C_5H_{11}I$ ,  $B'C_5H_{11}Br$ , crystallising in black prisms (Jørgensen, *J. pr.* [2] 3, 145), and  $B'EtHCrO_4$ .

*Bromo-ethylo-bromide*  $B'C_2H_5Br$ . Formed by heating strychnine with ethylene bromide and alcohol (Ménétrières, *J. pr.* 85, 230). White crystals, sl. sol. cold water and alcohol. Converted by  $AgNO_3$  into  $B'C_2H_5Br.NO_3$ , and by  $Ag_2SO_4$  into  $B'C_2H_5Br.SO_4H$ , whence baryta produces alkaline  $B'C_2H_5Br.OH$ .— $(B'C_2H_5Br)_2PtCl_2$ .— $B'C_2H_5Br_2$ : shining brown laminae.—Moist  $Ag_2O$  converts  $B'C_2H_5Br_2$  into  $B'C_2H_5OH$ , which is alkaline and is converted in aqueous solution by chlorine into  $C_{22}H_{21}Cl_3N_2O_4$ .— $B'C_2H_5CrO_4H$ .— $(B'C_2H_5Cl)_2PtCl_2$ .

*Chloro-ethylo-hydroxide*  $B'ClC_2H_5OH$ . Got by heating strychnine with glycolic chlorhydrin at 150° (Messel, *A.* 157, 7). Silky needles (containing aq). Yields  $(B'C_2H_5OH)_2SO_4$  2aq, which is converted by baryta into crystalline  $(B'C_2H_5OH)_2CO_2$  2aq.— $(B'C_2H_5OH)_2PtCl_2$ .

*Benzoyl-chloride*  $B'C_6H_5Cl$  [263°]. Prisms (containing aq). Yields  $(B'C_6H_5Cl)_2PtCl_2$ ,  $B'C_6H_5NO_3$  [c. 264°],  $(B'C_6H_5)_2Cr_2O_7$ , and  $B'C_6H_5SCy$  [237°] (Garzaroli, *M.* 10, 1).

*Benzoylo-hydroxide*  $B'C_6H_5OH$ . Plates.

*Chlorostrychnine*  $C_{22}H_{21}ClN_2O_4$  [ $\alpha_D$ ] = -105°. Formed, together with di- and tri-chloro-strychnine, by passing  $Cl$  into a solution of strychnine hydrochloride (Laurent, *A. Ch.* [3] 24, 312; *A.* 69, 14; Richet a. Bouchardat, *C. R.* 91, 990). Crystalline, v. sol. alcohol, ether, and chloroform. Chlorostrychnine forms a hydrate  $C_{22}H_{21}ClN_2O_4$  8aq on heating with alcoholic potash.— $B'_2H_2SO_4$  7aq.

**Dichloro-strychnine**  $C_{21}H_{20}Cl_2N_2O_2$ . Needles (from alcohol).

(a) **Tri-chloro-strychnine**  $C_{21}H_{17}Cl_3N_2O_2$ . Formed by saturating a solution of strychnine hydrochloride with  $Cl_2$ . Minute crystals (from alcohol). Yields a trihydrate which is not very poisonous.

(b) **Tri-chloro-strychnine**  $C_{21}H_{17}Cl_3N_2O_2$ . Formed by heating strychnine hydrochloride with  $PCl_5$  and chloroform (Stoehr, *J. pr.* [2] 42, 412; *B.* 20, 813). Microcrystalline powder (from alcohol). Gives the strychnine reaction with  $K_2Cr_2O_7$  and  $H_2SO_4$ .— $B'HCl$ : plates (from dilute alcohol).— $B'H_2SO_4$ : plates, m. sol. water.

**Bromo-strychnine**  $C_{21}H_{21}BrN_2O_2$ . [222°]. Formed by adding  $Br$  (2 at.) to a solution of strychnine hydrochloride (1 mpl.), ppg. by alkali, and recrystallising from alcohol (Shenstone, *C. J.* 47, 139; Beckurts, *B.* 18, 1236; Loebisch a. Schoop, *M.* 6, 855). Trimetric crystals;  $a:b:c = 1.459:1:1.195$  (Miers, *C. J.* 47, 144).— $B'HCl$ .— $B'HBr$ .— $B'HNO_3$ .— $B'H_2SO_4$ , 7aq.

**Methylo-iodide**  $B'MeI$ . Pearly plates, sol. alcohol. Converted by moist  $Ag_2O$  into  $B'MeOH_4aq$ .

**Dibromide**  $C_{21}H_{17}Br_2N_2O_2$ . Got by adding  $Br$  to a solution of strychnine at 40°. Bright yellow crystalline powder.

**Di-bromo-strychnine**  $C_{21}H_{17}Br_2N_2O_2$ . Got by adding  $Br$  to strychnine in chloroform. Trimetric crystals, v. sol. chloroform and dilute alcohol.— $B'HCl$ : needles.

**Nitro-strychnine**  $C_{21}H_{21}(NO_2)_2N_2O_2$ . [225°]. Formed by adding strychnine nitrate to  $H_2SO_4$  (Loebisch a. Schoop, *M.* 6, 845; 7, 59). Golden plates (from alcohol). Gives no colour with  $H_2SO_4$  and  $K_2Cr_2O_7$ . Dissolves in acids and alkalis. On heating with alcoholic potash it is converted into xanthostrychnol  $C_{21}H_{21}N_2O_4$ , which forms ruby-red crystals (containing 2aq) and gives salts with acids and bases.— $B'HCl$ .— $B'H_2PtCl_6$ .— $B'2KOH$ : red deliquescent needles.— $B'_2BaO.H_2O$ , 2aq.— $Ag_2C_{21}H_{21}N_2O_4$ : unstable pp.

(a) **Di-nitro-strychnine**  $C_{21}H_{20}(NO_2)_2N_2O_2$ . [226°]. Formed by passing nitrous acid gas into an alcoholic solution of strychnine nitrate (Claus a. Glassner, *B.* 14, 774). Orange-yellow plates. Converted by dilute  $HNO_3$  into cacostrychnine.— $B'HNO_3$ : yellow nodules (from acetone), v. sl. sol. hot water.

(b) **Tri-nitro-strychnine**. Formed by dissolving strychnine (60 g.) in fuming  $HNO_3$  (300 g.) at  $-10^\circ$  (Hanriot, *C. R.* 96, 585). Transparent amber-yellow prisms (from chloroform-alcohol), sol. hot water and alcohol, v. sol. chloroform. Decomposes at about 202°.— $B'HCl$ .—**Nitrates**: plates (from hot water).

**Amido-strychnine** v. vol. i. p. 184.

**Di-amido-strychnine**, *ibid.*

**Cacostrychnine** v. vol. i. p. 654.

**Deoxystrychnine**  $C_{21}H_{22}N_2O$  i.e.  $C_{20}H_{22}N \ll N^{\leftarrow} CO$  [172°]. Formed by boiling strychnine with  $HI$  and  $P$  (Tafel, *A.* 268, 245). Crystalline mass (containing 8aq), almost insol. water, sl. sol. ether and benzene, v. sol. alcohol. Melts, when hydrated, at 75°. Poisons like strychnine. Very bitter. Very little produces vomiting. Levorotatory, a 10 p.c. solution rotating  $1.6^\circ$  in a 100 mm. tube. Its solution in  $H_2SO_4$  is coloured bluish-violet by  $K_2Cr_2O_7$ , quickly becoming brown.

Its salts are more soluble than those of strychnine.— $B'HIaq$ . Groups of prisms.— $B'_2H_2Cr_2O_7$ . Thin yellow needles.— $B'_2H_2PtCl_6$ .

**Methylo-iodide**  $B'MeI$ . Crystals. S. c. 10 at 100°.

**Strychnine sulphonic acid**  $C_{21}H_{21}(SO_3H)N_2O_2$ . Formed by dissolving dry strychnine sulphate in fuming  $H_2SO_4$  (containing 30 p.c. anhydride extra) in the cold and allowing to stand a fortnight (Loebisch a. Schoop, *M.* 6, 857). Deliquescent mass. Does not give the strychnine reaction with  $K_2Cr_2O_7$  and  $H_2SO_4$ .

**Strychnine sulphonic acid**. Formed by heating strychnine with  $H_2SO_4$  (2 pts.) at 100° (Stoehr, *B.* 18, 3429; Guareschi, *G.* 17, 109). Amorphous powder, v. sl. sol. water and alcohol, sol. dilute acids and alkalis. Does not give a colour with  $K_2Cr_2O_7$  and  $H_2SO_4$ . Not poisonous.— $NH_4A'$ : v. sol. water, insol. alcohol.— $KA'$ : m. sol. water.— $BaA'$ : amorphous pp.

**Strychnine disulphonic acid**  $C_{21}H_{20}(SO_3H)_2N_2O_2$ . Got by heating strychnine with  $H_2SO_4$  and  $SO_3$  at 150°. Amorphous, v. sol. water, v. sl. sol. benzene, insol. alcohol and ether.— $NaA''$  6aq.— $BaA''$ : plates, sol. water.— $BaA''$  7aq.— $Ba(HA'')_2$ : yellow powder.

**STRYPHNIC ACID**  $C_{21}H_{21}N_2O_2$ . Got by adding  $HOAc$  to a mixture of uric acid and  $KNO_3$  and evaporating (Gibbs, *B.* 2, 841). Small pale-yellow crystals, sol. hot water. Sodium-amalgam forms crimson crystals.— $KA'$  1½aq: yellow needles.— $MgA'$  6aq.— $CaA'$  2aq.— $SrA'$  6aq.— $BaA'$  2aq.— $PbA'$ — $PbA'$  2aq.

**STYGERIC ACID** v. PHENYL-GLYCERIO ACID.

**STYGERIN**  $CHPh(OH).CH(OH).CH_2OH$ .

Formed by heating  $CHPhBr.CH_2Br.CH_2OH$  (v. DI-BROMO-PHENYL-PROPYL ALCOHOL) with 30 pts. water and some  $AgOAc$  at  $150^\circ$ – $165^\circ$  (Grimaux, *J.* 1873, 404). Yellow gummy mass with bitter taste. V. sol. Aq and alcohol, nearly insol. ether.

**STYPHNIC ACID** v. TRI-NITRO-RESORCIN.

**STRYACIN** v. Cinnamyl ether of CINNAMIO ACID.

**STYRENE**  $C_6H_5$  i.e.  $C_6H_5.CH=CH_2$ . *Styrol*. *Styrolene*. *Cinnamene*. *Phenyl-ethylene*. Mol. w. 104. (144°) (Schiff, *A.* 220, 93). S.G. 20° 9074.  $\mu_D = 1.541$  (Madan, *C. J. Proc.* 1, 107). S.V. 131 (Schiff).  $R_D$  58.1 (Nasini a. Bernheimer, *G.* 1, 93). Occurs in liquid storax (Bonastre, *J. Ph.* 17, 338; Simon, *A.* 31, 265; Blyth a. Hofmann, *A.* 52, 293, 325) and in coal tar (Berthelot, *A. Suppl.* 3, 368; Krämer a. Spilker, *B.* 23, 3282).

**Formation**.—1. By distilling cinnamic acid alone or with lime or baryta (Gerhardt a. Cahours, *A. Ch.* [3] 1, 96; Kopp, *C. R.* 53, 634; Howard, *C. J.* 13, 135; Kraemer, Spilker, a. Eberhardt, *B.* 23, 3269).—2. By distilling cupric cinnamate (Hempel, *A.* 59, 316).—3. By distilling balsam of Peru with pumice (Scharling, *A.* 117, 184).—4. By distilling dragon's blood alone or with zinc-dust (Glénard a. Bondault, *A.* 53, 325; Bötsch, *M.* 1, 610).—5. By heating acetylene at a dull-red heat (Berthelot, *C. R.* 62, 905, 947; *A.* 141, 181).—6. By passing ethylene alone or mixed with benzene or diphenyl through a red-hot tube (Berthelot, *Z.* [2] 4, 894; *A.* 142, 257; Barbier, *C. R.* 79, 660; Ferko, *B.* 20, 660).—7. By passing ethyl-benzene through a red-hot tube (Berthelot, *Z.* [2] 4, 589).—8. By heating  $C_6H_5.CH_2.CH_2Br$  alone or with alcoholic potash

at 180° (B.; Thorpe, *Z.* 1871, 130).—9. By heating  $C_6H_5CHBr.CH_3$  with alcoholic KOy (Radziszewski, *B.* 7, 140).—10. By distilling  $C_6H_5CH(OAc).CH_3$  (R.).—11. By heating  $C_6H_5CH(OH).CH_3$  (derived from acetophenone) with  $ZnCl_2$  (Emmerling & Engler, *B.* 4, 147).—12. By the action of acetylene on benzene in presence of  $AlCl_3$  (Varet & A. Vienne, *B.* [2] 47, 918; *C. R.* 104, 1375).—13. From phenyl-acetylene, zinc, and HOAc (Aronstein & Hollemann, *B.* 22, 1184).

**Properties.**—Oil, with aromatic odour. Inactive to light (Van't Hoff, *B.* [2] 25, 175). Miscible with alcohol and ether. Changes on keeping, or on heating in a sealed tube at 300°, to solid metastyrene. Combines with  $Cl_2$  and  $Br_2$ . HBr forms  $C_6H_5CHBr.CH_3$ . HCl forms  $PhCHCl.CH_3$  only (Sohramm, *B.* 26, 1709). Potash has no action. Fuming  $HNO_3$  forms nitro-styrene. Chromic acid mixture forms benzoic acid. Conc.  $H_2SO_4$  changes it to metastyrene. On heating with aqueous  $NaHSO_4$  at 120° styrene forms the compound  $C_6H_5NaHSO_4$  [306°] (W. von Miller, *N. R. P.* 24, 31). Condenses, in presence of  $H_2SO_4$  with toluene and xylene, forming diphenyl-propane and phenyl-tolyl-propane respectively (Kraemer & Spilker, *B.* 23, 3169).

**Metastyrene** ( $C_8H_8$ ). S.G. 1.054.  $\mu_D$  1.593 (Madan, *C. J. Proc.* 1, 107). Occurs in liquid storax (Kovalevsky, *A.* 120, 66). Formed from styrene on keeping or on heating in a sealed tube at 200°. Formed also by heating styrene with aqueous  $NaHSO_4$  at 110° (Miller, *A.* 189, 341). Transparent solid without taste or smell, becomes sticky when warmed. Highly refractive. Insol. water and alcohol, sl. sol. ether. Inactive to light (Van't Hoff, *B.* 9, 1339; cf. Berthelot, *C. R.* 85, 1191). Changes to styrene on distillation.  $Cl$  and  $Br$  act slowly, forming the same compounds as with styrene.

**Di-styrene**  $C_{16}H_{16}$ , i.e.  $Ph.CH:CH.CHMe.Ph$  (?). (o. 315° i.v.). S.G. 1.027;  $\mu_D$  1.016. V.D. 7.07 (calc. 7.2). Got by boiling cinnamic acid with  $H_2SO_4$  (1 vol.) and water (1½ vols.) (Erlenmeyer, *A.* 135, 122; Fittig & Erdmann, *A.* 216, 187). Liquid, with blue fluorescence, which slowly disappears. Inactive to light. If kept boiling for a long time it decomposes, forming toluene, styrene, high boiling products, and probably iso-propyl-benzene.

**Reactions.**—1. Chromic mixture gives benzoic acid.—2. Bromine gives the di-bromide  $C_{16}H_{16}Br_2$  [102°], crystallising from ether in needles. V. e. sol.  $CS_2$ , ether or benzene, v. sol. hot alcohol.

**Solid distyrene**  $C_{16}H_{16}$  [119°]. A product of the distillation of cinnamic acid or of its Ca salt (Engler & Leist, *B.* 6, 256; Miller, *A.* 189, 340). Formed also by passing  $C_6H_5C_6H_5Br_2$  over red-hot lime (Radziszewski, *B.* 6, 494). Tables. Yields a dibromide  $C_{16}H_{16}Br_2$  [238°], crystallising from benzene in needles (Liebermann, *B.* 22, 2256).

**References.**—AMIDO-, BROMO-, BROMO-AMIDO-, BROMO-NITRO-, CHLORO-, CHLORO-NITRO-, NITRO-, and NITRO-AMIDO-STYRENE.

**STYRENE DIBROMIDE v. DI-BROMO-ETHYL-BENZENE.**

**STYRENE DICARBOXYLIC ACID**  $C_{10}H_8O_4$ , i.e.  $[1:2]CO_2H.O_2C.CH:CH.CO_2H$ . *o*-Carboxy-cinnamic acid. [175°]. Formed by heating the salts of oxy-carboxy-phenyl-propionic acid (Gabriel

& Michael, *B.* 10, 1558, 2200). Slender needles (from water). Changed on fusion into the lactone of oxy-carboxy-phenyl-propionic acid.—PbA".—AgA": sticky pp.

**Isomeride v. p-CARBOXY-CINNAMIC ACID**, vol. ii. p. 190.

**STYRENE DICHLORIDE v. *o*-DI-CHLORO-DI-ETHYL-BENZENE.**

**STYRENE DI-IODIDE v. DI-iodo-ETHYL-BENZENE.**

**STYRENE DISULPHOCYANIDE**  $C_8H_6(SCN)_2$  [102°]. Formed by heating  $C_6H_5CHBr.CH_3$  with potassium sulphocyanide in alcohol (Nagel, *A.* 216, 323). Pale-yellow needles, v. sol. ether, hot benzene, and toluene. Crystallises from benzene as  $C_{10}H_8S_2N_2C_2H_4$  [62°]. Alcoholic ammonium sulphide at 100° forms  $(C_6H_5)_2S$  [151°]. Cold fuming  $HNO_3$  gives rise to the compound  $[1:4]C_6H_4(NO_2).CH(SCy)CH_3$  [112°] crystallising from alcohol in needles.

**DI-STYRENIC ACID**  $C_{16}H_{16}O_4$ , i.e.  $Ph.CH:CH.CPhH.CH_2.CO_2H$  or  $Ph.CH:CH.CH(CO_2H).CH_2Ph$ . Formed by boiling cinnamic acid with  $H_2SO_4$  (1 vol.) diluted with water (1 vol.) (Fittig & Erdmann, *A.* 216, 182). White amorphous powder. V. sl. sol. water, v. e. sol. ether, alcohol, or glacial acetic acid. It melts below 50°. May be distilled almost undecomposed.

**Reactions.**—1. Sodium amalgam has no action.—2. Br in  $CS_2$  forms no bromide.—3. Boiling  $H_2SO_4$  (1 vol.) mixed with water (1½ vols.) does not affect it.—4. Chromic mixture gives only benzoic acid.

**Salts.**— $Ca(C_{16}H_{16}O_4)_2$ .—BaA".—AgA'.

**Ether.**—EtA'. Liquid.

**STYROGALLOL**  $C_{10}H_8O$ , i.e.

$C_6H_5 \begin{matrix} \diagup CO \\ \diagdown CO \end{matrix} C_6H_5(OH)_2$ . Formed from cinnamic acid, gallic acid, and conc.  $H_2SO_4$  at 50° (Jacobsen & Julius, *B.* 20, 2583; von Kostanecki, *B.* 20, 3137). Yellow needles, which may be sublimed; sl. sol. hot alcohol. Not melted at 350°. With mordants it dyes like nitro-alizarin.

**STYROLENE ALCOHOL v. DI-OXY-ETHYL-BENZENE.**

**STYRONE v. CINNAMYL ALCOHOL.**

**STYRENE DIBROMIDE v. (4)-BROMO-PHENYL-PROPYL ALCOHOL.**

**STYRYL-ACRYLIC ACID v. PHENYL-PENTENOIC ACID.**

**STYRYL AMYL KETONE CARBOXYLIC ETHER**  $C_{17}H_{20}O_3$ , i.e.  $C_6H_5CH:CH.CO_2C_4H_9$  [102°]. Formed from di-ethyl-acetoacetic ether, benzoic aldehyde, and HCl in the cold (Claisen & Matthews, *A.* 218, 184). Triclinic prisms (from ligroin). Yields  $C_{17}H_{22}Br_2O_3$  [55°] crystallising in small prisms.

**STYRYL-ANGELIC ACID**  $C_{15}H_{14}O_4$ , i.e.  $C_6H_5CH:CH.CH(CO_2H).CO_2H$  [127°]. Formed by heating cinnamic aldehyde with butyric anhydride and sodium butyrate at 165° (Perkin, *C. J.* 81, 418). Crystals, v. sol. alcohol.—AgA'.

**STYRYL BUTENYL KETONE**  $C_{11}H_{14}O$ , i.e.  $C_6H_5CH:CH.CO.OH.CMe_2$  [179° at 14 mm.]. Formed by passing HCl into a mixture of benzoic aldehyde and mesityl oxide (Claisen & Claparède, *B.* 14, 851). Yellowish liquid, smelling like strawberries. Yields  $C_{15}H_{18}Br_2O$  [180°],

**STYRYL-CROTONIC ACID**  $C_9H_8O_2$ . [158°]. Formed by heating cinnamic aldehyde with propionic anhydride and sodium propionate (Perkin, C. J. 31, 413). Prisms (from ligroin). —AgA': white pp., sl. sol. cold water.

**STYRYL ETHYL KETONE CARBOXYLIC ACID**  $C_9H_8CH:CH.CO.CH_2CH_2.CO.H$ . *Cinnamoyl-propionic acid. Benzylidene-levulic acid.* [120°]. Formed from  $\beta$ -acetyl-propionic acid, benzoic aldehyde, and dilute KOHAq (Erdmann, A. 258, 130). Leaflets (from water). May be reduced to  $C_9H_8CH_2CH_2.CO.CH_2CH_2.CO.H$  [88°].

*Oxim*  $C_9H_8N.O$ . [149°].

**STYRYL ETHYL OXIDE**  $C_9H_8O$  i.e.  $C_9H_8CH:CH.O.C_2H_5$ . (217°). S.G. 2-981. Formed from  $\alpha$ -chloro-styrene and NaOEt at 180° (Erlenmeyer, B. 14, 1898). Aromatic liquid. Converted by heating with water into alcohol and phenyl-acetic aldehyde.

**STYRYL-ETHYL-PYRIDINE**  $C_{11}H_{11}N$

i.e.  $C_6H_5CH:CH.C \begin{smallmatrix} N.CH \\ CH:CH \end{smallmatrix} > C.Et$ . *Ethyl-stilbazole.* [58°]. (356° cor.). Formed by heating methyl-ethyl-pyridine with benzoic aldehyde and  $ZnCl_2$  at 220° (Plath, B. 21, 3087). Needles or plates, insol. water, v. sol. alcohol and ether, sl. sol. ligroin. Bromine yields the dibromide  $C_6H_5CHBr.CHBBr.C_2H_5EtN$ . [128°]. —B'HCl. [193°]. —B'H<sub>2</sub>PtCl<sub>2</sub> 2aq. [188°]. Needles. —B'HAuCl<sub>4</sub>. [168°]. —B'HSnCl<sub>3</sub> 3aq. [246°]. —B'HHgCl<sub>2</sub>. [196°]. —B'C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>. [203°].

**STYRYL-GLYOXAL**. *Oxim*  $C_9H_8N.O$  i.e.  $C_6H_5CH:CH.CO.CH:N.OH$ . [144°]. Formed from nitroso-acetone, benzoic aldehyde, and alcoholic NaOEt (Claisen a. Manasse, B. 22, 529). Crystals (from water or benzene). Gradually decomposes, with evolution of HCl.

**STYRYL-GLYOXYLIC ACID**  $C_9H_8O_3$  i.e.  $C_6H_5CH:CH.CO.CO.H$ . Formed by saponification of its amide by conc. HClAq, and also by saturating a mixture of benzoic aldehyde and pyruvic acid with HCl (Claisen, B. 13, 2124; 14, 2472). Gummy mass, sol. water. Split up by alkalis, even in the cold, into benzoic aldehyde and pyruvic acid. —AgA': pp.

*Amide*  $CHPh.CH.CO.CO.NH_2$ . [130°]. Prepared by the action of conc. HClAq and HOAc on the nitrile of cinnamic acid. Flat prisms or plates. Sol. ether and hot water.

*Reference.* —NITRO-STYRYL-GLYOXYLIC ACID.

**STYRYL-HYDANTOIC ACID**  $C_{11}H_{12}N_2O_3$ . [185°]. Formed by boiling styryl-hydantoin with baryta water (Pinner a. Spilker, B. 22, 692). White plates, sol. alcohol and hot water. Boiling HClAq converts it into styryl-hydantoin. —AgA'.

**STYRYL-HYDANTOIN** v. DI-OXY-STYRYL-METHAZOLE.

**STYRYLIDENE-THIO-GLYCOLLIC ACID** v. CINNAMYLIDENE-THIO-GLYCOLLIC ACID.

**DI-STYRYL-KETONE** v. DI-BENZYLIDENE-ACETONE and NITRO- and OXY-DI-STYRYL-KETONE.

**STYRYL-DI-METHYL-GLYOXALINE**

$C_{11}H_{11}N$ , i.e.  $C_6H_5CH:CH.C \begin{smallmatrix} NH.CMe \\ N-CMe \end{smallmatrix}$  [202°]. Formed from di-methyl di-ketone, cinnamic aldehyde, and alcoholic ammonia at 100° (Wadsworth, C. J. 57, 11). Crystals, v. sol. alcohol. —B'H<sub>2</sub>PtCl<sub>2</sub>: minute yellow needles.

**STYRYL METHYL KETONE** v. BENZYLIDENE-ACETONE and NITRO- and OXY-STYRYL METHYL KETONE.

**STYRYL METHYL KETONE CARBOXYLIC ETHER** v. BENZYLIDENE-ACETOACETIC ETHER, vol. i. p. 24.

**STYRYL-METHYL-OXAZOLE DIHYDRIDE**

$C_6H_5CH:CH.C \begin{smallmatrix} O.CHMe \\ N.CH_2 \end{smallmatrix}$ . [81°]. Formed from  $\beta$ -bromo-propylamine hydrobromide, cinnamoyl chloride, and alcoholic potash (Elfeldt, B. 21, 3226). Transparent crystals. —B'H<sub>2</sub>PtCl<sub>2</sub>. [198°]. —B'C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>. [183°]. Needles.

**STYRYL-METHYL-PYRIDINE**  $C_{11}H_{11}N$  i.e.  $C_6H_5CH:CH.C_2H_5MeN$ . *Methyl-stilbazole.* (c. 323°). S.G. 2-10717. Formed by heating benzoic aldehyde with ( $\alpha$ )-di-methyl-pyridine and  $ZnCl_2$  at 215° (Bachér, B. 21, 3072). Oil, v. sol. alcohol and ether. Gives  $C_{11}H_{11}Br.N$ . [140°]. May be reduced to  $C_{11}H_{11}N$  (c. 293°) and  $C_{11}H_{11}N$  (c. 288°). —Hydriodide. [211°]. —B'H<sub>2</sub>PtCl<sub>2</sub> 6aq. [183°]. —B'HAuCl<sub>4</sub>. [142°]. —B'HHgCl<sub>2</sub>. —B'C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>. [193°]. Yellow needles.

**STYRYL-DI-METHYL-PYRIDINE DICARBOXYLIC ACID**  $C_{11}H_{11}NO_4$

i.e.  $C_6H_5CH:CH.C \begin{smallmatrix} C(CO_2H).CMe \\ C(CO_2H).CMe \end{smallmatrix} > N$ . [241°].

Formed from its ether, which is got by the action of nitrous acid gas on an alcoholic solution of the dihydride  $C_{11}H_{11}NO$ , [149°], obtained from cinnamic aldehyde, acetoacetic ether, and alcoholic  $NH_3$  (Epstein, A. 231, 1). Minute colourless tablets (containing 2aq), sl. sol. water, sol. alcohol. Melts at 219° when hydrated. Converted by hypochlorous acid into  $C_{11}H_{11}NO_2$  2aq (Messinger, B. 19, 196). —K<sub>2</sub>A" 3aq. —(H<sub>2</sub>A")<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub>. —H<sub>2</sub>A" HCl. Decomposed by water.

*Ethyl ether* Et<sub>2</sub>A". [39°]. Yields the salt (Et<sub>2</sub>A")<sub>2</sub>H<sub>2</sub>PtCl<sub>4</sub> [195°].

**STYRYL-METHYL-THIO-GLYCOLLIC ACID** v. CINNAMYL-THIO-GLYCOLLIC ACID.

**STYRYL-( $\alpha$ )-NAPHTHOQUINOLINE**

$C_{21}H_{15}N$  i.e.  $C_6H_5CH:CH.C \begin{smallmatrix} CH:CH:CHPh \\ C.N \end{smallmatrix}$  [104°].

Formed by distilling the carboxylic acid  $C_{21}H_{15}N \begin{smallmatrix} C(CO_2H):CH \\ N \end{smallmatrix} > C.OH:CHPh$  [256°], which is got by the action of ( $\alpha$ )-naphthylamine on cinnamic aldehyde and pyruvic acid (Döbner a. Peters, B. 23, 1233). Concentric groups of yellowish needles, sl. sol. alcohol. —B'H<sub>2</sub>PtCl<sub>2</sub> 2aq. orange-yellow pp. —B'H<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>. —B'C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>. [230°]. Golden needles.

*Carboxylic acid*  $C_{21}H_{15}NO_4$ . [256°]. Yields BaA' 2aq, CuA' aq, and AgA'.

*Styryl-( $\beta$ )-naphthoquinoline*

$C_6H_5CH:CH.C \begin{smallmatrix} CH:CH \\ C.CH:CHPh \end{smallmatrix}$  [175°].

Formed in like manner from ( $\beta$ )-naphthylamine. White silky needles or pearly plates. —Salts: B'H<sub>2</sub>PtCl<sub>2</sub> 2aq. —B'H<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>. —B'C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>. [254°]. Golden needles, sl. sol. ether.

*Carboxylic acid*  $C_{21}H_{15}NO_4$ . [305°]. Lemon-yellow needles, sl. sol. hot alcohol.

**STYRYL-OXAZOLE DIHYDRIDE**  $C_{11}H_{11}NO$

i.e.  $C_6H_5CH:CH.C \begin{smallmatrix} O.CH_2 \\ N.CH_2 \end{smallmatrix}$ . [58°]. Formed from  $CH_2Br.CH_2NH.CO.CH:CHPh$  and alcoholic potash (Elfeldt, B. 24, 3226). —B'H<sub>2</sub>PtCl<sub>2</sub>. [194°]. Orange-yellow powder. —B'C<sub>6</sub>H<sub>5</sub>N<sub>3</sub>O<sub>7</sub>. [189°]. Yellow needles.

## STYRYL-PENTOXAZOLE DIHYDRIDE

$C_6H_5CH:CH.O \begin{smallmatrix} O.CH \\ N.CH \end{smallmatrix} CH_2$  [56°]. Formed by the action of alcoholic potash on the  $\gamma$ -bromopropyl-amide of cinnamic acid (Elfeldt, *B.* 24, 3227). Needles.— $B'H.PtCl_4$ . Decomposes at 193°.— $B'C_6H_5N.O_2$ . [196°].

## STYRYL-PHENOL o. OXY-DI-PHENYL-ETHYLENE.

(a). STYRYL-PYRIDINE  $C_{11}H_{11}N$  i.e.

$C_6H_5CH:CH.O \begin{smallmatrix} CH.CH \\ N.CH \end{smallmatrix} CH_2$  Stilbazole. [91°]. (325° cor.). Formed by heating benzoic aldehyde with methyl-pyridine and  $ZnCl_2$  at 220° (Baurath, *B.* 20, 2719; 21, 818). Crystals, m. sol. alcohol.

Reactions.—1. Br forms  $C_{11}H_{11}Br_2N$  [167°]. 2.  $HIAg$  reduces it to  $C_{11}H_{11}N$  [—3°].—3. Na and  $HOEt$  reduce it to  $C_{11}H_{11}N$  (288° cor.).

Salts.— $B'HCl$  4aq: needles. Melts at 177° when anhydrous.— $B'H_2PtCl_4$  2aq. [188°]. Red needles.— $B'HAuCl_4$ . [185°]. —  $B'HHgCl_2$  aq. [183°].— $B'HI$ . [159°]. Prisms, with blue reflex.

Reference.—OXY-STYRYL-PYRIDINE.

(Py. 3). STYRYL-QUINOLINE  $C_{11}H_{11}N$  i.e.

$C_6H_5 \begin{smallmatrix} CH:CH \\ N:C.CH:CHPh \end{smallmatrix}$  [100°]. Formed by distilling its carboxylic acid (Doebner a. Peters, *B.* 22, 3008). Got also by heating (Py. 3). methyl-quinoline with benzoic aldehyde and  $ZnCl_2$  (Wallach, *B.* 16, 2008; Jacobsen a. Reimer, *B.* 16, 2606). Crystals. Yields  $C_{11}H_{11}Br_2N$  [174°].—Salts:  $B'H_2PtCl_4$  2aq.— $B'HCr_2O_7$  2½aq.

References.—NITRO- and OXY-STYRYL-QUINOLINE.

## STYRYL-QUINOLINE CARBOXYLIC ACID

$C_6H_5 \begin{smallmatrix} C(CO_2H):CH \\ N \end{smallmatrix} \begin{smallmatrix} C.CH:CHPh \\ C.CH:CHPh \end{smallmatrix}$  [295°]. Formed from cinnamic aldehyde, pyruvic acid, and aniline in alcohol (Doebner a. Peters, *B.* 22, 3006). Yellow needles, insol. water, sl. sol. ether.— $MgA_2$ : concentric groups of needles.

## STYRYL-QUINOLINE SULPHONIC ACID

$C_6H_5(80.H)N.CH:CHPh$ . Formed by heating (Py. 1). methyl-quinoline (B. 2). sulphonic acid with benzoic aldehyde and  $ZnCl_2$  for six hours at 170° (Busch a. Koenigs, *B.* 23, 2682). Crystals (containing 2aq). V. sol. 50 p.c. acetic acid.

STYRYL THIENYL KETONE  $C_{11}H_{11}SO$  i.e.

$C_6H_5CH:CH.CO.C_6H_5S$ . [80°]. Formed by passing  $HCl$  into a mixture of thienyl methyl ketone and benzoic aldehyde (Brunswig, *B.* 19, 2895). Needles. Yields a dibromide  $C_{11}H_{11}Br_2SO$  [157°] crystallising from alcohol in plates.

## DI-STYRYL-DI-VINYL KETONE o. DI-PHENYL-DI-BUTYNYL KETONE.

## STYRYL-VINYL METHYL KETONE o.

## PHENYL-BUTYNYL METHYL KETONE.

SUBERIC ACID  $C_6H_4(CO_2H)_2$ . Formed in small quantity by the action of alcoholic potash on di-bromo-suberic acid (Hell a. Rempell, *B.* 18, 820). White powder, yielding at 225°—230° a sublimate of slender white needles.— $BaA''$ .— $CaA''$ .— $MgA''$  2aq.— $Ag_2A''$ : white pp. SUBERCONIC ACID. [165°—170°]. A crystalline product of the action of alcoholic potash on bromo-suberic acid (Ganttner a. Hell, *B.* 15, 149).

SUBERENE CARBOXYLIC ACID  $C_6H_9O_4$  [54°]. Formed by boiling chloro-suberonic acid

$C_6H_9ClO_4$  with  $NaOHAq$  (Spiegel, *A.* 211, 119). Pearly plates, volatile with steam. Reduced by sodium-amalgam to suberane carboxylic acid  $C_6H_9O_4$ .

SUBERIC ACID  $C_6H_8O_4$ . Mol. w. 174. [140°]. (c. 800°). (279° at 100 mm.) (Krafft, *B.* 22, 816). S. 142 at 15°. S. (ether) 8 at 15°. H.C.p. 992,409 (Lougouine, *C. R.* 107, 597); 985,600 (Stohmann, *J. pr.* [2] 40, 215). H.F. 249,400 (S.).

Formation.—1. By the action of nitric acid upon cork (Brugnatelli, *Crell. Ann.* 1787, i. 145; Bouillon-Lagrange, *A. Ch.* 23, 2; *J. Ph.* 8, 107; Chevreul, *A. Ch.* 62, 823; 96, 182; Brandes, *S.* 32, 393; 33, 83; 36, 263; *A.* 9, 295; Bussy, *J. Ph.* 8, 107; 19, 425; Boussingault, *J. pr.* 7, 211; Harff, *N. Br. Arch.* 5, 303).—2. By the action of nitric acid upon oleic and stearic acids (Laurent, *A. Ch.* [2] 66, 157; Bromels, *A.* 35, 89), upon castor oil (Tilley, *A.* 39, 166; Dale, *A.* 132, 244; 199, 145; Grote, *A.* 130, 208), upon linseed oil (Sacco, *A.* 51, 222), upon cocoa-nut oil (Wirtz, *A.* 104, 261), upon almond oil, upon spermaceti (Arppe, *A.* 120, 292; 124, 89), upon palmitic acid (Schröder, *A.* 148, 33), upon paraffin (Pouchet, *C. R.* 79, 320), upon palm oil (Ganttner a. Hell, *B.* 13, 1165; 14, 1549), and upon myristic acid (Noerdlinger, *B.* 19, 1896).—3. Occurs among the products of the distillation of crude fatty acids in superheated steam (Cahours, *C. R.* 94, 610).—4. From di-oxy-stearic acid and alkaline  $KMnO_4$  (Spiridonoff, *J. pr.* [2] 40, 250).—5. Suberic ether is formed by the electrolysis of  $CO_2Et.CH_2.CH_2.CO_2K$ , the yield being 28 p.c. of the theoretical amount (Crum Brown a. Walker, *A.* 261, 120).

Properties.—Long needles (from water) or tables. May be sublimed in needles. Not volatile with steam.

Reactions.—1. Yields hexane when distilled with baryta.—2. Forms suberone on distilling with lime.—3. Bromine at 160° forms bromo- and di-bromo-suberic acids, which when boiled with potash yield oxy- and di-oxy-suberic acids (Gal a. Gay-Lussac, *C. R.* 70, 1175).

Salts.— $K_2A''$ . S. 85 at 14°.— $Na_2A''$  ½aq. S. (of  $Na_2A''$ ) 50 at 14°.— $NaHA''$ .— $(NH_4)_2A''$ . S. 38 at 25°.— $BaA''$ : crystalline powder, less sol. hot water than cold. S. 2.2 at 7.5°; 1.8 at 100°.— $SrA''$ . S. 2.9 at 14°; 1.9 at 100°.— $CaA''$  aq. S. 62 at 14°; 42 at 100°.— $MgA''$  2aq. S. 13.5 at 20°.— $ZnA''$ . S. 0.41 at 14°.— $CuA''$  aq: blue pp.— $CuA''$  2aq. \* S. (of  $CuA''$ ) 0.24 at 16°.— $CdA''$  aq. S. (of  $CdA''$ ) 0.8 at 17°.— $HgA''$ . S. 0.12 at 7.5°.— $Al_2O_3A''$ . S. 0.094 at 6.5°.— $PbA''$ . S. 0.08 at 16°.— $Pb_2A''O_2$ .— $MnA''$  8aq. S. 1.08 at 13°.— $Fe_2A''O_3$ . S. 0.015 at 9°.— $CoA''$  4aq.— $CoA''$  2aq. S. (of  $CoA''$ ) 1.16 at 14°; 85 at 100°.— $NiA''$  4aq. S. (of  $NiA''$ ) 7.9 at 7.5°.— $Ag_2A''$ . S. 0.075 at 8°.

Methyl ether  $Me_2A''$ . S.G. 1.014.

Ethyl ether  $Et_2A''$ . (282°). S.G. 1.09852; 1.09783 (Perkin, *C. J.* 45, 517). M.M. 12.461 at 14°.

Amide  $C_6H_8N_2O_4$ . Crystalline.

Amic acid  $C_6H_8(CONH_2)_2.CO_2H$ . [c. 170°]. Formed by distilling ammonium suberate. Crystalline, v. sol. hot water.

Anilide  $C_6H_8(CO.NHPh)_2$ . [188°]. Formed by heating suberic acid (1 pt.) with aniline

(1 pt.) (Gerhardt & Laurent, *A. Ch.* [8] 24, 185). Fearly plates (from alcohol), v. sol. ether.

*Phenylamic acid*  $C_6H_5(CO.NHPh).CO_2H$ . Formed at the same time as the anilide. Minute laminae, sl. sol. hot water.—Agd': white pp.

*References*.—Bromo-, Chloro-, and Oxy-suberic acid.

*Isosuberic acid* is Di-ethyl-succinic acid (Hell, *B.* 22, 67).

**SUBERIC ALDEHYDE**  $C_8H_{14}O_3$ . (202°). A product of the action of fuming  $HNO_3$  on palmitic acid (Schröder, *A.* 143, 84). Oil, partially decomposed by distillation. Oxidised by bromine water to suberic acid.

**SUBEROCARBOXYLIC ACID** v. **HEXANE TRICARBOXYLIC ACID**.

**SUBEROMALIC ACID** v. **OXY-SUBERIC ACID**.

**SUBERONE**  $C_8H_{14}O$ . Mol. w. 112. (180° i.v.). V.D. 8.73 (calc. 8.89). Formed, together with hexane, by distilling suberic acid with lime (Boussingault, *A.* 19, 308; Tilley, *A.* 39, 167; Dale & Schorlemmer, *C. J.* 27, 935; *A.* 199, 147; Wislicenus, *A.* 275, 356). Colourless liquid, smelling like peppermint. Oxidised by  $HNO_3$  (S.G. 1.4) to *n*-pimelic acid [102°]. Does not reduce  $AgNO_3$  or Fehling's solution. Combines with bromine, forming a product which, when distilled over KOH, gives  $C_8H_{12}O$  (Ladenburg, *B.* 14, 2406). Combines with  $HCl$  yielding  $C_8H_{15}(OH)CN$ , which is converted by  $HCl$  into suberyl-glycollic acid  $C_8H_{15}(OH).CO_2H$  [80°], from which conc.  $HClAq$  at 130° produces chloro-suberane carboxylic acid  $C_8H_{12}Cl.CO_2H$ , a thick oil, converted by KOH into suberene carboxylic acid  $C_8H_{10}.CO_2H$  [54°], which may be reduced by sodium-amalgam to suberane carboxylic acid  $C_8H_{14}.CO_2H$ , and this may be oxidised by  $HNO_3$  to a dibasic acid  $C_8H_{12}O_4$  or  $C_8H_{10}O_4$  (Dale & Schorlemmer, *C. J.* 39, 589; Spiegel, *A.* 211, 117). Suberone is reduced in alcoholic solution by sodium to  $C_8H_{14}O$ , a colourless liquid, with mouldy smell (185°), S.G.  $\frac{1}{4}$ –9595, which unites with phenyl cyanate forming  $C_8H_{13}O.CO.NHPh$  [85°], and also with  $HI$  forming a compound which is converted by alcoholic potash into suberonylene  $C_8H_{12}$  [114–5°] and a little  $C_8H_{13}OEt$ . The compound  $C_8H_{14}O$  is reduced by conc.  $HIAq$  at 250° to  $C_8H_{12}$ . Suberonylene combines with bromine (Markownikoff, *C. R.* 110, 466).

*Osim*  $C_8H_{12}.NOH$ . Liquid, smelling like peppermint, sol. alcohol, ether, alkalis, and acids (Nägeli, *B.* 16, 497). Reduced by sodium-amalgam to  $C_8H_{14}.NH_2$ .

**SUBERO-TARTARIC ACID** v. **DI-OXY-SUBERIC ACID**.

**SUBERYL-GLYCOLIC ACID** v. **OXY-SUBERANIC ACID**.

**SUBLIMATION**. The passage of a solid body, when heated, to the state of vapour without melting. The temperature of sublimation is definite for every solid, and is dependent on the pressure. There is a definite pressure for each definite solid below which the substance cannot exist as a stable liquid, so that if heated below this pressure it passes from the solid directly to the gaseous state; but if heated under pressures greater than this pressure the substance first liquefies and then vaporises. As the definite pressure is considerably below that of the atmosphere for most substances, but few bodies

undergo sublimation, properly so called, when heated under ordinary conditions. Sublimation is treated fairly fully in Thorpe's *DICTIONARY OF APPLIED CHEMISTRY* (vol. iii. p. 609), and instances are given where the process is made use of in manufacturing operations. M. M. P. M.

**SUBSTITUTION**. The replacement of one element in a compound by another element is the primary meaning given to the term 'substitution.' As our ways of looking at composition, and changes of composition, are saturated with the conceptions of the molecular and atomic theory, substitution is better described as the replacement of an atom in a molecule by another atom. But the term must be widened to include cases wherein an atom is replaced by a group of atoms, which group is regarded in that reaction as if it were a single atom. The moment attention is paid to the number of atoms that can be substituted for some specified atom in a molecule the conception of chemical equivalency is found necessary to give a common foundation to the facts that are observed (v. *EQUIVALENCY*, vol. ii., especially pp. 449–451). The properties of a molecule are changed by the substitution of an atom or atomic group in the place of one, or more, of the atoms in the original molecule; the prosecution of the inquiry into the connections between the properties of molecules derived, by substitution, from some parent molecule leads to the hypothesis of types, which is afterwards merged in the wider subject of chemical classification (v. *CLASSIFICATION, CHEMICAL*, vol. ii. p. 196; *EQUIVALENCY*, vol. ii. pp. 450–451; *TYPES*, in this vol.).

Experiments show that the substitution of a more positive by a less positive atom, or atomic group, is accompanied by a change of properties in the direction that the substitution-product is more acidic than the parent substance. This field of inquiry has been cultivated systematically in recent years, and measurements have been made of the effects of substitution-changes of the kind indicated on the affinities of many acids. The results obtained have led, and are leading, to new conceptions of the nature of affinity, and of the constitutions of molecules (v. *PHYSICAL METHODS*, section *Electrical methods*, pp. 197–207 in this vol.).

M. M. P. M.

**SUCCINAMIDINE**  $C_8H_{11}N_3$ , i.e.

$CH_2(C(NH_2))_2NH$ . Formed by the action of ammonia on succinic-di-imido-di-ethyl ether  $C_4H_6(C(OEt):NH)_2$  (Pinner, *B.* 16, 362, 924, 1643, 1655). The salt  $B^{2+}HCl$  forms minute needles, dissolving in water with formation of  $NH_4Cl$  and succinimidine  $C_4H_7(NH)$ .

**SUCCINAMIDOXIM**  $C_4H_5(C(NH_2):NOH)_2$ .

*Succinens diamidoxim*. [188°]. Formed by adding hydroxylamine hydrochloride and  $Na_2CO_3$  to an alcoholic solution of the nitrile of succinic acid (Sembritzki, *B.* 22, 2958). Crystals, sol. hot water, sl. sol. hot alcohol, insol. ether. Coloured reddish-brown by  $FeCl_3$ . Fehling's solution gives a dirty green pp.  $Ac_2O$  forms  $C_4H_5(C(NH_2):NOAc)_2$  [168°].  $NaOEt$  and  $EtI$  form  $C_4H_5(C(NH_2):NOEt)_2$  [119°].  $BzCl$  and  $NaOH$  produce the benzoyl derivative  $C_4H_5(C(NH_2):NOBz)_2$  [192°], crystallising in needles, converted by heating with water at

159° into  $C_4H_5(C \begin{smallmatrix} \nearrow N \searrow O \end{smallmatrix} CPh)_2$ , [159°]. Aqueous potassium cyanate and HCl form  $C_4H_5(C(OH).NH.CO.NH)_2$ , [164°].

**Succinimidoxim**  $\begin{smallmatrix} CH_2.C \begin{smallmatrix} \nearrow N \searrow O \end{smallmatrix} \\ CH_2.C(OH) \end{smallmatrix} NH$ . Formed by heating the nitrile of succinic acid with hydroxylamine at 65° (Sembritzki, *B.* 22, 2964). Prisms (containing 2aq). Sol. hot water, insol. alcohol. Alcoholic NaOH forms a blue solution turning green.  $FeCl_3$  gives a dark-violet colour.— $Ag_2C_4H_5N_3O_2$ : pearly plates.

**Di-acetyl derivative**  $C_4H_5Ac_2N_3O_2$ , [171°]. Crystalline powder, sol. water.

**Di-benzoyl derivative**  $C_4H_5Bz_2N_3O_2$ , [189°]. Crystals, insol. water, sol. hot alcohol.

**SUCCINIC ACID**  $C_4H_4O_4$ , i.e.  $CO_2H.CH_2.CH_2.CO_2H$ . Mol. w. 118. [182°] (Krafft a. Noerdlinger, *B.* 22, 816; Reissert, *B.* 23, 2245); [185°] (Davidoff, *B.* 19, 406). (261°). S.G. 1.55. S. 2.68 at 0°; 5.14 at 14.5°; 12.1 at 100° (Bourgoin, *Bl.* [2] 21, 110; 29, 243; Miczynski, *M.* 7, 263). S. (alcohol) 7.5 at 15°. S. (ether) 1.25 at 15°. H.C.v. 357, 100. H.C.p. 356, 800. H.F. 226, 200 (Stohmann, *J. pr.* [2] 40, 207); 229, 000 (von Rechenberg). S.H. 290 (from 0°–60°); 365 (0°–150°) (Hess, *A. Ch.* [2] 35, 410). *Heat of Neutralisation*: Gal a. Werner, *C. R.* 103, 871.

**Occurrence**.—In amber (Agricola; Berzelius, *A. Ch.* 91, 187; Lecanu a. Serbat, *J. Ph.* 8, 511; 9, 89; Liebig a. Wöhler, *P.* 18, 162; D'Arcet, *P.* 86, 80), in turpentine from several species of pine, in *Chelidonium majus* (Walz, *N. J. P.* 15, 22; Zwenger, *A.* 114, 350), in lettuce (Köhnke, *B. J.* 25, 443), in *Papaver somniferum*, in unripe grapes (Brunner a. Brandenburg, *B.* 9, 982), in exudations from the bark of mulberry trees (Goldschmiedt, *M.* 3, 136), in beet juice (von Lippmann, *B.* 24, 3299), and in rhubarb (Brunner, *B.* 19, 595). Occurs also in the thymus gland of the calf, the spleen of the ox (Gorup-Besanez, *A.* 98, 28), in certain pathological exudations (Heintz, *A.* 76, 369; Brieger, *H.* 5, 368), in the urine of rabbits fed on carrots (Meissner a. Jolly, *J.* 1865, 675; cf. Salkowski, *Lf.* 4, 91), and in human urine after eating asparagus (Hilger, *A.* 171, 208).

**Formation**.—1. By the action of  $HNO_3$  on many organic substances, including fats, fatty acids from butyric acid upwards, wax, spermaceti, sebacic acid, and azelaic acid (Bromeis, *A.* 35, 90; 37, 232; Sthamer, *A.* 43, 346; Ronalds, *A.* 43, 356; Radcliff, *A.* 43, 351; Arppe, *A.* 95, 242; Dessaignes, *A.* 70, 102; 74, 361; Erlennmeyer, *B.* 7, 696; Noerdlinger, *B.* 19, 1895).—2. In the alcoholic fermentation of sugar (Pasteur, *Bl.* 1852, 52; *A.* 105, 264).—3. In the fermentation of asparagine (Piria, *A.* 68, 343), of calcium malate (Dessaignes; Liebig, *A.* 104, 363), of ammonium tartrate (König, *B.* 14, 211), and of flesh (Salkowski, *B.* 12, 649).—4. By reducing fumaric and maleic acids with sodium-amalgam (Kekulé, *A. Suppl.* 1, 133).—5. By reducing malic and tartaric acids with HI (R. Schmitt, *A.* 114, 106; Dessaignes, *A.* 115, 120; 117, 134).—6. By heating its nitrile (ethylene cyanide) with alcoholic potash at 100° (Maxwell Simpson, *A.* 118, 873), or by treating it with dilute nitric acid (Jungfleisch, *Bl.* [2] 19, 197).—7. From bromo-acetic acid and reduced silver at 180° (Steiner, *B.* 6,

184).—8. From  $\beta$ -chloro-propionic ether by successive treatment with KCy and potash (Wichelhaus, *Z.* [2] 8, 247).—9. From sodium acetoacetic ether by treatment with chloro-acetic ether and saponification of the product (Wipperrmann, *B.* 3, 337; Noeddecke, *A.* 149, 224).—10. By heating ethane tricarboxylic acid at 160° (Bischoff, *B.* 13, 2162).—11. By potash-fusion from gum arabic, milk sugar, and carminic acid (Hlasiwetz, *A.* 138, 76; 141, 840).—12. By reducing acetylene dicarboxylic acid with zinc and  $HIOAc$  at 60° (Aronstein a. Hollemann, *B.* 23, 1183).—13. Its ether is formed by electrolysis of  $CO_2Et.CH_2.CO_2K$  in aqueous solution; the yield being 60 p.c. of the theoretical (Crum Brown a. Walker, *A.* 261, 115).

**Preparation**.—1. By distilling amber, heating the watery distillate, filtering, and allowing to crystallise. The product is freed from oils by treatment with nitric acid.—2. By neutralising tartaric acid (2 kilos) with  $NH_4Aq$ , adding to the aqueous solution (40 litres)  $K_2HPO_4$  (20 g.),  $MgSO_4$  (10 g.) and a little  $CaCO_3$ . Fermentation is started by diluting a little (5 c.c.) of the solution with water (25 c.c.) and exposing it to the air for a few days. When fermentation has set in, the liquid is returned to the main quantity, and the whole kept at 25°–30° for seven weeks. The liquid is evaporated somewhat, clarified by white of egg, and boiled with lime. After cooling, the calcium succinate is collected and decomposed by  $H_2SO_4$ . The yield is good (500 g.) (Koenig, *B.* 15, 172).

**Properties**.—Monoclinic prisms, permanent in air, acid in taste. V. sol. water, m. sol. alcohol, sl. sol. ether. Resolved on boiling into water and anhydride; the lactone  $C_4H_4O_3$  being also formed.  $BaCl_2$  completely ppts. hot neutral solutions (Schmitt a. Hiepe, *Fr.* 21, 636).  $BaCl_2$  followed by  $NH_4Aq$  and alcohol ppts. succinic (but not benzoic) acid.  $FeCl_3$  gives in neutral solutions a reddish-brown pp.  $PbAc$ , gives a pp. sol. excess.

**Reactions**.—1. Not attacked by  $HNO_3$ ,  $CrO_3$ , or chlorine water.  $MnO_2$  and  $H_2SO_4$  yield acetic acid.  $KMnO_4$  in neutral solution oxidises it to oxalic acid and  $CO_2$ ; and, in acid solution, to  $CO_2$  (Berthelot, *Bl.* [2] 8, 390; Sorokin, *J. R.* 11, 383).—2. Yields ethylene and  $CO_2$  when decomposed in alkaline solution by an electric current (Kekulé, *A.* 131, 79; Bourgoin, *A. Ch.* [5] 20, 80; cf. Kolbe, *A.* 113, 244). In perfectly neutral solution only  $CO_2$ , CO, and O are given off at the positive pole.—3. *Potash-fusion* yields oxalic acid.—4.  $PCl_5$  forms successively: succinic anhydride  $C_4H_4(CO)_2O$ , succinyl chloride  $C_4H_3(COCl)_2$ , fumaryl chloride  $C_4H_2(COCl)_2$ , chloro-fumaryl chloride  $C_4HCl(COCl)_2$ , dichloro-maleyl chloride  $C_4Cl_2(COCl)_2$ , two tetrachlorinated di-chloro-maleyl chlorides, viz.:  $C_4Cl_2(CCl_2)_2(COCl)_2$  and  $C_4Cl_2(CCl_2)_2O$  (v. Di-chloro-maleic acid), and finally per-chloro-ethane,  $2C_2Cl_6$  (Kander, *J. pr.* [2] 31, 1).—5. On long boiling it yields the dilactone of diethyl ketone s-di-o-carboxylic acid  $\begin{smallmatrix} CO \quad O \\ \diagdown \quad \diagup \\ CH_2-CH_2-C-CH_2-CH_2 \end{smallmatrix}$  [75°]

(c. 203° at 15 mm.), crystallising from alcohol in plates, converted by  $HClAq$  into hydrochelicidonic acid  $CO(CH_2.CH_2.CO_2H)_2$ , [143°], which yields an oxim [129°] (Volhard, *A.* 253, 206).—6. Converted into succinic anhydride by treatment with

$P_2O_5$ ,  $AcCl$ ,  $BaCl$ ,  $Ac_2O$ , or succinyl chloride (Anschütz, B. 10, 825, 1881).—7. A solution containing 5 p.c. succinic acid and 1 p.c. uranium succinate when exposed to sunlight turns green and gradually gives off  $CO_2$ , leaving propionic acid in solution (Seekamp, A. 133, 253). Barium succinate (1 mol.) heated with  $NaOMe$  (1 mol.), for 8 hours at  $300^\circ$  yields propionic acid (Mai, B. 22, 2133).—8. Heated with a large excess of lime it yields ethane as chief product (Hanriot, *Bl.* [2] 45, 79).—9. The salts on distillation yield a liquid product ( $160^\circ$ – $250^\circ$ ) which yields benzene when distilled over zinc-dust (Von Richer, *J. pr.* [2] 20, 206; cf. Fumaro, G. 11, 273). Hydroquinone is also a product of the distillation of succinates.—10. The sodium salt heated with  $P_2S_5$  yields thiophene (Volhard a. Erdmann, B. 18, 464).—11. The Na salt heated with aldehydes and  $NaOAc$  forms oxyacids of the form  $R.CH(OH).CH(CO_2H).CH_2.CO_2H$  (Fittig, B. 18, 2523).—12. By heating with phthalic anhydride and  $NaOAc$  at  $250^\circ$ , exhausting the product with water and alcohol, and boiling the residue with aniline, there is got 'diphthalsuccinanilide'  $C_{12}H_{11}N_2O_2$  [267°] converted by boiling with  $HOAc$  and  $HCl$  into 'diphthalsuccindehydranilide'  $C_{10}H_9N_2O_2$ , crystallising from  $HOAc$  in small yellow prisms, not liquid at  $280^\circ$  (Roser, B. 18, 8122).—13. By heating with glycerin at  $200^\circ$  it yields 'succinin'  $C_8H_7(OH)A''$ , a gummy mass, insol. cold water, alcohol, and ether (Fumaro a. Danesi, G. 10, 58). Alkalis and acids split it up into glycerin and succinic acid.—14.  $\alpha$ -Chloropropionic ether and alcoholic potash give  $O_2H_2(CO.O.CHMe.CO.Et)$ , (c.  $302^\circ$  at 730 mm.) (Wurtz a. Friedel, A. *Ch.* [3] 63, 101; Wislicenus, A. 133, 262).

**Salts.**— $(NH_4)A''$ . Hexagonal prisms, v. sol. water and alcohol. Yields succinamide when heated.— $(NH_4)HA''$ . Triclinic crystals, v. sol. water and alcohol (Brooke, *Ann. Phil.* 22, 286). Formed by evaporating a solution of the neutral salt.— $K_2A''$  2aq. Deliquescent crystals, sol. alcohol, insol. ether.— $K_2A''$  3aq. Trimetric crystals (Salzer, B. 16, 3025).— $KHA''$  2aq. Efflorescent six-sided prisms.— $KHA''_x$ — $NaA''$  6aq: monoclinic prisms.— $NaHA''$ . Triclinic prisms.— $NaHA''$  8aq: monoclinic crystals.— $BaA''$ . Sl. sol. water, insol.  $NH_4Aq$  and alcohol. S.  $\cdot 42$  at  $6^\circ$ ;  $\cdot 43$  at  $12^\circ$ ;  $\cdot 28$  at  $67^\circ$  (Mieczynski).— $CaA''$  8aq: small needles, deposited gradually on mixing cold conc. solutions of sodium succinate and  $CaCl_2$ . On mixing the hot solutions  $CaA''$  aq is ppd. S. 1:1 at  $0^\circ$ ; 1:3 at  $24^\circ$ ;  $\cdot 8$  at  $68^\circ$  (Mieczynski, M. 7, 266).— $CaHA''$  2aq.— $SrA''$ : monoclinic prisms.— $BeA''$  2aq (Atterberg, *Bl.* [2] 21, 162).— $Be(OH)A''$  2aq.— $MgA''$  6aq. Prisms (Fehling, A. 49, 154).— $MgKA''$ — $MgA''_xO$ , aq.— $CrA''$  aq: scarlet pp.— $CuA''$  (dried at  $200^\circ$ ).— $CuA'' \cdot 2NH_3$ — $CuA'' \cdot 4NH_3$  (Schiiff, A. 123, 45).— $Fe(OH)A''$ : brownish-red pp.— $NiA''$  4aq.— $MnA''$  4aq. Triclinic prisms (Handl, *Sitz. W.* 82, 254).— $PbA''$  (dried at  $100^\circ$ ). White powder, sl. sol. water, v. sol.  $KOHAq$  and  $HNO_3$ .— $Pb_2O_4A''$ : sticky pp., got by adding lead subacetate to sodium succinate.— $Pb_2O_4A''_x$  (dried at  $200^\circ$ ): white powder.— $ZnA''$  (dried at  $200^\circ$ ). Crystalline powder.— $ZnA'' \cdot 3NH_3$  (Lutschak, B. 5, 80).— $CdA''$ .— $(UO_2)A''$  aq.— $K(UO_2)A''$  4aq.— $Na(UO_2)A''$  4aq.— $AgA''$ . White amorphous pp.—Quinine salt  $(C_{20}H_{24}N_2O_2)_2H_2A''$  aq. Prisms.

S.  $\cdot 11$  at  $10^\circ$  (Hesse, A. 135, 331).—Cinchonine salt  $(C_{20}H_{24}N_2O_2)_2H_2A''$  aq. Thick crystals (Hesse, A. 122, 226).—Cinchonidine salt  $(C_{20}H_{24}N_2O_2)_2H_2A''$  6aq. Silky prisms. S.  $\cdot 4$  at  $10^\circ$  (Hesse, A. 135, 342).—Urea salt  $(CON_2H_4)_2H_2A''$ . Six-sided monoclinic prisms;  $a:b:c=1.483:1.1:365$ ;  $\beta=83^\circ 28'$  (Lischmidt, *Sitz. W.* 52, ii. 238).—Ethylene-diamine salt  $C_2H_4(NH_2)_2H_2A''$ . [182°]. Thick white prisms, v. sol. water, insol. ether (Mason, C. J. 55, 10).—Benzylamine salts  $(C_6H_5NH_2)_2H_2A''$ . [145°]. Thin plates, sol. alcohol (Werner, C. J. 55, 628).— $(C_6H_5NH_2)_2H_2A''$ . [117°]. Rectangular prisms (containing aq), v. sol. water.

**Methyl ether**  $MeA''$ . [19°]. (195° cor.). S.G.  $\frac{2}{3}$  1.209 (Emery, B. 22, 8185);  $\frac{1}{4}$  1.1261;  $\frac{2}{3}$  1.0383 (Perkin, C. J. 45, 516). M.M. G. 232 at  $18.2^\circ$ . S.V. 159.7 (Lossen, A. 254, 64). H.C. (solid) 703,600. H.C. (liquid) 708,500. H.F. (solid) 205,400 (Stohmann, *J. pr.* [2] 40, 353). Formed from succinic acid,  $MeOH$ , and gaseous  $HCl$  (Fehling, A. 49, 195). Formed also from succinyl chloride and  $NaOMe$  in ether, and from  $Ag_2A''$  and  $MeI$ . Crystalline, sol. alcohol.

**Methyl ethyl ether**  $MeEtA''$ . (208° cor.). C.G.  $\frac{2}{3}$  1.093. S.V. 184.6. Formed by the action of  $EtAgA''$  on  $MeI$  (Köhler, A. 221, 88). On saponification with baryta it yields  $H_2A''$ ,  $HMeA''$ , and  $HEtA''$  (Lossen a. Köhler, A. 262, 200).

**Mono-ethyl ether**  $HEtA''$ . Formed by boiling succinic anhydride with alcohol (Heintz, J. 1859, 280). Syrup, miscible with water, alcohol and ether.— $AgEtA''$ : amorphous, sl. sol. water.—The salt  $NaEtA''$  is converted by  $POCl_3$  into  $CO_2Et.C_2H_5.COCl$  ( $144^\circ$  at 90 mm.), which is split up by distillation into  $EtCl$  and succinic anhydride, and is converted by phenyl hydrazine into  $CO_2Et.C_2H_5.CO.NH.NHPh$  [107°], crystallising in white needles, itself converted into  $O(CO.C_2H_5.CO.N.H.Ph)$ , [137°] by successive treatment with  $HOH$  and  $HCl$  (Michaelis a. Hermans, B. 25, 2748). The salt  $NaEtA''$  is converted by  $\alpha$ -chloro-propionic ether into  $CO_2Et.C_2H_5.CO.CHMe.CO.Et$  ( $280^\circ$ ) S.G.  $\frac{2}{3}$  1.119, which is split up by boiling with baryta water into succinic and lactic acids (Wurtz a. Friedel, J. 1861, 378).

**Ethyl ether**  $EtA''$ . (216.5° cor.). S.G.  $\frac{1}{4}$  1.0465;  $\frac{2}{3}$  1.0383. M.M. 8.380 at  $17.8^\circ$  (Pärkin). S.V. 209.4. Formed by boiling succinic acid (20 pts.) with alcohol (3 pts.) and  $H_2SO_4$  (1 pt.) (Eghis, B. 6, 1178; cf. D'Arcet, A. *Ch.* [2] 58, 291). It is also produced by heating  $C_2H_5Br$  in alcohol with potassium succinate in sealed tubes (Davidoff, *Bl.* [2] 46, 818; 19, 406). Oil. Converted by  $Na$  into the dihydride of dioxyterephthalic ether. Not attacked by hydroxylamine (Jeaurenaud, B. 22, 1273). Succinic ether (40 g.) treated with cyanamide (20 g.) and an alcoholic solution of  $K$  (18 g.) for 5 hours with inverted condenser yields  $C_2H_5(CO.NKCy)$ , and  $C_2H_5(CO,KCy)(CO.NKCy)$ . These bodies may be converted by  $AgNO_3$  into  $Ag$  salts, which may be separated by  $HNO_3$ , in which silver 'succinocyanamate' dissolves, while silver 'succinyl-di-cyan-di-amide' is insoluble. The  $Ag$  salts may then be suspended in alcohol and decomposed by  $H_2S$  (Möller, *J. pr.* [2] 22, 214). Succinyl di-cyan-di-amide  $C_2H_5(CO.NHCy)_2$ , [105°] crystallises in monoclinic pyramids (containing 2aq), decomposed by warm water into succinic

acid and cyanamide. It may also be prepared by the action of  $\text{NaNH}_2\text{Cy}$  on succinyl chloride, and by warming  $\text{C}_2\text{H}_3(\text{CO})_2\text{NCy}$  with cyanamide. The salt  $\text{C}_2\text{H}_3(\text{CO}_2\text{NaAgO})_2$  crystallises in plates, sol.  $\text{NH}_4\text{Aq}$ .— $\text{Et}_2\text{A}''$   $5^\circ\text{TiCl}_4$  (Demarcay, *O. R.* 70, 1414).— $\text{Et}_2\text{A}''$   $2^\circ\text{TiCl}_4$ .— $\text{Et}_2\text{A}''$   $2^\circ\text{TiCl}_4$ .

**Ethyl propyl ether**  $\text{EtPrA}''$ . (231°). S.G. § 1-0387. S.V. 230-2 (Wiens, *A.* 253, 800). Yields, on saponification by baryta, salts of  $\text{EtHA}''$ ,  $\text{PrHA}''$ , and  $\text{H}_2\text{A}''$  (Lossen & Köhler, *A.* 262, 201).

**Ethyl butyl ether**  $\text{Et(C}_4\text{H}_9\text{)A}''$  (247°). S.G. § 1-0218. S.V. 255-9 (W.).

**Ethyl heptyl ether**  $\text{Et(C}_7\text{H}_{15}\text{)A}''$ . (201-4°). S.G. § 9850. S.V. 332-9 (W.).

**n-Propyl ether**  $\text{PrA}''$  (247-1°). (Wiens, *A.* 253, 800); (250-8°) (Perkin, *C. J.* 53, 561). S.G. § 1-0189 (W.);  $\frac{1}{4}$  1-0157;  $\frac{1}{16}$  1-0062;  $\frac{1}{32}$  9986 (P.). S.V. 257-8. Formed by passing  $\text{HCl}$  into succinic acid in propyl alcohol.

**Isopropyl ether**  $\text{PrA}''$ . (228°). S.G. § 1-009 (Silva, *A.* 154, 255).

**Propyl butyl ether**  $\text{Pr(C}_4\text{H}_9\text{)A}''$ . (258-7°). S.G. § 1-0106. S.V. 277-8 (Wiens, *A.* 253, 300).

**Isobutyl ether**  $(\text{PrCH}_3)_2\text{A}''$ . (265° cor.). S.G.  $\frac{1}{16}$  9737;  $\frac{1}{32}$  9667. M.M. 12-707 at 14-5° (Perkin, *C. J.* 45, 519).

**Isoamyl ether**  $(\text{C}_5\text{H}_{11})_2\text{A}''$ . (290° cor. at 728 mm.). S.G. 13-961. Formed from  $\text{Ag}_2\text{A}''$  and isoamyl bromide (Del Zanna & Guareschi, *Atti Real. Instit. Veneto* [5] 6; *B.* 12, 1699).

**Heptyl ether**  $(\text{C}_7\text{H}_{15})_2\text{A}''$  (350°). S.G. § 9519. S.V. 459-6 (Wiens).

**Cetyl ether**  $(\text{C}_{18}\text{H}_{37})_2\text{A}''$ . [58°]. Formed by heating the acid with cetyl alcohol (Tütschhoff, *Rep. Chim. pure*, 2, 463). Plates, sl. sol. alcohol, v. sol. ether.

**Ethylene ether**  $\text{C}_2\text{H}_4\text{A}''$ . [c. 90°]. By heating succinic acid with glycol at 170° there is formed crystalline  $(\text{CO}_2\text{H.C}_2\text{H}_4)_2\text{C}_2\text{H}_4$ , melting below 100°, which at 300° yields  $\text{C}_2\text{H}_4\text{A}''$  (Lourenço, *A.* 115, 358). Crystalline, insol. water and ether, sol. hot alcohol. Decomposed by distillation.

**Di-phenyl ether**  $\text{C}_6\text{H}_5(\text{CO}_2\text{Ph})_2$ . [119°]. (330°). Formed from succinic acid, phenol and  $\text{POCl}_3$  (Rasiński, *J. pr.* [2] 26, 63). Got also from succinyl chloride and phenol (Weselsky, *B.* 2, 519). Completely decomposed by slowly heating (Anschütz, *C. J.* 47, 898).  $\text{NaSEt}$  gives di-thio-succinic ether. Pearly plates (from alcohol).

**Di-benzyl ether**  $(\text{CH}_2\text{Ph})_2\text{A}''$ . [42°]. Formed from  $\text{Ag}_2\text{A}''$  and benzyl bromide (Zanna & Guareschi, *G.* 11, 256). Laminar.

**Chloride**  $\text{C}_2\text{H}_3(\text{CO}_2\text{Cl})_2$  or  $\text{C}_2\text{H}_3\text{<CO>O}$ .

Mol. w. 155. (190°-200°). S.G. 1-39. Formed from succinic anhydride and  $\text{PCl}_5$  (Gerhardt & Chiozza, *A.* 87, 293).

**Preparation**.—Succinic acid is heated with  $\text{PCl}_5$  for two days with an inverted condenser in an oil bath. The  $\text{POCl}_3$  is distilled off (below 120°) and the residue shaken with benzoline that has been dried over lime. The benzoline dissolves the rest of the  $\text{POCl}_3$ , and the succinyl chloride separates as a lower layer. The operation is repeated until the oil no longer forms phosphoric acid when mixed with water (H. Möller, *J. pr.* [2] 22, 208).

**Properties**.—Solidifies at 0°.

**Reactions**.—1. Reduced to butyrolactone by sodium amalgam (3 p.c. Na) acting upon its

ethereal solution mixed with glacial acetic acid.—2. Benzene and aluminium chloride give  $\text{C}_2\text{H}_3\text{<CPh}_2\text{>O}$  [90°].  $\text{C}_2\text{H}_3(\text{CO}_2\text{C}_6\text{H}_5)_2$  [184°],

and a little  $\beta$ -benzoyl-propionic acid (Auger, *A. Ch.* [6] 22, 312; *Bl.* [2] 49, 345).—3.  $\text{ZnEt}_2$

gives  $\text{C}_2\text{H}_3\text{<CCEt}_2\text{>O}$ .—4.  $\text{Na}_2\text{S}$  gives succinyl

sulphide.—5.  $\text{PCl}_5$  at 230° gives off  $\text{HCl}$  and the product, after treatment with water, contains  $\text{C}_2\text{Cl}_2\text{O}$  (199°-215°) which solidifies below 0°. Hot conc.  $\text{H}_2\text{SO}_4$  dissolves  $\text{C}_2\text{Cl}_2\text{O}$  and the product, diluted with water, yields on evaporation hygroscopic crystals, which on sublimation give non-hygroscopic plates of  $\text{C}_2\text{Cl}_2\text{O}_2$  [120°] (Kauder, *J. pr.* [2] 28, 191). Di-chloro-maleic chloride is also a product of the action of  $\text{PCl}_5$  on succinyl chloride.—6. Chlorine passed into boiling succinyl chloride forms chlorides of fumaric, chloro-fumaric, and di-chloro-maleic acids (Kauder, *J. pr.* [2] 31, 24).—7.  $\text{C}_2\text{H}_3\text{SO}_2\text{NBzAg}$  forms  $\text{C}_2\text{H}_3(\text{CO}_2\text{NBzSO}_2\text{C}_6\text{H}_5)_2$  [146°] (G. a. C.).—8. Phenyl-hydrazine forms the compound  $\text{C}_2\text{H}_3(\text{CO}_2\text{NH.NHPh})_2$  [218°] (Freund, *B.* 21, 2462; Fischer, *B.* 22, 2728), whence phosgene produces  $\text{C}_2\text{H}_3(\text{CO}_2\text{N}_2\text{PhCO})_2$  [225°]. Sodium phenyl

hydrazine in benzene forms  $\text{C}_2\text{H}_3\text{<CO.NH}$

[199°], which gives  $\text{C}_2\text{H}_3\text{<CO.NPh}$

[179°] (Michaelis & Hermans, *B.* 25, 2751).—9. Cyan-

amide in ethereal solution forms, on warming, succin-cyanamide  $\text{C}_2\text{H}_3(\text{CO}_2\text{NCy})_2$  [138°] crystal-

lising from alcohol in plates (Möller, *J. pr.* [2] 22, 207).—10. Cyano-acetic ether in  $\text{Et}_2\text{O}$  at 100°

forms  $\text{C}_2\text{H}_3\text{C}_2\text{O}_2\text{CCy.CO}_2\text{Et}$  [126°] (Müller, *C. R.* 112, 1140).—11. Urea at 65° forms the compound

$\text{C}_2\text{H}_3(\text{CO}_2\text{NH.CO}_2\text{NH})_2$ , a powder, v. sl. sol. hot

water (Conrad, *J. pr.* [2] 9, 301).

**Anhydride**  $\text{C}_2\text{H}_3\text{<CO>O}$ . Mol. w. 100.

[119°]. (261°) (Krafft & Noerdlinger, *B.* 22, 816).

**Formation**.—1. By rapidly boiling succinic acid.

2. By distilling the acid with  $\text{P}_2\text{O}_5$  (D'Arceet, *A. Ch.* [2] 58, 282), with  $\text{PCl}_5$  (Gerhardt &

Chiozza, *C. R.* 36, 1050), or with  $\text{BzCl}$  (Kraut, *A.* 137, 254).—3. By warming succinyl chloride

with dry oxalic acid (Anschütz, *A.* 226, 18).—4. By heating succinic acid (100 g.) with  $\text{POCl}_3$

(65 g.) at 120° (Volhard, *A.* 242, 150).—5. By

distilling succinyl chloride (180 g.) with succinic

acid (137 g.), and crystallising from alcohol

(H. Möller, *J. pr.* [2] 22, 194).—6. By the action

of dry  $\text{Pb}(\text{NO}_3)_2$  (also nitrates of other heavy

metals) upon succinyl chloride;  $\text{PbCl}_2$  is pro-

duced, and  $\text{N}_2\text{O}$ , and oxygen evolved; yield a

60 p.c. of theoretical (Lachowicz, *B.* 18, 2990).

**Properties**.—Long trimetric needles (from

alcohol);  $a:b:c = 595:1:463$  (Bodewig, *B.* 14,

2788). Sl. sol. water, v. sl. sol. ether. Converted

by dry  $\text{NH}_3$  into succinimide. Slowly converted

by boiling alcohol into succinic ether. Phenyl-

hydrazine reacts in alcoholic solution, forming

$\text{CO}_2\text{H.C}_2\text{H}_3\text{CO}_2\text{NH.NHPh}$  [120°], converted by

heat into  $\text{C}_2\text{H}_3\text{<CO>N.NHPh}$  [155°] (Auger,

*A. Ch.* [6] 22, 339; cf. this vol. p. 45) or [158°]

(Michaelis, *B.* 25, 2750). Potassium cyanamide

forms 'succinocyanamic' acid, the compound

$\text{CO}_2\text{H.C}_2\text{H}_3\text{CO}_2\text{NHCy}$  [128°], which is v. a. sol.

water, v. sol. alcohol and ether, is split up by

dilute acids into succinic acid and cyanamide, and yields the following six salts  $\text{Na}_2\text{A}$ ,  $\text{BaA}$ ,  $\text{CaA}$ ,  $\text{AgHA}$ , and  $\text{Ag}_2\text{A}$  (Möller, *J. pr.* [2] 22, 193). Urea heated with succinic anhydride at 125° forms succinic acid  $\text{CO}_2\text{H}_2\text{C}_4\text{H}_4\text{CO.NH.CO.NH}_2$  [205°] (Pike, *B.* 6, 1104).

**Nitrile**  $\text{C}_4\text{H}_4(\text{CN})_2$ . *Ethylene cyanide*. Mol. w. 80. [55°]. (147° at 10 mm.) (F); (185° at 60 mm.) (Biltz, *B.* 25, 2541). H.C.p. 546, 100. H.F. (from diamond) - 32,000 (Berthelot a. Petit, *C. R.* 108, 1217). Formed by boiling ethylene bromide (300 g.) with alcohol (500 g.) and KCy (200 g.) for two hours with inverted condenser (Maxwell Simpson, *Fr.* 10, 574; Geuther, *A.* 120, 268; Fauconnier, *Bl.* [2] 50, 214; Nevole a. Tscherniak, *C. R.* 86, 1411). Amorphous, sometimes crystalline, solid, v. sol. water, alcohol, and chloroform; sl. sol. ether. Decomposed by distillation under atmospheric pressure. Converted into succinic acid by boiling alcoholic potash. Aniline hydrochloride at 200° reacts, forming di-phenyl-succinimide  $\text{C}_6\text{H}_5\text{C}(\text{NH})\text{C}(\text{NPh})\text{NPh}$  (Blochmann, *B.* 20, 1856). —  $\text{C}_4\text{H}_4\text{Cy}_2\text{AgNO}_2$ : tables, sol. water and alcohol, insol. ether.

**Amide-nitrile**  $\text{CN.C}_4\text{H}_4\text{CO.NH}_2$ . Formed by heating the nitrile with alcoholic potash at 110° (Drouin, *C. R.* 103, 675). Crystals, sl. sol. alcohol, insol. ether. Slowly decomposes at 210°-220°.

**Amide**  $\text{C}_4\text{H}_4(\text{CO.NH}_2)_2$ . *Succinamide*. Mol. w. 116. [243°]. S. 625 at 9° (Henry, *C. R.* 100, 943); 11 at 100° (F.). Formed by the action of aqueous  $\text{NH}_3$  on the ether and on the chloride (D'Arcet, *A.* 16, 215; Fehling, *A.* 49, 196). Formed also by warming succinimide with alcoholic  $\text{NH}_3$  (Menschutkin, *A.* 162, 165, 187). Needles, insol. ether and alcohol. Decomposed at 200° into  $\text{NH}_3$  and succinimide or by saturating at -15° with gaseous  $\text{NH}_3$ , and heating to 150° in sealed tubes (Roubtsoff, *Bl.* [2] 45, 250). —  $\text{HgC}_4\text{H}_4\text{N}_2\text{O}_2$  1.5 aq. White powder, deposited on cooling from a solution of  $\text{HgO}$  in hot aqueous succinamide.

**Iso-amide**  $\text{C}_4\text{H}_4\text{C}(\text{CO.NH}_2)_2\text{O}$ . [c. 95°].

Formed to the extent of 8 p.c. in the preparation of the amide from succinyl chloride and  $\text{NH}_3$  aq (Auger, *A. Ch.* [6] 22, 312). Hygroscopic mass. Its aqueous solution gives with  $\text{AgNO}_3$  a pp. of  $\text{C}_4\text{H}_4(\text{CO})_2\text{NAg}$ .

**Methylamide**  $\text{C}_4\text{H}_4(\text{CO.NHMe})_2$ . [175°]. Plates (Wallach a. Kamenski, *B.* 14, 170).

**Dimethylamide**  $\text{C}_4\text{H}_4(\text{CO.NMe}_2)_2$ . [81°]. Formed from succinyl chloride and  $\text{NHMe}_2$  in ether (Franchimont, *R. T. C.* 4, 202). Crystals (from ether), v. sol. water.

**Benzyl-di-amide**  $\text{C}_4\text{H}_4(\text{CONH}_2)(\text{CONHCH}_2\text{Ph})$ . [189°]. Formed from the benzylimide and ammonia at 100° (Werner, *C. J.* 55, 633). Minute prisms, sl. sol. ether and hot benzene. Yields the benzylimide when heated.

**Di-benzyl-diamide**  $\text{C}_4\text{H}_4(\text{CO.NHCH}_2\text{Ph})_2$ . [206°]. Formed from succinic ether and benzylamine in alcohol. Thin plates, not decomposed by boiling  $\text{NaOHAq}$ .

**Anilide**  $\text{C}_4\text{H}_4(\text{CO.NHPh})_2$ . [227°]. Formed by boiling succinic acid with aniline (Laurent a.

Gerhardt, *A. Ch.* [3] 24, 179; *A.* 68, 27; Menschutkin, *A.* 162, 187). Needles (from alcohol), insol. water. Not affected by boiling alcoholic potash or by nitrous acid. Gives the phenylimide on distillation. Cold fuming  $\text{HNO}_3$  converts it into  $\text{C}_4\text{H}_4(\text{CO.NHC}_6\text{H}_5(\text{NO}_2)_2)_2$  [144°], [260°] (Hübner, *A.* 209, 877). Benzoic aldehyde at 180° forms succinic phenylimide and benzylidene-aniline (Schiff, *A.* 148, 338).

**Amide-anilide**  $\text{CO.NH}_2\text{C}_4\text{H}_4\text{CONHPh}$ . [181°]. Formed by heating the phenylimide with alcoholic  $\text{NH}_3$  at 100° (Menschutkin, *A.* 162, 182). Broad needles (from water), sl. sol. hot alcohol. Alkaline KOBz followed by heating with  $\text{HOAc}$  forms  $\text{C}_4\text{H}_4\text{C}_2\text{O}_2(\text{NHBz})(\text{NHPh})$  crystallising in minute needles, converted by boiling alcohol into  $\text{C}_4\text{H}_4\text{C}_2\text{O}_2(\text{NH}_2)(\text{NHC}_6\text{H}_5\text{Br})$  [215°], whence potash forms the compound  $\text{CO}_2\text{H}_2\text{C}_4\text{H}_4\text{CO.NHC}_6\text{H}_5\text{Br}$  [14] [187°] (Hoogewerf a. Van Dorp, *R. T. C.* 9, 41).

**Di-(a)-naphthyl-di-amide**  $\text{C}_4\text{H}_4(\text{CO.NHC}_6\text{H}_4)_2$ . [285°]. Needles (from  $\text{HOAc}$ ). Converted by fuming nitric acid into  $\text{C}_4\text{H}_4(\text{CO.NHC}_6\text{H}_4(\text{NO}_2)_2)_2$  [225°], and  $\text{C}_4\text{H}_4(\text{GO.NH.C}_6\text{H}_4(\text{NO}_2)_2)_2$  [256°].

**Tetra-phenyl-di-amide**  $\text{C}_4\text{H}_4(\text{CONPh})_2$ . [234°] (Piutti, *G.* 14, 467). Needles (from alcohol).

**o-Tolyl-diamide**  $\text{C}_4\text{H}_4(\text{CONH}_2)_2\text{CO.NHC}_6\text{H}_4$ . [160°]. Formed by heating the o-tolylimide with alcoholic  $\text{NH}_3$  at 100°. Plates.

**Di-o-tolyl-diamide**  $\text{C}_4\text{H}_4(\text{CO.NHC}_6\text{H}_4)_2$ . [100°]. White needles (Bechi, *B.* 12, 25, 321). V. sl. sol. water, m. sol. alcohol.

**p-Tolyl-di-amide**  $\text{C}_4\text{H}_4(\text{CONH}_2)_2\text{CO.NHC}_6\text{H}_4$ . [148°]. Formed by heating the p-tolylimide with alcoholic  $\text{NH}_3$ .

**Di-p-tolyl-diamide**  $\text{C}_4\text{H}_4(\text{CO.NHC}_6\text{H}_4)_2$ . [256°]. Plates (from alcohol), sl. sol. hot water (Bechi, *B.* 12, 323; Hübner, *A.* 209, 380). Yields on nitration  $\text{C}_4\text{H}_4(\text{CO.NHC}_6\text{H}_4(\text{NO}_2)_2)_2$  [217°] and  $\text{C}_4\text{H}_4(\text{CO.NH.C}_6\text{H}_4(\text{NO}_2)_2)_2$ .

**(β)-Naphthalide**  $\text{C}_4\text{H}_4(\text{CO.NHC}_6\text{H}_4)_2$ . [266°] (Bischoff a. Reebe, *B.* 25, 3267). Got by heating succinic acid (10 g.) with (β)-naphthylamine (24 g.). Insol. ordinary solvents, sol.  $\text{H}_2\text{SO}_4$ .

**Amic acid**  $\text{CO}_2\text{H}_2\text{C}_4\text{H}_4\text{CO.NH}_2$ . *Succinamic acid*. [157°]. Formed by warming succinimide with an equivalent quantity of baryta water (Teuchert, *A.* 134, 136) or milk of lime (Menschutkin, *A.* 162, 175). Formed also from nitrosoglutaric acid by heating alone or with  $\text{Ac}_2\text{O}$  (Serda a. Wiedemann, *B.* 23, 3294; Wolff, *A.* 260, 114). Needles, m. sol. water, insol. alcohol. Decomposed at 200° into water and succinimide. Boiling water forms acid ammonium succinate.

**Salts**. —  $\text{KA}'$ : very hygroscopic mass (Landsberg, *A.* 215, 201). —  $\text{BaA}'$ : needles, v. sol. water. —  $\text{CaA}'$ :  $\text{MgA}'$ , 8 aq: trimetric crystals. —  $\text{MgA}'$ , 6 aq. —  $\text{CdA}'$ , aq: prisms. —  $\text{CuA}'$ ,  $\text{PbA}'$ : Concentric needles, v. sol. water. —  $\text{MnA}'$ , 5 aq. —  $\text{ZnA}'$ . —  $\text{AgA}'$ : monoclinic crystals, v. sol.  $\text{NH}_3$  aq.

**Ethyl-amic acid**  $\text{CO}_2\text{H}_2\text{C}_4\text{H}_4\text{CONHET}$ . Formed by warming the ethylimide with baryta water (Menschutkin, *A.* 182, 92). —  $\text{EtA}'$ : crystals, v. sol. water.

**Ethylene-di-amic acid**  $C_4H_4N_2O_4$ , *ts.*  $C_4H_4(NH.CO.C_6H_4.CO.H)_2$ . **Ethylene-disuccinamic acid**. [185°]. Formed by boiling the diimide with baryta (Mason, *C. J.* 55, 18). Large plates, v. sol. hot water. Does not yield an oxim or a phenyl-hydrazide. —  $CaA'$  8aq; prisms. —  $Ag_2A''$ : white amorphous powder.

**Benzylamic acid**  $CO_2H.C_6H_4.CO.NH.C_6H_5$ . [139°]. Formed by boiling the benzyl-imide (2 mols.) with aqueous barium hydroxide (1 mol.) (Werner, *C. J.* 55, 631). Flat prisms, m. sol. hot water, v. sl. sol. ether.

**Phenylamic acid**  $CO_2H.C_6H_4.CO.NHPh$ . **Succinanilic acid**. [149°]. Formed by boiling the phenylimide with  $NH_4Aq$  (Laurent a. Gerhardt, *A. Ch.* [3] 24, 179) or baryta (Menschutkin, *A.* 162, 176). Flat needles, v. sl. sol. cold water. Decomposed by heat into water and the phenylimide. Boiling alcoholic HCl forms succinic acid. —  $CaA'_2$  4aq. —  $BaA'_2$  3aq. —  $AgA'$ : crystalline pp.

**o-Tolyl-amic acid**  $CO_2H.C_6H_3.CO.NH.C_6H_4$ . [97°]. Got by boiling the o-tolylimide with baryta water (Bechi, *B.* 12, 322). White needles. —  $BaA'_2$  4aq.

**p-Tolyl-amic acid** [157°]. —  $BaA'_2$  4aq.

**(a)-Naphthyl-amic acid**  $CO_2H.C_{10}H_7.CO.NH.C_{10}H_7$ . [171°]. Formed by heating the (a)-naphthylimide with  $KOH Aq$  (Pellizzari, *A.* 248, 158; *G.* 18, 323). Needles or plates (from alcohol), v. e. sol. HOAc and benzene.

**(β)-Naphthyl-amic acid** [192°]. Crystals. **Di-phenyl-amic acid**  $CO_2H.C_6H_4.CONHPh$ . [119°]. Plates (Piutti, *G.* 14, 468). —  $AgA'$ : pp.

**Phenylene-di-amic acid**  $C_6H_4(NH.CO.C_6H_4.CO.H)_2$ . Formed by heating phenylene-diamine with succinic acid at 200° (Biedermann, *B.* 9, 1668). Small crystals (from HOAc). Melts above 360°. Converted by  $KOHAq$  and MeI into  $C_6H_4(NMe_2.CO.CO.NH.CO.C_6H_4)$  crystallising in plates or tables (containing  $1\frac{1}{2}$  aq) (Griess, *B.* 18, 2410).

**Imide**  $\begin{smallmatrix} CH_2.CO \\ CH_2.CO \end{smallmatrix} > NH$ . [126°] (Erlenmeyer, *Z.* [2] 5, 175). (288°). H.C. 439,000. H.F. 110,500 (Berthelot a. André, *Bl.* [3] 4, 229). Formed from succinic anhydride and dry  $NH_3$  (D'Arcet, *A. Ch.* [2] 58, 294), and also by heating succinamide or ammonium succinate (Fehling, *A.* 49, 198; Laurent a. Gerhardt, *Compt. Chim.* 1849, 108; Menschutkin, *A.* 162, 165, 187; 182, 93). Large efflorescent crystals (containing aq) or octahedra (from acetone) (Bunge, *A. Suppl.* 7, 118), v. sol. water and alcohol, m. sol. ether. Not attacked by pure  $HNO_3$  (S.G. 1-53) (Franchimont, *R. T. C.* 6, 228). Converted by hot baryta water into succinamic acid, and finally into succinic acid. Alcoholic  $NH_3$  at 100° forms succinamide. Yields pyrrole on distillation with zinc-dust.  $KOH$  (6 mols.) and  $KBrO$  (1 mol.), acting for two hours at 60°, form (β)-amido-propionic acid [196°] (Hoogewerf a. Van Dorp, *R. T. C.* 10, 4). Bromine forms bromo-succinimide [225°] and bromo-maleimide [152°] (Kisielinski, *Sitz. W.* [2] 74, 561; cf. Kusseroff, *A.* 252, 158). Chlorine at 160° forms chloro- and di-chloro-maleimide.  $POCl_3$  forms a compound melting

Vol. IV,

at 145°–148° (Bernthsen, *B.* 18, 1047). A solution of bleaching-powder added to a solution of succinimide containing excess of HOAc forms

$C_4H_4 \begin{smallmatrix} CO \\ CO \end{smallmatrix} > NCl$  [148°], which separates from benzene in large crystals, and is reconverted by acids and alkalis into succinimide (Bender, *B.* 19, 2273). Hydroxylamine at 65° forms  $NH(CO.C_6H_4.CO.NH.OH)_2$  [171°], crystallising in needles, v. e. sol. water, and yielding a picrate  $B'C_6H_3N_2O_7$  [266°] (Garny, *B.* 24, 3434). Methyl cyanate forms  $C_4H_4 \begin{smallmatrix} CO.NH \\ CO.NMe \end{smallmatrix} > CO$  [149°], while  $EtNCO$  forms corresponding  $C_4H_4N_2O_5$  [95°] (Menschutkin, *A.* 178, 204).

**Salts**. —  $KC_4H_4NO_4$  2aq. Ppd. by adding alcoholic potash and ether to an alcoholic solution of succinimide (Landsberg, *A.* 215, 200). —  $KA'$ : needles. V. sol. water and alcohol. —  $BaA'_2$  2aq. —  $BaA'_2$  2aq. —  $MgA'_2$  3aq. —  $HgA'_2$  —  $NH_2.HgA'$ . —  $CH_3HgA'$ . —  $CyHgA'$ . —  $Cu_2A'_2(OH)_2$  9aq. —  $Cu_2A'_2(OH)_2$  2aq. —  $AgA'$  4aq. Needles. Converted by iodine into  $IC_4H_4NO_4$ , crystallising in dimetric prisms; *ac* = 1: 873, melting, with evolution of  $I_2$  at 136°. Silver succinimide is converted by succinyl chloride in ethereal solution into 'trisuccinimide'  $(C_4H_4O_4)_3N_2$  [83°], crystallising from ether (Gerhardt a. Chiozza, *A.* 90, 108). —  $AgA'NH_2$ : crystalline.

**Methylimide**  $C_2H_5.C_2O_2.NMe$ . [66-5°]. (234°). Formed by distilling methyllamine succinate. Plates. Got also by the action of conc.  $H_2SO_4$  on the oxim of β-acetyl-propionic acid (Kischbieth; Bredt a. Boeddinghaus, *A.* 251, 316).

**Ethylimide**  $C_2H_5.C_2O_2.NEt$ . [26°]. (234°). Formed by distilling acid ethylamine succinate (M.), and by adding alcoholic  $EtI$  to sodium succinimide (Landsberg, *A.* 215, 212). Long lancet-shaped crystals, v. sol. water, alcohol, and ether. Yields ethyl-pyrrole on distillation over zinc-dust.

**Allylimide**  $C_3H_5.C_2O_2.NC_3H_5$ . (245°). S.G.  $\frac{2}{3}$  1-1543;  $\frac{1}{2}$  1-1432. Formed by heating succinic acid with allyl thiocarbimide. Liquid, v. sol. water and alcohol.

**Ethylene-imide**  $(C_2H_5.C_2O_2.N)_2O.H_2$ . [251°]. (395°). Formed by heating succinic acid with the hydrate of ethylene-diamine at 180° (Mason, *C. J.* 55, 10). Prisms, sol. hot water, v. sl. sol. hot alcohol, insol. ether.

**Propylene-imide**  $(C_3H_5.C_2O_2.N)_2C_3H_5$ . [100°]. Formed from the anhydride and propylene-diamine (Strache, *B.* 21, 2360). Crystals (from benzene).

**Phenylimide**  $C_6H_5.C_2O_2.NPh$ . **Succinanil.** [156°] (L. a. G.; Kauder, *J. pr.* [2] 31, 17). [150°] (Hübner, *A.* 209, 373; Bischoff a. Nastvogel, *B.* 22, 1807) (above 300°). Formed by heating succinic acid with aniline, and crystallising the product from water and alcohol successively (Laurent a. Gerhardt, *A. Ch.* [3] 34, 179). Formed also by the action of  $POCl_3$  on  $C_6H_5(CO.NHPh).CO_2H$  in chloroform (Anschütz, *B.* 21, 957). Needles, sl. sol. hot water.  $PCl_5$  in presence of boiling  $POCl_3$  forms the phenylimide of di-chloro-maleic acid  $C_2Cl_2.C_2O_2.NPh$ . Alcoholic  $NH_3$  forms  $C_6H_5(CONH_2).CONHPh$ . Boiling lime-water forms  $C_6H_5(CO_2H).CONHPh$ . Fuming  $HNO_3$  forms an o-nitro-derivative [156°]

M M

and the *p*-nitro-derivative [205°–208°]. The salt  $C_4H_3O_5NC_6H_4SO_3Na$  is got by heating succinic acid with sodium amido-benzene *p*-sulphonate (Pellizzari, *G.* 18, 817).

**Benzylimide**  $C_6H_5C_2O_2NCHPh$ . [99°]. Formed from benzyl chloride, succinimide, and alcoholic NaOH (Werner, *C. J.* 55, 629). Six-sided prisms, sol. alcohol.

***o*-Tolylimide**  $C_6H_4(C_2O_2N)CH_3Me$ . [75°]. (345° uncor.). Formed by heating *o*-toluidine with succinic acid (Michael, *B.* 10, 579; Bechi, *B.* 12, 25, 321). Needles, v. sol. water.

***p*-Tolylimide**. [150°]. (345°). Needles (from water), sl. sol. cold water. Yields on nitration  $C_6H_4(C_2O_2N)CH_3Me(NO_2)[1:4:2]$  [140°] (Hübner, *A.* 209, 378).

**Tri-methyl-phenyl-imide**  $C_6H_3(C_2O_2N)CH_3Me_3$ . **Succinmesidil**. [137°]. Formed by heating succinic acid with mesidine (Eisenberg, *B.* 15, 1018). Pearly plates, sol. alcohol and ether, sl. sol. water.

(*a*)-**Naphthylimide**  $C_{10}H_7(C_2O_2N)CH_3H$ . [153°]. Formed by heating succinic acid with (*a*)-naphthylamine (Hahnemann, *B.* 10, 1713; Hübner, *A.* 309, 381; Pellizzari, *A.* 243, 158). Needles, m. sol. alcohol. Yields a di-nitro-derivative [250°]. The sulphonic acid  $C_{10}H_7(C_2O_2N)CH_3H.SO_3H$ , prepared from (*a*)-naphthylamine *p*-sulphonic acid, yields  $KA'2aq$  (Pellizzari, *G.* 18, 321).

(*β*)-**Naphthylimide**. [180°]. Colourless needles, v. sol. alcohol. Converted by KOHAq into  $CO_2H.C_2H_4.CO.NHC_{10}H_7$ , [192°] (Pellizzari, *A.* 248, 159).

**Benzimidide**  $C_6H_5C_2O_2NCHPh.NH$ . [212°]. Formed from acetyl-succinic ether  $C_6H_5O_2$ , benzamidine hydrochloride, and NaOHAq (Pinner, *B.* 22, 2620). Needles, sl. sol. cold acetone and ether, sol. alcohol.

**References**.—AMIDO-, BROMO-, BROMO-AMIDO-, CHLORO-, NITRO-, and OXY-SUCCINIC ACID and DI-iodo-SUCCINAMIC ACID.

**Isosuccinic acid** v. METHYL-MALONIC ACID.

**SUCCINIC ALDEHYDE**. Reduction of succinic anhydride, which might be expected to yield the aldehyde, forms instead the isomeric *γ*-oxy-butyric lactone.

**Oxim**  $C_4H_5(CH_3NOH)$ . [173°]. Formed by heating pyrrole with hydroxylamine hydrochloride at 100° and, together with ethylamine, by the action of hydroxylamine on *p*-ethyl-pyrrole (Ciamician, *B.* 17, 533; 22, 1963; 23, 1788). Small white crystals (from alcohol). May be reduced to tetramethylene-diamine  $C_4H_8(CH_2NH_2)_2$  [28°].

**Phenyl hydrazide**  $C_6H_5(CH_2N_2HPH)$ . [125°]. Formed by heating a solution of the oxim (1 pt.) in water (50 pts.) with phenyl hydrazine (5 pts.) dissolved in dilute HOAc (Ciamician, *B.* 22, 1974; 23, 1784). Small silky plates, v. sol. alcohol. Converted by cold conc. HClAq into a base  $C_{10}H_{10}N_2$ , [185°], which crystallises from EtOAc in needles, v. sl. sol. alcohol, and gives a deep-blue colour with  $K_2Cr_2O_7$  and  $H_2SO_4$ .

**Succinic semi-aldehyde**. **Nitrile**  $CN.CH_2.CH_2.CHO$ . ***β*-Cyanopropionic aldehyde** (77°). S.G. 1.89. Formed by heating  $C_4H_5CH_2.CHO$  (92 g.) with alcohol (180 g.) and AgCy (67 g.) for ten hours (Chautard, *A. Ch.* [6] 16, 182). Oil, not solid at –20°, miscible

with alcohol and ether. Reduces Fehling's solution. Does not combine with  $NaHSO_4$  or phenyl-hydrazine. Decomposed by hot alkalis and acids. Aniline at 850° forms the compound  $CH_2Cy.CH(NHPh)_2$ .

**Succinimidine**  $C_4H_5N$ , i.e.

$C_4H_5 \begin{smallmatrix} C(NH) \\ C(NH) \end{smallmatrix} NH$ . Formed, as hydrochloride, together with  $NH_4Cl$ , by the action of water on succinamidine (Pinner, *B.* 16, 862, 1657; 18, 2845).— $B''HCl$ : long plates, v. sol. water, sl. sol. alcohol. Converted by acetoacetic ether into crystalline  $C_6H_{11}N_2O_2$ .— $B''(HNO_3)_2$  4aq: leaflets (Grabowski, *A.* 265, 168).— $AgC_6H_5N_3$ : ppd. by adding ammoniacal  $AgNO_3$  to a solution of the hydrochloride.

**SUCCINIMIDO-ACETIC ETHER**  $C_6H_5NO_2$ , i.e.  $C_6H_5C_2O_2N.CH_2CO_2Et$ . [67°]. Formed by heating succinimide with alcohol, NaOEt, and  $CH_2Cl.CO_2Et$  (Haller a. Arth, *C. R.* 105, 280). Needles, v. sol. water, alcohol, and ether. Alcoholic NaOEt forms gelatinous  $C_6H_5NaNO_4$ .

**SUCCINIMIDO-ETHYL ETHER**  $C_6H_5N_2O_2$ , i.e.  $C_6H_5(C(NH).OEt)_2$ . The hydrochloride  $B''2HCl$  is prepared by passing gaseous HCl into an ethereal solution of ethylene cyanide (Pinner, *B.* 16, 359). It is v. sl. sol. alcohol and ether, and decomposed by water into succinic ether and  $NH_4Cl$ . With ammonia it gives  $C_2H_5(C(NH).NH_2)_2$ .

**SUCCINIMIDOXIM**  $C_4H_5 \begin{smallmatrix} C(NOH) \\ CO \end{smallmatrix} NH$ . [197°]. Formed by heating ethylene cyanide with alcoholic hydroxylamine at 65° (Garny, *B.* 24, 3427). White crystals, sol. water.— $B''HCl$ . [98°]. Needles.— $B'C_6H_5N_2O_2$ . [212°].

**Benzoyl derivative**

$C_6H_5 \begin{smallmatrix} C(NOBz) \\ CO \end{smallmatrix} NH$ . [184°]. Formed from the oxim, NaOH, and BzCl. White powder, sol. alcohol, sl. sol. ether.

**SUCCINOPHENONE** v. DI-PHENYL ETHYLENE DIKETONE.

**SUCCINOXYL-AMIDO-BENZOIC ACID** v. CARBOXY-PHENYL-SUCCINAMIC ACID.

**SUCCINYL-AMIDO-BENZOIC ACID** v. AMIDO-BENZOIC ACID.

**SUCCINYL-SUCCINIC ACID** v. DI-OXY-TEREPHTHALIC ACID DIHYDRIDE, vol. iii. p. 777.

**SUCCISTERENE**  $C_{15}H_{16}$ . [160°]. (above 300°). Occurs in the product of distillation of amber (Pelletier a. Walter, *A. Ch.* [3] 9, 96). Flat needles, nearly insol. cold alcohol, v. sl. sol. ether.

**SUGAR**, a term applied to the members of a group of carbohydrates in consequence of the property they possess of being sweet to the taste and of their relationship to the substance to which the term was originally given. The known natural members of this group are not very numerous. They are all easily soluble in water, crystallisable, and diffusible. When solutions of them are heated with alkaline solutions of the more easily reducible metals, reduction takes place with precipitation of the lower oxides in some cases, and of the metals in others; some sugars, before exhibiting this property, require to be digested with dilute mineral acids. Enzymes also convert some of the non-reducing members into reducing ones. With phenyl

hydrazine they yield *phenylhydrazides* and *phenylosazones*. Oxidising agents easily convert them into acids, and reducing agents into alcohols. Some of them undergo fermentation when submitted to the action of beer yeast, *i.e.* they are decomposed into alcohol,  $\text{CO}_2$ , &c. They yield solutions which are optically active, those of some rotating the plane of polarisation to the right, of others to the left. They give colour reactions with aromatic acids and phenols.

The group may be divided into two classes: (1) those which, when digested with dilute acids, do not yield any other sugar or sugars—the sugars of this class are distinguished by the termination *-ose*; (2) those which, when digested with dilute acids, do yield some other sugar or sugars—these sugars are distinguished by the termination *-on*. They are designated according to the number of carbon atoms they contain: thus, pentose containing  $\text{C}_5$ , hexose containing  $\text{C}_6$ , &c., and di-penton containing  $\text{C}_{10}$ , di-hexon containing  $\text{C}_{12}$ , &c.

The members of the *-ose* class are:

Triose  $\text{C}_3\text{H}_6\text{O}_3$ , glycero-  
 Tetroses  $\text{C}_4\text{H}_8\text{O}_4$ , erythro-  
 $\text{C}_4\text{H}_7(\text{C}_2\text{H}_5)\text{O}_4$ , phenyltetrose  
 Pentoses  $\text{C}_5\text{H}_{10}\text{O}_5$ , arabinose  
 " ribose  
 " xylose  
 $\text{C}_5\text{H}_7(\text{CH}_3)\text{O}_5$ , rhamnose (methyl  
 pentose)  
 " fucose (ditto)  
 Hexoses  $\text{C}_6\text{H}_{12}\text{O}_6$ , *d*-, *l*- and *i*-<sup>1</sup> glucoso (*d*-  
 glucose = dextrose)  
 " *d*-, *l*- and *i*-mannose  
 " *d*-, *l*- and *i*-gulose  
 " *d*-, *l*- and *i*-fructose (*d*-  
 fructose = levulose)  
 " *d*-, *l*- and *i*-galactose  
 " sorbose (sorbino-)  
 " formose  
 " lokaose  
 "  $\beta$ -acrose  
 $\text{C}_6\text{H}_{11}(\text{CH}_3)\text{O}_6$ , rhamnohexose  
 (methyl hexose).  
 Heptoses  $\text{C}_7\text{H}_{14}\text{O}_7$ , mannoheptose  
 "  $\alpha$ - and  $\beta$ -glucoheptose  
 " galaheptose  
 " fructoheptose  
 " digitalose  
 $\text{C}_7\text{H}_{13}(\text{CH}_3)\text{O}_7$ , rhamnoheptose  
 (methyl heptose).

Octoses  $\text{C}_8\text{H}_{16}\text{O}_8$ , mannooctose  
 "  $\alpha$ - and  $\beta$ -glucooctose  
 " glucononose

Nonoses  $\text{C}_9\text{H}_{18}\text{O}_9$ , mannnononose

The members of the *-on* group are:

Di-penton  $\text{C}_{10}\text{H}_{20}\text{O}_{10}$ , arabinon  
 Di-hexon  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ , cane-sugar (saccharon)  
 " milk-sugar, lactose  
 (lacton)  
 " maltose (di-glucon,  
 amylo-)  
 " iso-maltose  
 " melibiose  
 " trehalose  
 " cyclamose  
 " para-saccharose  
 " tewfikose (tewfikon)

Tri-hexon  $\text{C}_{18}\text{H}_{32}\text{O}_{16}$ , raffinose

melezitose

Hex-hexon  $\text{C}_{24}\text{H}_{42}\text{O}_{21}$ , gentianose

stachyose

**Occurrence.**—Some of these sugars have been obtained by synthesis, others are products of the action of dilute acids or ferments on more complicated bodies, and others occur naturally. The most important source of the latter is the vegetable kingdom. Little, if anything, is known concerning the formation of the sugars in nature; it is very probable that they are intermediate products of assimilation between  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , and starch, inulin, cellulose, and such bodies. For an account of the various theories, see textbooks of vegetable and animal physiology. The sugars found in animals are most probably of vegetable origin.

**Determination.**—Owing to the fact that the sugars possess many properties in common, the presence of a particular sugar can only be definitely proved by its isolation in the pure state, and a determination of its optical activity, reducing power, and other definite distinguishing properties (*v. end of art.*).

**Molecular Weight.**—Until quite recently none of the accepted methods for determining molecular weights were applicable to the sugars. At the present time there are several, chief among which are the physical methods of Raoult (*A. Ch.* [5] 28, 133; [6] 2, 66-124; [6] 4, 401; [6] 8, 289 a. 317), and De Vries, which are of general application, and the various chemical ones which are of special application. By Raoult's method Brown and Morris (*C. J.* 1888, 610; 1889, 462), Tollens and Mayer (*B.* 21, 1566), and Tollens, Mayer, and Wheeler (*B.* 21, 3508), Ekstrand and Mauzelus (*Vetensk. Akad. för Handl.* 1889, 157), and O'Sullivan (*C. J.* 1890, 62) have determined the molecular weight of xylose and arabinose to be 150, corresponding to a formula  $\text{C}_5\text{H}_{10}\text{O}_5$ ; of dextrose, levulose, galactose to be 180, corresponding to a formula  $\text{C}_6\text{H}_{12}\text{O}_6$ ; of arabinon to be 282, corresponding to a formula  $\text{C}_{10}\text{H}_{20}\text{O}_{10}$ ; of cane sugar, maltose, lactose to be 342, corresponding to a formula  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ; and of raffinose to be 504, corresponding to a formula  $\text{C}_{18}\text{H}_{32}\text{O}_{16}$ . These numbers have been confirmed in the case of the simpler sugars by various chemical methods (see succeeding paragraphs). In the case of arabinose it was first shown to be  $\text{C}_5\text{H}_{10}\text{O}_5$  by Kiliani (*B.* 20, 339) by the analysis of some of its compounds, its formula previously having been considered to be  $\text{C}_6\text{H}_{12}\text{O}_6$ .

**Synthesis.**—The first step towards the synthesis of the sugars was made by Butlerow (*A.* 120, 295; *C. R.* 53, 145). He obtained a sweet syrup, having the common characteristics of the sugars, by adding lime-water to a hot solution of di-oxymethylene; the product he called *methyl-enitan*, and considered its formula to be  $\text{C}_6\text{H}_{12}\text{O}_6$ . The next step was made by Loew (*J. pr.* 33, 321), who, having discovered a method for the preparation of formaldehyde ( $\text{CH}_2\text{O}$ ) in quantity, investigated its condensation by lime-water. He obtained a sweet syrup, which he called *formose*, and considered it to have a formula  $\text{C}_6\text{H}_{12}\text{O}_6$ . Neither methylenitan nor formose fermented with yeast (see also Tollens, *B.* 19, 2133). Fischer (*B.* 21, 989) finds these products to be a mixture of various saccharine bodies,

<sup>1</sup> *d*, *l*, and *i*. Fischer's notation, see p. 532.

the chief which is a sugar, formose,  $C_6H_{12}O_6$ , yielding an osazone  $C_8H_{12}N_4O_4$ , m.p.  $144^\circ$ . Another sugar is present in smaller quantities in the condensation products of formaldehyde. It yields an osazone greatly resembling glucosazone, which has been identified with  $\alpha$ -acrosazone. Later, Loew (*B.* 22, 475), by the condensation of formaldehyde with lead oxide and magnesia, obtained a sugar which is fermentable. Loew called this *methose*, but Fischer has shown it to be identical with  $\alpha$ -acrose.

Acrose was obtained by Fischer (*B.* 20, 1093 and 2566) by acting on acrolein bromide with bases  $2C_2H_5OBr_2 + 2Ba(OH)_2 = C_6H_{12}O_6 + 2BaBr_2$ . Two isomeric sugars,  $\alpha$ -acrose and  $\beta$ -acrose, are thus produced.

Glycerose yields these two sugars by the action of alkalis. (Glycerose is a sugar  $C_6H_{12}O_6$ , obtained by the action of bromine and soda on glycerol and other methods by Van Deen, *J.* 1863, 501; Grimaux, *C. R.* 104, 1276; and Fischer a. Tafel, *B.* 20, 1088 and 3385; 22, 106. It is probably a mixture of the aldehyde and ketone of glycerol.) The formation of  $\alpha$ -acrose from glycerose may be represented  $CH_2(OH).CH(OH).COH + CH_2.OH.CO.CH_2.OH = CH_2.OH.CH(OH).CH(OH).CH(OH).CO.CH_2.OH$ . The sugars can only be separated from the products thus obtained as osazones;  $\alpha$ -acrosazone is identical with glucosazone in every way except in its action on polarised light.

$\alpha$ -acrosazone

||

acted on by fuming hydrochloric acid, is converted into  $\alpha$ -acrosone  $CH_2.OH.(CH.OH).CO.CO.H$ , which, when reduced by zinc and acetic acid, yields a sugar  $CH_2.OH.(CH.OH).CO.CH_2.OH$ , in the form of a sweet syrup; it ferments with yeast, yields levulinic acid when heated with hydrochloric acid, and is reduced by sodium-amalgam to a hexahydric alcohol  $\alpha$ -acritol, which resembles mannitol in every way except that it is optically inactive. By these various reactions so much is lost that from 1 kilo. glycerol only 0.2 g. acritol is obtained. Further, all the bodies obtained in the processes were optically inactive. More knowledge was necessary before the natural sugars could be synthesised. At this stage a new light was thrown on the subject by an observation of Fischer (*B.* 23, 370) that arabinose carboxylic acid and mannonic acid were identical in every way except that their optical activities, although equal, were opposite in sign, and that they combined to form an optically inactive acid. These three acids were reduced by sodium-amalgam to three sugars resembling one another in all respects except that one of them had a right-handed optical activity, the other an equal but left-handed one, while the third was optically inactive. They are named *l-mannose*, *i-mannose*, and *d-mannose*;<sup>1</sup> by further reduction they yielded the corresponding hexahydric alcohols *l-mannitol*, *i-mannitol*, and *d-mannitol*.

The sugar obtained from  $\alpha$ -acrosazone as

<sup>1</sup> *l*, *i*, and *d* are very unsatisfactory, and somewhat misleading; but as Fischer has introduced them we must let them stand. A little study will make their meaning clear.

above described is identical with levulose except that it is inactive. If, then, we can decompose this levulose into *d*-levulose and *l*-levulose, the synthesis of the natural sugar will be accomplished. This Fischer has done (*B.* 23, 370). If *i*-levulose be submitted to the action of yeast, the *l*-*l*-constituent ferments and the residue is dextrorotatory. This is *l*-levulose; it is not the natural sugar: that belongs to the *d*-group, and was destroyed by the ferment.

To obtain the natural sugar from the inactive synthetic one, Fischer proceeded as follows:—*i*-mannitol, i.e.  $\alpha$ -acritol, is oxidised by nitric acid to *i*-mannose, and this further by bromine-water to *i*-mannonic acid. By fractional crystallisation of the strychnine or morphine salts it can be mesotomised, the result being *d*- and *l*-mannonic salts, which, on being freed from the base, yield by reduction the corresponding mannoses and mannitols. These, by means of the osazones, can be converted into the corresponding levuloses (see *Dextrosazone*).

Dextrose and mannose both yield the same osazone; the difference in their constitution must therefore be caused by the position of the group marked with a \* in the formula

Fischer (*B.* 23, 799 a. 2611) found that by heating gluconic acid with quinoline, part was converted into mannonic acid and part unaltered; and also that mannonic acid, treated in the same way, yielded some gluconic acid. Dextrose may then be obtained by reducing the gluconic acid thus obtained. The corresponding reaction with *l*-mannonic acid does not take place easily, if at all, but *l*-gluconic acid is produced simultaneously with arabinose carboxylic acid (*l*-mannonic acid) by Kiliani's mode of preparation (see *Arabinose*). From *l*-gluconic acid, by reduction, *l*-glucose, the optical isomer of dextrose, is obtained. The table on next page gives a concise view of the synthesis of dextrose, levulose, and mannose.

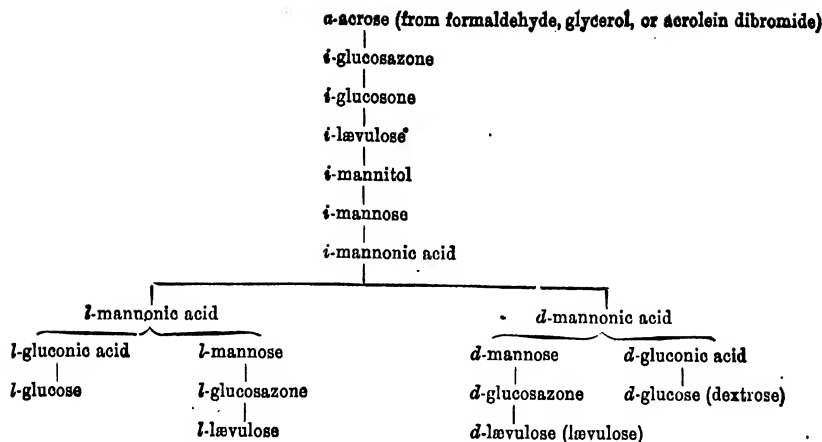

Another sugar, *gulose*, stereoisomeric with glucose, has been obtained by Fischer (*B.* 23, 93; 24, 521) by the reduction of saccharic acid, the *d*-, *l*- and *i*-modifications being obtained by the reduction of *d*-, *l*- and *i*-saccharic acids. As these are the products of the oxidation of *d*-, *l*- and *i*-glucose, the synthesis of gulose is complete.

Galactose has not been synthesised up to the present (June 1893), but by the reduction of mucic acid Fischer and Hertz (*B.* 25, 1247) have obtained *i*-galactonic acid and *i*-galactose; *i*-galactonic acid, by the fractional crystallisation of its strychnine salt, may be mesotomised into *d*- and *l*-galactonic acids from which *d*- and *l*-galactose are obtained; *d*-galactose is identical with ordinary galactose.

Arabinose has not been directly synthesised, but its relationship to the synthetical sugars is shown by the fact that the two acids obtained from arabinose by the nitrile reaction are *l*-mannonic acid and *l*-gluconic acid (Fischer, *B.* 23, 2611; 24, 539).

Of xylose the same must be said; but by the nitrile reaction it yields *l*-gulonic acid (Fischer a. Stahel, *B.* 24, 528).

Arabinic acid, when heated with quinoline, is partly changed into its stereoisomeric ribonic

acid, just as gluconic acid yields gulonic acid; ribonic acid, by reduction, yields the stereoisomeride of arabinose, which it is proposed to call *ribose*.

The synthetical passage from an *-ose* sugar to an *-on* one is said to be accomplished for lactose (lacton) and cane sugar (saccharon) as well as for maltose (amylon).

**Lacton.** A mixture of dextrose and galactose, is acted on by acetic anhydride, and the resulting products, carefully saponified with alkali, yield lacton (Demole, *C. R.* 89, 491). This has been contradicted by Berthelot (*Bl.* [2] 34, 82) and by Herzfeld (*A.* 220, 219).

**Sucron.** A body having a dextrorotatory power, and by inversion becoming levorotatory, was obtained by acting on aceto-chlorhydrate (a derivative of dextrose) with an alcoholic solution of lævulose in the presence of barium carbonate. Another body which was levorotatory, and became less levorotatory on inversion, was obtained by acting on aceto-chlorhydrate by sodium lævulosate (Colley & Vakovitch, *Bl.* [2] 34, 826).

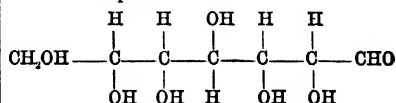

**Isomallose** has been prepared by Fischer (*B.* 23, 8687) by the action of HCl on dextrose. Dilute acids again hydrolyse it to dextrose, the same product as is yielded by maltose.

**Phenyl-tetrose** has been prepared synthetically from cinnamaldehyde cyanhydrin; this, by the action of bromine, yielding phenyl-dibromoxy-butyronitrile  $\text{CH.Ph.Br.CH.Br.CH.OH.CN}$ , which, when heated with hydrochloric acid, yields phenyl-bromo-di-oxy-butyrolactone, from which the corresponding acid  $\text{OH.CH.Ph.CHBr.CH.OH.COOH}$  is easily obtained, and which on reduction yields the sugar  $\text{OH.CH.Ph.CH(OH).CH(OH).COH}$ .

It will not be out of place here to indicate what has been done in the way of converting a sugar into one containing a carbon atom more. To do this, Fischer (*B.* 22, 2204; 23, 370, 799, 980, 2226, and 8102; *Ann.* 270, 64) made use of the well-known reaction for proceeding from one alcohol to its next higher homologue by means of the nitrile. Now, in this reaction, where an asymmetric carbon atom is added to the molecule,

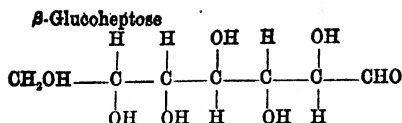

Van't Hoff has predicted that two isomeric bodies will be formed which will differ by the arrangement of the groups round the new carbon atoms. Fischer (*Ann.* 270, 64) has shown that this is so in the case of the glucose homologues, the two acids obtained from glucose being  $\alpha$ - and  $\beta$ -glucoheptonic acids;  $\alpha$ -glucoheptonic acid is always the principal product of the reaction, and is identical with the dextrose carboxylic acid described by Kiliani (see *Dextrose*). When the reaction takes place at 20°–25° hardly a trace of the  $\beta$ -acid is formed; but at 40° about 13 p.c. of the latter is obtained. By oxidation these acids yield two penta-oxy-pimelic acids, the  $\alpha$ -acid being optically inactive, and by reduction the two sugars  $\alpha$ - and  $\beta$ -glucoheptose are obtained.

#### $\alpha$ -Glucoheptose

separates from its aqueous solution in rhombic prisms, m.p. 180°–190°; they have a faintly sweet taste, dissolve in 10.5 pts. of water at 14°, and are easily soluble in hot water and sparingly in hot alcohol. Its solution is optically active. Freshly-prepared solutions show a slight bi-rotation; for a 10 p.c. solution,  $[\alpha]_{D^{20}} = -19.7^\circ$ . It does not ferment with yeast, but reduces Fehling slightly less than dextrose. It is oxidised by bromine to  $\alpha$ -glucoheptonic acid. It yields a hydrazone  $\text{C}_7\text{H}_{11}\text{O}_4\text{N}_2\text{H}_2$ , very soluble in water, m.p. 170°, and also an osazone  $\text{C}_7\text{H}_{12}\text{O}_4(\text{N}_2\text{HC}_6\text{H}_5)_2$ , forming yellow needles, m.p. 195°, almost insoluble in water and difficultly in hot alcohol. Treated with acetic anhydride and zinc chloride it yields a hexacetate, m.p. 166°, and with sodium acetate and acetic anhydride it yields *dec-acetyl-diglucoheptose*  $\text{C}_{11}\text{H}_{18}(\text{C}_2\text{H}_3\text{O})_2\text{O}_m$ , m.p. 131°–132°.

By reduction with sodium-amalgam,  $\alpha$ -glucoheptose yields  $\alpha$ -glucoheptitol, which crystallises in delicate prisms, m.p. 127°–128°, is optically inactive, easily soluble in water and sparingly in alcohol. It yields a heptacetate derivative  $\text{C}_7\text{H}_8(\text{C}_2\text{H}_3\text{O})_7\text{O}_m$ .

is obtained by the reduction of  $\beta$ -glucoheptonic acid, it has not yet been obtained in a crystalline state, it forms a phenyl-hydrazone  $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{H}_2\text{C}_6\text{H}_5$ , crystallising from alcohol in slender needles, m.p.  $192^\circ$ ; the osazone is identical with  $\alpha$ -glucoheptosazone.

Just as dextrose yields two isomeric glucoheptonic acids, so  $\alpha$ -glucoheptose yields two isomeric glucoheptonic acids. The  $\alpha$ -acid is the chief product, and the amount of  $\beta$ -acid formed varies with the temperature.  $\alpha$ -Glucoheptonic acid yields a lactone  $\text{C}_6\text{H}_{10}\text{O}_6$ , sparingly soluble in alcohol and readily in water, m.p.  $145^\circ$ – $147^\circ$   $[\alpha]_{\text{D}20} = -45.9$ ; by reduction with sodium-amalgam it yields  $\alpha$ -glucoheptose  $\text{C}_6\text{H}_{12}\text{O}_6 \cdot 2\text{H}_2\text{O}$ , which crystallises in colourless needles, m.p.  $93^\circ$ . Its aqueous solutions are optically active and show bi-rotation,  $[\alpha]_{\text{D}20} = -50.5^\circ$  for the anhydrous sugar. It yields a phenyl hydrazone  $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{H}_2\text{C}_6\text{H}_5$ , m.p.  $190^\circ$ , and an osazone  $\text{C}_6\text{H}_8\text{O}_4(\text{N}_2\text{HC}_6\text{H}_5)_2$ , m.p.  $210^\circ$ – $212^\circ$ , almost insoluble in water. By reduction with sodium-amalgam it yields  $\alpha$ -glucoheptitol  $\text{C}_6\text{H}_{12}\text{O}_6$ , which is easily soluble in water; it forms slender white needles, m.p.  $141^\circ$ . From  $\alpha$ -glucoheptose two glucononic acids may be prepared. Only one has been examined; this when reduced yields glucononose  $\text{C}_6\text{H}_{12}\text{O}_6$ , its phenyl-hydrazone  $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{H}_2\text{C}_6\text{H}_5$ , is sparingly soluble in cold water and alcohol, m.p.  $195^\circ$ – $200^\circ$ , its phenyl osazone  $\text{C}_6\text{H}_8\text{O}_4(\text{N}_2\text{HC}_6\text{H}_5)_2$ , is sparingly soluble in hot water and alcohol, m.p.  $220^\circ$ – $223^\circ$ . Unlike mannononose, glucononose does not ferment with yeast. By reduction glucononitol is obtained.

**Mannoheptose**  $\text{C}_6\text{H}_{12}\text{O}_6$ , is obtained by the reduction of mannoheptonic acid. It crystallises from alcohol in fine needles, it has a sweet taste, m.p.  $134^\circ$ – $135^\circ$ . It is easily soluble in water, and does not ferment with yeast; its solution is dextrorotatory and exhibits bi-rotation, the constant value is  $[\alpha]_{\text{D}} = +68.6^\circ$ . It yields a difficultly soluble hydrazone  $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{H}_2\text{C}_6\text{H}_5$ , m.p.  $197^\circ$ – $200^\circ$ , and an osazone  $\text{C}_6\text{H}_8\text{O}_4(\text{N}_2\text{HC}_6\text{H}_5)_2$ , m.p.  $200^\circ$ . By reduction with sodium-amalgam it yields a heptahydric alcohol which is identical with the naturally produced body, perseitol (Maquenne, *A. Ch.* [5] 19, 1; *C. R.* 107, 583). It combines with hydrocyanic acid, and the compound decomposed by hydrochloric acid yields mannoctonic acid.

**Mannoctose**  $\text{C}_6\text{H}_{12}\text{O}_6$ , is obtained by the reduction of mannoctonic acid. It is easily soluble in water, has a sweet taste, and does not ferment with yeast. Its aqueous solutions are laevorotatory,  $[\alpha]_{\text{D}} = -8.3^\circ$ . It yields a hydrazone  $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{H}_2\text{C}_6\text{H}_5$ , difficultly soluble in water, m.p.  $212^\circ$ ; and an osazone  $\text{C}_6\text{H}_8\text{O}_4(\text{N}_2\text{HC}_6\text{H}_5)_2$ , m.p.  $223^\circ$ . By reduction it yields the octohydric alcohol mannoctitol. It combines with hydrocyanic acid, and the compound decomposed by hydrochloric acid yields mannonononic acid.

**Mannononose**  $\text{C}_6\text{H}_{12}\text{O}_6$ , is obtained by the reduction of mannonononic acid. It is easily soluble in water and crystallises from alcohol, m.p. about  $180^\circ$ , its solution is dextrorotatory,  $[\alpha]_{\text{D}}$

$= +50^\circ$  approx. It ferments readily and completely with yeast, and resembles dextrose in many ways. It yields a difficultly soluble hydrazone  $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{H}_2\text{C}_6\text{H}_5$ , m.p.  $223^\circ$ , and an osazone, m.p.  $217^\circ$ .

**Galactoheptose**  $\text{C}_6\text{H}_{12}\text{O}_6$ , is obtained by the reduction of galacto-heptonic acid. Its hydrazone (m.p.  $199^\circ$ ) is sparingly soluble; so is its osazone (m.p.  $220^\circ$ ).

**Fructoheptose** is obtained from l  vulose by the same set of reactions.

**Rhamnohexose**  $\text{CH}_2(\text{CH.OH})_4\text{COH}$  is obtained by the reduction of rhamnohexolactone (Fischer a. Piloty, *B.* 23, 3102); it does not ferment with yeast, but exhibits all the characters of a sugar; the osazone is obtained in stellate groups of needles, m.p.  $200^\circ$ . On reduction the sugar yields *rhamnohexitol*  $\text{CH}_2(\text{CH.OH})_4\text{CH}_2\text{OH}$ ; by the action of hydrocyanic acid on rhamnohexose, the lactone of rhamnoheptonic acid is obtained, which on reduction yields *rhamnoheptose*. The osazone forms yellow needles, m.p.  $200^\circ$ ; by the action of hydrocyanic acid, *rhamnooctonic* acid is obtained. These compounds have the following optical activities:—

Rhamnose,  $[\alpha]_{\text{D}} = +8^\circ$ .

Rhamnohexose,  $[\alpha]_{\text{D}} = -61.1^\circ$ .

Rhamnoheptose,  $[\alpha]_{\text{D}} = +8.4^\circ$ .

Rhamnitol,  $[\alpha]_{\text{D}} = +10.7^\circ$ .

Rhamnohexitol,  $[\alpha]_{\text{D}} = +11.6^\circ$ .

Rhamnohexonolactone,  $[\alpha]_{\text{D}} = +83.8^\circ$ .

Rhamnoheptolactone,  $[\alpha]_{\text{D}} = +55.6^\circ$ .

Rhamnoctonolactone,  $[\alpha]_{\text{D}} = -51.2^\circ$ .

The reverse of the method of proceeding from one sugar to its next higher homologue—i.e. the production of a sugar containing one less carbon atom than the original one—has been effected by Wohl (*B.* 26, 730). When dextrose oxim (*vide* below) is treated with acetyl chloride it yields an acetyl compound from which hydrocyanic acid can be eliminated, and on hydrolysis of the resulting compound a pentose is obtained, which is *d-arabinose*; *l-arabinose* (ordinary arabinose) treated in the same way as dextrose yields a tetrose.

As is well known, mucic and saccharic acids are products of the oxidation of the sugars with nitric acid. The action of reducing agents on these bodies indicates their relationship to the sugars and helps to a clearer idea of the synthetic process.

**Reduction of mucic acid.** Sulphuric acid and zinc-dust reduce mucic acid to *i*-galactonic acid (Fischer a. Hertz, *B.* 25, 1247). The lactone crystallises in delicate prisms, m.p.  $122^\circ$ – $125^\circ$ . It is optically inactive. By further reduction with sodium-amalgam *i*-galactose is obtained. This can be prepared as a crystalline mass, m.p.  $140^\circ$ – $142^\circ$ ; it yields a hydrazone, m.p.  $158^\circ$ – $160^\circ$  and an osazone, m.p.  $195^\circ$ , which is identical with that obtained from the oxidation product of dulcitol (Fischer a. Tafel, *B.* 20, 3384).

*i*-Galactonic acid may be separated into the *d*- and *l*-acids by fractional crystallisation of the strychnine salts. The two acids yield respectively *d*- and *l*-galactose; *d*-galactose is identical with ordinary galactose. *l*-Galactose may also be obtained by the fermentation of *i*-galactose syrup. The sugar crystallises from alcohol, m.p.  $162^\circ$ – $163^\circ$ , its specific rotatory power is  $[\alpha]_{\text{D}} = -78.6^\circ$ , the phenyl-hydrazone

melts at 158°-160° and the osazone at 192°-195°. From this, as well as from other matters connected with the synthetical portion of the work, it will be seen that *d*-, *i*-, and *l*- were intended to mean dextro-, inactive, and lævo-, as indicating the optical activity of the substances to which they are prefixed; but it is obvious the *d*-body is not always dextro-, nor the *l*-body lævo-. Hence the unsatisfactoriness already indicated.

**Reduction of saccharic acid.** Fischer (B. 23, 990; 24, 621) found that the lactone of saccharic acid was easily reduced by sodium-amalgam with formation of glycuronic acid. Thierfelder (H. 15, 71) has shown that this latter is further reduced to an acid  $C_6H_{10}O_7$  which reaction Fischer has confirmed, and calls the acid *gulonic acid* and the corresponding sugar *gulose*. The relationship of these bodies to the others of the sugar group is shown here:

Dextrose	$\cdot \text{OH} \cdot \text{CH}_2 \cdot (\text{CH} \cdot \text{OH})_4 \cdot \text{COH} \cdot$
Gluconic acid	$\cdot \text{OH} \cdot \text{CH}_2 \cdot (\text{CH} \cdot \text{OH})_4 \cdot \text{COOH} \cdot$
Saccharic acid	$\cdot \text{COOH} \cdot (\text{CH} \cdot \text{OH})_4 \cdot \text{COOH} \cdot$
Glycuronic acid	$\cdot \text{COOH} \cdot (\text{CH} \cdot \text{OH})_4 \cdot \text{COH} \cdot$
Gulonic acid	$\cdot \text{COOH} \cdot (\text{CH} \cdot \text{OH})_3 \cdot \text{CH}_2 \cdot \text{OH} \cdot$
Gulose	$\cdot \text{COH} \cdot (\text{CH} \cdot \text{OH})_3 \cdot \text{CH}_2 \cdot \text{OH} \cdot$

*Glycuronic acid* obtained by the reduction of *d*-saccharic acid has  $[\alpha]_D = +19.1^\circ$ , m.p.  $175^\circ$ – $178^\circ$ ; *d*-gulonic acid obtained by the reduction of glycuronic acid yields a lactone, m.p.  $180^\circ$ – $181^\circ$ ,  $[\alpha]_D = +55^\circ$ ; its phenyl-hydrazide is easily soluble in hot water and hot alcohol, m.p.  $147^\circ$ – $149^\circ$ ; *d*-gulose obtained by the reduction of *d*-gulonic lactone is a colourless syrup, easily soluble in water and sparingly in absolute alcohol, it is oxidised by nitric acid to saccharic acid, it does not ferment with yeast.

CONSTITUTION. Dextrose and galactose are represented by the formula

represented by the formula  
 $\text{CH}_2(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{COH}$   
 and lævulose by

and therefore by  
 $\text{CH}_2(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CH}(\text{OH}).\text{CO}.\text{CH}_2.\text{OH}$   
 and for the following reasons.

By oxidation dextrose and galactose yield acids containing the same number of carbon atoms as themselves, whilst *l*avulose yields acids containing less carbon atoms than itself; dextrose and galactose yielding gluconic and galactonic acids  $\text{CH}_2(\text{OH})[\text{CH}(\text{OH})]\cdots\text{COOH}$  and by further oxidation saccharic and mucic acids  $\text{COOH}[\text{CH}(\text{OH})]\cdots\text{COOH}$  respectively; whilst *l*avulose gives rise to trioxibutyric  $\text{CH}_2(\text{OH})[\text{CH}(\text{OH})]\cdots\text{COOH}$ , formic  $\text{H}\cdot\text{COOH}$ , and glycolic  $\text{CH}_2\text{OH}\cdot\text{COOH}$  acids.

By reduction dextrose and galactose yield respectively mannitol and dulcitol; levulose also yields mannitol. These yield hexacetyl derivatives, and are reduced by hydriodic acid to secondary hexyl iodide  $\text{CH}_3(\text{CH}_2)_4\text{CH}_2\text{CH}_3$  (Wanklyn & A. Erlenmeyer, *J.* 1861. 731; 1862. 480); they are evidently hexahydric alcohols of normal hexane.

All three sugars combine with hydrocyanic acid to form nitriles which when boiled with hydrochloric acid yield different acids  $C_3H_5O_3$ , which are reduced by hydriodic acid to heptioic acids; dextrose and galactose yielding normal heptioic acid  $CH_2(CH_2)_4COOH$  and *l*-xylulose yielding methyl-butyl-acetic acid  $CH_3CH_2COOH$  (Kilian, B. 18, 8066; 19, 221, 707 a. 1198). Galactose, dextrose, and *l*-xylulose

form oxims or iso-nitroso-compounds by combination with hydroxylamine (Rischbieth, *B.* 20, 2673; Jacobi, *B.* 24, 696; Wohl, *B.* 24, 993). With phenylhydrazine, dextrose and galactose yield hydrazides

$\text{CH}_3(\text{OH})\{\text{CH}(\text{OH})\}_n\text{CH}_2\text{N}_2\text{H}_4\text{C}_6\text{H}_5$ ;  
 hevlulose does not; but there are three yield ozonones  
 $\text{CH}_2(\text{OH})\{\text{CH}(\text{OH})\}_n\text{C}_6\text{H}_5$ ,  $\text{C}_6\text{H}_5\text{C}_6\text{H}_4$ ,  $\text{CH}_2\text{N}_2\text{H}_4\text{C}_6\text{H}_5$ .  
 All three yield pentacetyl derivatives (Erwig a.  
 Koenigs, B. 22, 2207). Previous to Fischer's  
 synthetic work, other formulæ had been sug-  
 gested (Tollens, *Kurzes Handbuch d. Kohlen-*  
*hydrate*; B. 16, 921; Sorokin, J. pr. [2] 37,  
 312), but there is no doubt now that the above  
 are correct.

From the synthetic work above described, it is evident that the aldehyde formula belongs also to mannose, gulose, arabinose, xylose, and ribose, and also their synthetic homologues. Rhamnose, as is evident from its reactions, has also an aldehyde constitution; it appears to be methyl-arabinose.

Sorbose appears to be isomeric with lævulose. By oxidation it yields tri-oxylglutaric acid,  $\text{COOH}\cdot\{\text{CH}(\text{OH})\}_2\cdot\text{COOH}$  and other acids, and by reduction it yields mannitol. It combines with hydrocyanic acid. By reduction with hydriodic acid and phosphorus it yields hexyl iodide (Kiliani & Scheibler, *B.* 21, 3276).

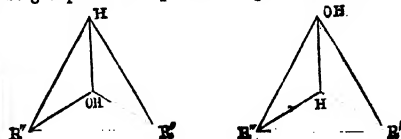

Little is known concerning the *-on* sugars. Maltose and lactose are probably anhydrides of equal molecules of dextrose and dextrose, and dextrose and galactose respectively; they yield acids (maltobionic and lactobionic) which on boiling with dilute mineral acids are decomposed into dextrose and gluconic acid and galactose and gluconic acid respectively. Both sugars thus appear to contain the dextrose-aldehyde group unaltered. Fischer (B. 21, 2633) has represented lactose as

Cane sugar appears to be differently constituted from either maltose or lactose.

It thus appears that the formula  $\text{CH}_2(\text{OH})\{\text{CH}(\text{OH})\}_n\text{COH}$  must be assigned to eight known sugars—i.e. *d*- and *l*-glucose; *d*- and *l*-gulose, *d*- and *l*-mannose, *d*- and *l*-galactose (the *i*-modifications being analogous to racemic acid, i.e. compounds of the *d*- and *l*-modifications).

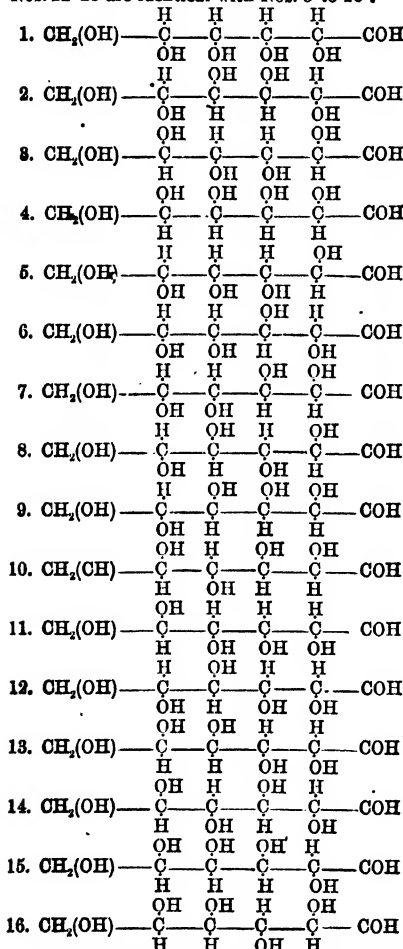

Now, as this formula contains four asymmetric carbon atoms, according to Van't Hoff's theory there will be possible  $2^4 = 16$  isomers, which in the case of the symmetrical derivatives, as the hexahydric alcohols and dibasic acids, will be reduced to 10, of which  $\frac{1}{2}2^4 = 8$  compounds are grouped in pairs (*d*- and *l*-) and  $\frac{1}{2}2^1 = 2$  inactive, mesotomic (Fischer, B. 24, 1836, a. 2683; Van't Hoff, *La Chimie dans l'Espace* and *Dix Années dans l'Histoire d'une Théorie*). Each of the groups R' —C.H.OH—R' may be grouped in two positions represented thus

(the carbon atom being considered to be at the centre of the tetrahedron). For the sake of brevity these two groupings will be written

The sixteen possible modifications of the glucose formula may then be expressed by the following symbols; in the case of the symmetrical derivatives (hexahydric alcohols and dibasic acids) Nos. 11-16 are identical with Nos. 5 to 10 :-

Since saccharic acid may be obtained either from glucose or its stereoisomeride gulose, then the *d*- and *l*-saccharic acids must be represented by formulae corresponding to two of those numbered 5 to 10. Now, 7 and 8 may be eliminated, as they are optically inactive from internal compensation. Nos. 6 and 10 may be excluded for the following reasons: Glucose and mannose yield the same osazone, and consequently differ only in the arrangement of the groups round the asymmetric carbon atom next to the COH group. Other facts which confirm

these formulae are (1) *l*-gluconic and *l*-mannonic acids are both produced by the nitrile reaction from arabinose; (2) fructose reduced by sodium-amalgam yields mannitol and sorbitol; (3) mannonic and gluconic acids can be converted, one into the other, by heating with quinoline; (4) all attempts to resolve gluconic and mannonic acids into two components have been unsuccessful.

If saccharic acid has the configuration 6 or 10, then manno-saccharic acid must have the configuration 7 or 8; but the latter are optically inactive, and therefore cannot be the configuration of manno-saccharic acid. Hence *d*- and *l*-saccharic acid must have a configuration corresponding to 5 and 9; for convenience we may assign 5 to the *d*- and 9 to the *l*-bodies.

Now the two sugars corresponding to *d*-saccharic acid—*i.e.* *d*-glucose and *d*-gulose—must consequently have the configuration 5 and 11; but in order to determine which to assign to one and which to the other, we must consider xylose and arabinose.

Arabinose by the nitrile reaction yields *l*-glucose and xylose yields *l*-gulose; now since *l*-glucose and *l*-gulose are

and (15)

then xylose and arabinose must be

According to theory, there will be  $2^3 = 8$  isomeric pentoses, but when the formula becomes symmetrical, the asymmetry of the centre carbon is destroyed, and there will be only three isomeric pentahydric alcohols and three isomeric tri-oxy-glutaric acids, of which two are optically active, *i.e.*:

and one is optically inactive, *i.e.*

The same applies to the pentahydric alcohols.

As arabitol and the tri-oxy-glutaric acid from arabinose are both levorotatory, whilst the corresponding compounds from xylose are optically inactive, the formula marked (a) is the formula for xylose, and (b) is the formula for arabinose, (9) and (15) being the formulae for *l*-gulose and *l*-glucose respectively.

*d*-gulose will consequently be

*d*-glucose*d*-mannose*l*-mannose

As *l*ævulose yields the same osazone as mannose and glucose,  
*d*-fructose

and *l*-fructose

The alcohols will be represented as follows:

*d*-mannitol*l*-mannitol*d*-sorbitol*l*-sorbitol

and the dibasic acids:

*d*-monosaccharic*l*-mannosaccharic*d*-saccharic*l*-saccharic

The other di-basic acids known are mucic acid, which is optically inactive; allomucic acid, formed by the action of pyridine on mucic acid, which is also optically inactive; another isomeride of mucic acid, which is optically active, obtained by treating galactonic acid with quinoline and oxidising the product; and iso-saccharic acid. We have as yet not sufficient data to write the constitution of these with certainty.

So far we have considered the sugars in general; we must now turn to a description of the individual members of the group.

*Class I. -Ose sugars.*

*Arabinose*  $\text{C}_5\text{H}_{10}\text{O}_5$ . It does not occur in nature.

**Formation.**—By the action of dilute acids on metapaetic acid, a constituent of beetroot, gum arabic, cherry-tree gum, gedda gum, gum tragacanth, and many other gums (Scheibler, *B.* 1, 58, 108; 6, 612; Claesson, *B.* 14, 1271; Martin, *Sachsse's Phytochem. Unter.* p. 69; Bauer, *J. pr.* [2] 84, 47; Kiliani, *B.* 19, 8030; v. Sandersleben, *Sachsse, l.c.*, p. 90; O'Sullivan, *C. J.* 1884. 41, 1891, 1029; Stone a. Tollens, *A.* 249, 257; Stone, *Am.* 12, 435); wheat and rye bran (*B.* 23, 8110). Owing to the fact that most of the above gums yield galactose besides arabinose, the two were for some time confused (H. Kiliani, *B.* 13, 2804; 15, 34; Claesson, *B.* 14, 1270; *B. C.* 205; Scheibler, *B.* 17, 1729; E. O. v. Lippmann, *B.* 17, 2238). Arabinon yields on hydrolysis arabinose alone (O'Sullivan, *C. J.* 1890. 59).

**Preparation.**—A dextrorotatory gum, or one yielding little mucic acid when oxidised by nitric acid, is selected. A solution containing 30–40 g. per 100 c.c. is heated to 100° in a water bath and digested at that temperature with 2 p.c. sulphuric acid for 10–15 minutes. The solution is then cooled, neutralised with milk of lime, baryta water, or calcium or barium carbonate, and hot alcohol, S.G. 0.83, added as long as a precipitate is formed. The clear alcoholic solution is poured off the pp. which in a short time collects at the bottom, and evaporated in a vacuum to a syrup. After standing a few hours arabinose crystallises out in well-formed rhombic prisms with monoclinic terminations, and is purified by recrystallisation from water.

**Formula and synthesis.** See general part.

**Properties.**—Arabinose crystallises in fine rhombic prisms out of aqueous solution. The termination and habitat of the crystals vary with the source. From alcoholic solutions it separates in sphenoids. The crystals melt at 160°. Its specific rotatory power is  $[\alpha]_D = +104.5^\circ$  for 10 p.c. solution at 20°C.; in more concentrated solutions it is higher,  $[\alpha]_D = +110^\circ$  being observed for nearly saturated solutions. Freshly-prepared solutions possess bi-rotation, an angle of  $[\alpha]_D = 156.7^\circ$  having been observed (Scheibler, *l.c.*; O'Sullivan, *l.c.*; E. O. v. Lippmann, *l.c.*; Bauer, *L. V.* 36, 304; Tollens, *A.* 257, 160; Groth, *B.* 6, 615; Griess a. Harrow, *B.* 20, 3111). The specific gravity of aqueous solutions does not increase regularly with the strength, being less in proportion for high concentrations than for low ones. The S.G. of a solution containing 10 g. in 100 c.c. at 15.5° is 1.0385–1.0384.

**Action of acids.** The action of boiling dilute mineral acids destroys much of the opticity and K. of arabinose in a short time (O'Sullivan, 1884, 55). The first products of the change have not been studied. When, however, the action is continued for a considerable time, no *l*ævulinic acid is produced, but fufural is present in large quantities (Ganz, Stone, a. Tollens, *B.* 21, 2148; 23, 3791). Chalmont a. Tollens (*B.* 24, 694) obtained 52.7 p.c. fufural by precipitating the distillate from the products of action of acids with phenylhydrazine acetate. Formic and aceto-propionic acids and humus substances are also present (Conrad a. Guthzeit, *B.* 18, 2905).

**Reduction.**—Treated with sodium-amalgam in acid solutions, arabinose yields *arabitol*, a body resembling sorbitol, m.p. 102°. This body

does not reduce Fehling's solution, and is optically inactive (Kiliani, *B.* 20, 1239).

**Oxidation.**—By oxidation with nitric acid arabinose yields *arabonic acid* (levorotatory trioxylglutaric acid), and by violent oxidation at an elevated temperature oxalic acid (Kiliani, *B.* 21, 3006). Bromine also oxidises it to arabonic acid  $C_5H_8O_6$ , m.p.  $89^\circ$  (Bauer, *J. pr.* [2] 34, 47; *C. C.* 1877, 732; Kiliani, *B.* 19, 3031; 20, 345). It is oxidised by alkaline solutions of metallic oxides, 100 c.c. of Fehling's solution being reduced by 0.4303 g. arabinose, and 100 c.c. of Sachsse's solution being reduced by 0.4375 g. arabinose (Bauer, *L. V.* 36, 304). Its  $K = 108.110$  (O'S., *l.c.*), i.e. 100 pts. of it reduce as much CuO as 108.110 pts. dextrose.

**Fermentation.**—Arabinose does not seem to be capable of fermentation with yeast (Stone a. Tollens, *l.c.*; Scheibler, *l.c.*; v. Lippmann, *B.* 17, 2238); with *Dacillus ethaceticus* it ferments with the production of ethyl alcohol, acetic, formic, and carbonic acids, and hydrogen (Frankland a. MacGregor, *C. J.* 1892, 737).

**Compounds with cyanogen.** By the nitrile reaction arabinose yields a mixture of *l*-gluconic and *l*-mannonic acids (Kiliani, *B.* 19, 3029; 20, 282, 339, 2710; Fischer, *B.* 23, 2611; 24, 639). The first product of the action of HCN on arabinose seems to be a compound of both bodies. HCl converts this into a crystalline amide  $C_5H_7NO_5$ , which on treatment with baryta yields the acids just mentioned.

**Hydrazine compounds.** Arabinose yields with phenylhydrazine, just as dextrose (*q.v.*) does, an osazone, m.p.  $157^\circ$ – $158^\circ$  (Scheibler, *B.* 17, 1729; Kiliani, *B.* 20, 345).

**Compounds with diamines.** With *o*-diamidobenzene, arabinose yields arabinose-*o*-diamidobenzene  $C_5H_4(NH)_2C_5H_4O_5$ . It is a neutral body, not reducing Fehling's solution, and is dextrorotatory, m.p.  $235^\circ$  with decomposition; it withstands boiling with dilute hydrochloric acid or potash, and yields a hydrochloride and hydrobromide. Arabinose-*m*-*p*-diamido-toluene  $C_5H_4(CH_3)(NH)_2C_5H_4O_5$ , m.p.  $238^\circ$ , and arabinose- $\gamma$ -diamido-benzoic acid  $COOH.C_6H_4(NH)_2C_5H_4O_5 + 2H_2O$ , m.p.  $235^\circ$ , have also been obtained (Griess a. Harrow, *B.* 20, 3111). Arabinose gives colour reactions with orcinol and phloroglucinol (Wheeler a. Tollens, *A.* 254, 314; 260, 304).

**Ribose.** Fischer a. Piloty, *B.* 24, 4214.

When certain carboxylic acids of the sugar group are heated with quinoline or pyridine, they are converted with stereo-isomeric acids.

When arabonic acid  $OH.CH_2(CH.OH)_3.COOH$  is treated in this manner it yields a new acid  $COOH.(CH.OH)_3.CH_2OH$ , which the authors name *ribonic acid*; ribonic lactone crystallises from solution in ethyl acetate in long prisms, m.p.  $72^\circ$ – $76^\circ$ , does not reduce Fehling's solution, and is easily soluble in water, alcohol, and acetone. Its specific rotatory power is  $[\alpha]_{D^{20}} = -18$ . Its phenylhydrazide forms colourless needles, m.p.  $162^\circ$ – $164^\circ$ . Ribonic acid may be converted into arabonic acid by heating with quinoline.

By reducing ribonic lactone with sodium-amalgam, it yields the new sugar *ribose*, which forms a phenylhydrazide crystallising from alcohol in colourless crystals, m.p.  $154^\circ$ – $155^\circ$ ; *ribose-osazone* is identical with *arabinose-*

*osazone*. By oxidation ribonic acid yields tri-oxy-glutaric acid, which differs from the tri-oxy-glutaric acid obtained by the oxidation of xylose, but which is also optically inactive. By the further reduction of ribonic lactone, a pentahydric alcohol was obtained which has been found to be identical with the naturally occurring adonitol, obtained from *Adonis vernalis* (Fischer, *B.* 26, 636).

**Xylose.**  $C_5H_{10}O_5$ . It does not occur free in nature.

**Formation.**—It is obtained by the action of dilute boiling acids on xylan or wood gum (Koch, *B.* 20, ref. 145; Wheeler a. Tollens, *B.* 22, 1046; A. 260, 289; Winterstein, *H.* 17, 381; Stone a. Test, *Am.* 15, 195), on the carbohydrate from the epidermis of *Psyllium gallicum* (Bauer, *A.* 248, 140), on vegetable amyloid (Winterstein, *Z. P. C.* 17, 353), on brewer's grain (Stone a. Tollens, *A.* 249, 227; 271, 55), on jute (Wheeler a. Tollens, *l.c.*), and other vegetable bodies (Voswinkel, *C. C.* 1891, 2, 655; Hebert, *Ann. Ag.* 16, 358; 18, 261; Stone a. Lotz, *B.* 24, 1657; Allen a. Tollens, *B.* 23, 137; Bertrand, *Bl.* [3] 5, 554).

**Preparation.**—Xylose may be prepared by extracting straw or any other of the above-mentioned materials by 5 p.c. soda, precipitating the wood gum from the solution by alcohol, and hydrolysing this by boiling with dilute sulphuric acid. The digested solution is treated in the same way as described in the case of arabinose, and the xylose may be easily purified by crystallisation from water.

The formula and synthesis have already been discussed in the general part.

**Properties.**—Xylose is easily soluble in water; 100 pts. of water at  $20.3^\circ$  dissolve 117 pts. of xylose; it is insoluble in absolute alcohol, 90 p.c. alcohol will dissolve in 10 c.c. 0.4 g. sugar at  $19^\circ$  (Bertrand, *Bl.* [3] 7, 499). Its solutions are optically active, freshly-prepared solutions having about four times the constant optical activity (Pareus a. Tollens, *A.* 207, 160). For a 10 p.c. solution at  $20^\circ$   $[\alpha]_D = +19.3^\circ$  (Pareus a. Tollens, *l.c.*; Bertrand, *l.c.*). Schulze a. Tollens (*A.* 271, 40) give the formula  $[\alpha]_D = +18.095 + 0.06986p$  at  $15^\circ$ – $20^\circ$ , where  $p$  = percentage of xylose in solution. Xylose frequently crystallises in prisms belonging to the ortho-rhombic system. Its solutions are not fermentable by yeast. It reduces Fehling's solution,  $K = 109.6$ , agreeing in this respect very closely with arabinose (Bertrand, *l.c.*). Boiled with acids it yields about 50 p.c. furfural (Günther a. Tollens, *B.* 23, 1751; Chalmont a. Tollens, *B.* 24, 694; Bertrand, *l.c.*).

It is reduced by sodium-amalgam to a pentahydric alcohol xylitol (Bertrand, *Bl.* [3] 5, 554; Fischer a. Stahel, *B.* 24, 528). It is oxidised by bromine to xylonic acid (Bertrand, *l.c.*; Allen a. Tollens, *A.* 260, 306); it is oxidised by nitric acid to inactive tri-oxy-glutaric acid  $C_5H_8O_6$  (Fischer, *B.* 24, 1836). By the nitrile reaction xylose yields *l*-gulonic acid, the stereo-isomeride of *l*-gluconic acid (Fischer a. Stahel, *B.* 24, 528; Fischer, *B.* 23, 2625; Fischer a. Curtis, *B.* 25, 1025).

With phenyl hydrazine it yields an *osazone*, m.p.  $160^\circ$ . Warmed with phloroglucinol and hydrochloric acid, it gives a cherry-red coloura-

tion, just as arabinose does under the same conditions (Tollens a. Mayer, *B.* 21, 3508; Wheeler a. Tollens, *B.* 22, 1046).

**Rhamnose.** *Isodulcitol*, *rhamnodulcitol*  $C_6H_{12}O_5 \cdot H_2O$ .

**Preparation.**—Rhamnose is obtained, together with other bodies, by the action of hot dilute acids on quercitrin, hesperidin, xanthorhamnin, naringin, and frangulin (Rayman a. Kruis, *Bl.* [2] 48, 632; *C. C.* 1888, 6; Hlasiwetz a. Pfandler, *A.* 127, 362; Liebermann a. Hörmann, *A.* 196, 323; Kruis, *A.* 196, 333; Berend, *A.* 196, 328; Rigaud, *A.* 90, 292; Will, *B.* 18, 1316; 20, 297 and 1186; Dehn, *Zeit. d. Ver.* 15, 562; Rayman, *Bl.* [2] 47, 668; Tanret, *Bl.* 49, 20; Thorpe a. Miller, *C. J.* 1892, 8).

**Properties.**—Rhamnose forms fine crystals, which have a sweet taste, and a composition corresponding to the formula  $C_6H_{12}O_5 \cdot H_2O$ ; by careful drying it loses water and then melts at  $90^\circ$ – $110^\circ$  (Websky, *B.* 18, 1318; Hirschwald, *A.* 196, 330). It is easily soluble water, and its solutions are dextrorotatory,  $[\alpha]_D = +9^\circ$ . Freshly-prepared solutions show bi-rotation (Schnelle a. Tollens, *A.* 271, 61). In alcoholic solutions the optical activity decreases as the proportion of alcohol to water increases, until the solution becomes levorotatory (Rayman a. Kruis, *C. C.* 1889, 6). It reduces Fehling's solution, 1 c.c. being reduced by 0.0052–0.0055 g. rhamnose ( $K = 91$ –91) (Rayman a. Kruis, *l.c.*). Its solution does not ferment with yeast.

**Action of acids.** Boiled with moderately strong acids furfural is evolved (Maquenne, *C. R.* 109, 603). Concentrated nitric acid converts it into a nitrate.

**Oxidation.**—Nitric acid oxidises rhamnose to tri-oxo-glutaric acid (Will a. Peters, *B.* 22, 1697). Malin (*A.* 145, 197) obtained an acid  $C_6H_{10}O_8$ . Bromine water oxidises it to rhamnonic acid  $C_6H_{10}O_8$ , which is obtained in the form of the lactone  $C_6H_{10}O_5$ , m.p.  $148^\circ$  (Will a. Peters, *B.* 21, 1813; Rayman, *B.* 21, 2046). With bromine and silver oxide it is oxidised to acetaldehyde and acetic acid (Herrig, *Chem. Zeit.* 1887, Rep. 145; *M. S.* 2, 227).

**Reduction.**—Sodium-amalgam reduces rhamnose to rhamnitol  $CH_2(OH)(CH_2OH)_4CH_2OH$ , which crystallises from alcohol or acetone in triclinic prisms, m.p.  $121^\circ$ , and has a sweet taste (Fischer a. Piloty, *B.* 23, 3102).

**Compounds.**—With phenylhydrazine rhamnose yields a hydrazone  $C_6H_5 \cdot O \cdot N_2HC \cdot H_2$ , m.p.  $159^\circ$ , and an osazone  $C_6H_5 \cdot N_2O_3$ , m.p.  $180^\circ$  (Will, *B.* 20, 1186; Fischer a. Tafel, *B.* 20, 1089, 1091 a. 2566). With aniline it forms a compound  $C_6H_5 \cdot O \cdot NC \cdot H_2$ , m.p.  $118^\circ$  (Rayman a. Kruis, *l.c.*). With ammonia and ethylacetate it forms rhamnodiasine  $C_6H_{10}O_5 \cdot N_2$ , m.p.  $186^\circ$  (Rayman a. Chodounsky, *B.* 22, 304 and 3247).

Rhamnose combines with hydrocyanic acid to produce rhamnonamide. The lactone  $C_6H_{10}O_5$  crystallises in needles, melting-point  $168^\circ$ ; this is reduced by hydriodic acid and phosphorus to normal heptioic acid (Fischer a. Tafel, *B.* 21, 1657 a. 2173). Rhamnose hexoic acid lactone is reduced by sodium-amalgam to a sugar (Fischer, *B.* 22, 2204; Fischer a. Tafel, *B.* 23, 8102). Sodium rhamnose  $C_6H_{11}O_5Na$  is precipitated by adding sodium ethylate to an alcoholic solution of rhamnose (Liebermann a.

Hamburger, *B.* 12, 1186). With benzoyl chloride tri- and tetra- rhamno-benzoates are formed; with acetic anhydride rhamno-tetracetate (Rayman, *B.* [2] 47, 668). From thermo-chemical considerations rhamnose appears to be methylxylose (Stohmann a. Langbein, *J. pr.* [2] 45, 806).

\* **Fucose**  $C_6H_{12}O_5$  is obtained by the hydrolysis of fucus. The sugar forms microscopic needles. Its solution has a sweet taste and is levorotatory,  $[\alpha]_D = -77^\circ$ . With phenyl-hydrazine it forms a hydrazone, melting-point  $170^\circ$ , and an osazone, melting-point  $159^\circ$  (Bieler a. Tollens, *A.* 258, 110; Günther a. Tollens, *B.* 23, 2585). Fucose appears to be methyl-arabinose (Stohmann a. Langbein, *l.c.*).

**Dextrose.** *d-glucose, glucose, starch-, corn-, grape-, honey-, diabetic sugar.* (Ger. Krimmelzucker, Traubenzucker; Fr. Sucre de raisin.)  $C_6H_{12}O_6$  and  $C_6H_{12}O_5 + H_2O$ .

**Occurrence.**—Dextrose is widely distributed throughout the vegetable kingdom, being usually accompanied by levulose and cane sugar. The most important sources are honey, most fruits, the sap of plants, seeds. It occurs in the animal kingdom in the liver, blood, and other parts of the body, and in diabetic urine (S. Sachsse, *Die Ch. und Phys. der Farbst. Kohlenhydrate u. Protein subst.*, Leipzig, 1877; F. Maack, *J.* 1860, 892; Girard, *B.* 17, 17c; Neubauer, *Fr.* 12, 39; Gorup-Besancz, *B.* 4, 906; Petit, *B.* 6, 1313; v. Schneider, *A.* 162, 235; Report on Sorghum and Cornstalks, Dep. of Agr., Report No. 35, Washington, 1881; Hermann a. Tollens, *A.* 230, 50; Vogel, *B.* 15, 2271; Fischer a. Bödecker, *A.* 117, 111; De Bary, *Hoppe-Seyler's Medic. Ch. Unt.* p. 72; Hoppe-Seyler, *Handb. d. phys. Ch. Ana.*, 1883, 301; Klason, *B.* 19, 2541; Wehmer, *Inaug. Diss.*, Göttingen, 1886, 40; O'Sullivan, *C. J.* 1886, 58; Wehmer a. Tollens, *B.* 19, 707; Seegen a. Kratzschmer, *Pf.* 22, 206; Kütz, *Pf.* 24, 62; Boussingault, *C. R.* 91, 639; J. Sieben, *B. C.* 1885, 134; Hermann a. Tollens, *A.* 230, 50; Müller, *Ann. Agronom.* 13, 88; Seegen, *Pf.* 37, 348; 39, 121; 40, 48; Cuisinier, *C. C.* 1886, 614; H. Thoms, *B.* 21, 1916a; Reali, *G.* 17, 325; Maquenne, *A. Ch.* [6] 17, 495).

**Formation.**—By the action of acids and ferments on the following glucosides: amygdalin (Schmidt, *A.* 119, 92; Hesse, *l.c.*, 176, 112); populin (v. Lippmann, *B.* 12, 1648b); ruberythric acid (Liebermann a. Bergami, *B.* 20, 2247); salicin (Schmidt, *A.* 119, 97; Hesse, *l.c.*, 176, 112); lupinin (*B.* 11, 2200b); hesperidin (Tanret, *Bl.* 49, 20); phlorizin (Rennie, *C. J.* 1887, 636). Other glucosides yield dextrorotatory, reducing, fermentable, and crystallisable sugars, but there is not sufficient evidence to prove with certainty that they are dextrose. These are: asculin (Rochleder a. Schwarz, *A.* 87, 186; Zwenger, *l.c.*, 90, 76); arbutin (Hlasiwetz a. Grabowski, *Ar. Ph.* 141, 329); coniferin (Tiemann a. Harmann, *B.* 7, 608).

By the action of dilute acids the following carbohydrates yield dextrose, alone or with other glucoses. Some of them are also hydrolysed to dextrose by ferments:

$\alpha$ - and  $\beta$ -amylan yield dextrose.

Cellulose yields dextrose (Flechaig, *H.* 7, 523;

Lindsay a. Tollens, *A.* 267, 870).

Glycogen yields dextrose.

**Lichenin yields dextrose.**

Tunicin "

Starch "

Dextrin "

Maltose "

Lactose yields dextrose and galactose.

Cane sugar yields dextrose and levulose.

Raffinose yields dextrose, levulose, and galactose.

**Preparation.**—Dextrose can be prepared from any of the substances above mentioned, but it is in many cases difficult to obtain it in any quantity in the pure state. Starch and sucrose are the bodies usually employed, and we find that lactose can also be used with advantage.

(a) A white saccharum (the commercial glucose obtained by the action of acids on starch) with an optical activity approaching that of dextrose is selected. This is scraped as fine as possible, and treated with boiling ethyl alcohol S.G. .820. On cooling, the clear saturated solution is separated from the undissolved syrup and a little previously prepared dextrose added to it. Crystallisation soon begins and continues for some time; a crop of fairly pure dextrose is thus obtained. Further purification can be effected by melting the crystals in 8-10 p.c. boiling water and adding dry boiling methyl alcohol until a slight cloud is produced. Anhydrous dextrose in a state of great purity separates abundantly from this solution. Or the saccharum is melted in 5 or 6 p.c. water, allowed to crystallise, the crystals pressed and further purified by treatment with methyl alcohol as described.

(b) A 25 p.c. aqueous solution of crystallised sucrose is taken and heated to 50°-55° and 2-3 p.c. pressed brewers' yeast stirred in (Tompson, *E.P.* 8686, 1884), the temperature is maintained for 2-3 hours, when the sucrose is completely inverted—that is, converted into dextrose and levulose. The solution is then evaporated in a vacuum to a syrup, S.G. 1.5 or thereabouts. On standing for a short time this solidifies to a crystalline mass; it is washed with cold alcohol, S.G. .830, and the residue dissolved to saturation in alcohol of the same strength. Dextrose soon begins to crystallise out; the crystals can be further purified by dissolving in methyl alcohol and recrystallisation.

Sucrose may also be inverted by digestion with sulphuric acid, the acid separated by baryta water, and the filtrate from the barium sulphate evaporated to a syrup and treated in the way mentioned. Inversion by yeast yields the best result. Soxhlet (*J. pr.* [2] 21, 242) recommends that inversion be effected by alcoholic hydrochloric acid. 480 c.c. of strong hydrochloric acid are mixed with 12 litres of alcohol, S.G. .810, in a glass vessel, the mixture heated 45°-50°, 4 kilos. powdered sucrose stirred in, and the whole maintained at that temperature for two hours. When cool a little previously prepared anhydrous dextrose is added, and in a few days there is an abundant crystallisation of dextrose. This can be purified by crystallisation from methyl alcohol. Should any colour be developed, the aqueous solution is treated with animal charcoal and again concentrated in a vacuum. Under such circumstances it is better to begin again, for if proper care be taken no colour need be produced.

An aqueous solution containing 25 p.c.

lactose and 8 p.c. sulphuric acid is digested in a water-bath for three hours, care being taken by continued agitation that no colour is developed, the sulphuric acid is separated by baryta water, and the filtrate concentrated to a syrup containing 76-80 p.c. solid matter. On standing this solidifies, and after a few days is treated with boiling methyl alcohol; this dissolves out the dextrose, leaving the galactose undissolved; the former soon crystallises from the saturated methyl alcohol. A recrystallisation yields the pure body in moderately large, well-defined crystals.

Hydrous dextrose  $C_6H_{12}O_6 \cdot H_2O$  can be obtained from any of the above preparations by dissolving in 12 to 20 p.c. water, and allowing to crystallise. If honey is used as a source of dextrose, any sucrose it may contain should be inverted by yeast or acids, and the residue obtained by evaporation crystallised from methyl alcohol as in the case of inverted sucrose. A pure product may be obtained in a few crystallisations.

**Formula and synthesis.** See first part on the sugars generally.

**Properties.**—Dextrose crystallises out of 93-95 p.c. ethyl or methyl alcohol in the anhydrous state. Anhydrous crystals may also be obtained by special treatment from concentrated aqueous solutions at 30°-35°. As a rule aqueous solutions deposit crystals containing one molecule of water of crystallisation. Anhydrous dextrose crystallises in rhombic, hemiedric forms; the axial relationship is  $a:b:c = 0.704:1:1.335$ . Hydrated dextrose forms hemimorphous crystals; the elements are  $a:b:c = 1.7350:1.19080, \beta = 97^\circ 59'$  (F. Becke, *M.* 10, 231). Well-defined crystals of both varieties are difficult to obtain; usually the first separates as a powder and the second in cauliflower-like masses; both dissolve easily in water, the first with evolution of heat. Hydrated dextrose dissolves easily in strong ethyl and methyl alcohol, but the anhydrous sugar is almost insoluble in them. It is insoluble in ether and hydrocarbons, slightly soluble in aniline, acetic acid, and acetic ether. Hydrated dextrose easily loses its molecule of water of crystallisation when exposed in a vacuum over sulphuric acid, or when heated gently. The anhydrous sugar melts at 144°-146° (Hesse, *A. Ch.* 176, 106); its specific gravity is, according to Guérin-Varry a. Heintz, 1.386; according to Bödecker, 1.5384 (v. Lippmann, *Zuckerarten*, p. 12). Dextrose is not so sweet as cane sugar. Behr (*B.* 15, 1106) finds it  $\frac{2}{3}$  as sweet, and T. Schmidt (*B.* C. 1887, 405) that 1.53 pts. of dextrose are as sweet as 1 part of cane sugar. An aqueous solution of 10 g. dry dextrose in 100 c.c. of solution at 17.5° has a specific gravity of 1.0381 (water at 17.5-1) (Salomon, *B.* 14, 2710). This is fairly accurate,  $K = 100$ . Its solutions rotate the plane of polarisation of a ray of polarised light to the right. According to Hesse a. Tollens (*B.* 17, 2234), the amount of rotation for the D line is expressed by the formula  $[\alpha]_D = 52.5 + .018796P + .00051683P^2$  for anhydrous dextrose, and  $[\alpha]_D = 47.73 + .015584P + .0003888P^2$  for hydrated dextrose, in which P is the percentage of the two varieties respectively in solution. In solutions containing 10 p.c. dry sugar and thereabouts, the

factors  $[\alpha]_D = 53.7$  and  $[\alpha]_D = 58.8$  are sufficiently accurate, but probably a shade too low. These values are not materially affected by the temperature. The presence of some inactive bodies in the solution appears to have some effect (Pribram, *M.* 9, 895); bodies such as potash, soda, lime, &c., which act on dextrose reduce its optical activity; other bodies, such as urea, do not alter it (N. Wender, *B.* 24, 2200). Freshly-prepared solutions have a greater optical activity than those which have stood a few hours. F. Urech (*B.* 17, 1547) has observed a rotation 2.19 times greater than the constant value. Parcus a. Tollens (*A.* 257, 160) observed an angle of  $[\alpha]_D = 105.16$  in a 10 p.c. solution 5½ min. after commencing solution. This phenomenon is called *bi-rotation*; the optical activity quickly falls, and the constant value is reached in about six hours in the cold and immediately on boiling. The bi-rotation is also immediately destroyed by potash (O'Sullivan a. Tompson, *C. J.* 1890, 920), or ammonia (Schulze a. Tollens, *A.* 271, 49). Dextrose when produced by the inversion of cane sugar at a low temperature is set free in the bi-rotatory state (O'Sullivan a. Tompson, *l.c.*). Only crystallised dextrose exhibits this phenomenon; fused dextrose does not show it (Hesse, *A.* 176, 113). A solution of dextrose in strong alcohol retains its bi-rotation (?) The dispersive power of dextrose solution is practically the same as that of quartz (Hoppe-Seyler, *Pr.* 3, 1866, 412). The ratio between the specific rotatory power for the C and D lines respectively is 1:1.258 (Grimbert, *J. Ph.* [5] 16, 295 and 345). The heat of combustion of dextrose is +677.2 cal., and the heat of formation +300.8 cal. (Berthelot a. Recoura, *C. R.* 104, 1571).

**Action of heat.** When the dry sugar is heated to 170°, a molecule of water is eliminated and dextrosan  $C_6H_{10}O_5$  is produced, which may be reconverted into dextrose by the action of water and dilute acids. If the temperature is raised to 200°, gas, water, and volatile acids are given off, and if the heating be continued without raising the temperature, a brownish black mass is finally left. This substance is soluble in water and constitutes the colouring matter (caramel) used in beer, wine, cooking, &c. Should the temperature be raised, carbon monoxide, dioxide, and methane are evolved, and aldehyde, furfural, acetone, metaacetone, propionic, acetic, and formic acids distil over, and a black carbonaceous mass is left. If the hydrate be heated for a considerable time in a closed tube a fluid is obtained which absorbs oxygen and nitrogen (?) from the air (Thénard, *C. R.* 52, 795).

**Action of acids.** Dextrose is dissolved by strong sulphuric acid without blackening, dextrose-sulphuric acid being formed (Péligot, *A. Ch.* [2] 67, 170); from this solution alcohol precipitates a compound of diglucose with alcohol (Musculus a. Meyer, *B.* 14, 850). Similar compounds are produced by the action of chlorosulphuric acid (Clæsson, *J. pr.* [2] 20, 1). A mixture of sulphuric and nitric acids converts dextrose into a nitro-compound (Carey Lea, *Bl.* [2] 10, 415). Dextrose phosphoric acid is said to exist (Amato, *B.* 4, 418). Several acetyl derivatives have been described. Dextrose diacetate  $C_6H_{14}O_7(C_2H_3O_2)_2$  and dextrose triacetate

$C_6H_9O_4(C_2H_3O_2)_3$  are amorphous, soluble in water, alcohol and ether (Schützberger a. Naudin, *Bl.* [2] 12, 107, 204; Liebermann a. Hörmann, *B.* 11, 1619; Herzfeld, *B.* 13, 265). Dextrose pentacetate  $C_6H_5O_2(C_2H_3O_2)_5$  is prepared by the action of acetic anhydride and zinc chloride on dextrose, m.p. 111–112 (Erwig a. Koenigs, *B.* 22, 1464, 2207). Didextrose octoacetate  $C_{12}H_{21}O_8(C_2H_3O_2)_8$  is prepared by the action of acetic anhydride and sodium acetate on dextrose, m.p. 184 (Herzfeld a. Erwig a. Koenigs, *l.c.*). Dextrose-monochlorhydrin-tetracetate is formed by the action of acetyl chloride on dextrose (Culley, *C. R.* 70, 401). Tri-, tetra-, and penta-benzyl  $(C_6H_5(C_2H_4O)_n)$  dextroses are obtained by the action of benzoic chloride and potash on dextrose (Skraup, *M.* 10, 389; Kucny, *H.* 14, 330; Panormioff, *J. R.* 23, 375). Compounds of dextrose with other organic acids have been prepared (Berthelot, *A. Ch.* [3] 54, 74; *Gm.-K.* 7, 764; v. Lippmann, *Zuckerarten*, p. 40; Baumann, *B.* 19, 3218; Colley, *C. R.* 76, 436). If dextrose is boiled with dilute sulphuric acid the specific gravity of the solution gradually increases for some time, apparently from the fixation of the elements of water. On continued boiling the solutions become coloured, brown humus substances, aceto-propionic and formic acids, are produced (Malaguti, *A. Ch.* [2] 59, 407; Tollens a. Grote, *A.* 175, 181; 206, 207; Wohl, *B.* 23, 2084). Dilute hydrochloric acid produces similar results, but more rapidly. Gummy bodies are also produced (Grimaux a. Lefèvre, *C. R.* 103, 146). See also Conrad a. Guthzeit (*B.* 18, 439; 19, 2569) and Wehmer a. Tollens (*B.* 19, 707).

**Action of alkalis.** Alkalis give a brownish colour with dextrose solution, quickly on heating, slower in the cold, with production of acetal, acetone, and lactic, acetic, and formic acids. Other bodies of unknown composition are also formed, such as glucinic, saccharumic and japonic acids. When potash is used oxygen is absorbed. With calcium hydroxide, saccharin or calcium saccharinate is also produced; this is not one of the products of the action of potash (Emmerling a. Loge, *B.* 14, 1005; 16, 838; Henry, *B.* 14, 2272; Breuer a. Zincke, *B.* 13, 638; Rochleder a. Kawalier, *J. pr.* 94, 403; Hoppe-Seyler, *B.* 4, 346; Kiliani, *B.* 15, 700; Nencki a. Sieber, *J. pr.* [2] 24, 498; Péligot, *A. Ch.* 30, 75; Mulder, *A. Ch.* 36, 260; Reichardt, *Z.* 1870, 401; v. Lippmann, *Zuckerarten*, p. 22; Péligot, *B.* 13, 196; Scheibler, *B.* 13, 212; Kiliani, *B.* 15, 701; Cuisinier, v. Lippmann, *Zuckerarten*, p. 25; Scheibler, *B.* 16, 2434). Thénard (*C. R.* 52, 444) obtained bitter bodies containing 10–19 p.c. nitrogen, by acting on dextrose with ammonia; they absorb oxygen from the air, and resemble certain nitrogenous humic acids. Tanret (*Bl.* [2] 44, 102) obtained two volatile bases:  $\alpha$ -glucosine  $C_6H_{11}N$ , b.p. 136° and  $\beta$ -glucosine  $C_6H_{11}O_5$ , b.p. 160°, by heating dextrose with strong ammonia. Heated with aniline, dextrose anilide is produced (Schiff, *A.* 140, 123; Sorokin, *B.* 19, 298).

**Reduction.**—Nascent hydrogen reduces dextrose in alkaline solutions to mannitol, but not in neutral or acid solutions (Linnemann, *A.* 128, 186; Dewar, *Z.* 1870, 418; Bouchardat, *Bl.* [2] 16, 88; Krusemann, *B.* 9, 1466). Under the most

favourable conditions the yield does not exceed 10 p.c. If the reduction be carried on at a high temperature other fatty alcohols are formed. Meunier (*C. R.* 111, 49) obtained sorbitol by reducing dextrose with sodium-amalgam.

**Oxidation.**—Gluconic acid  $C_6H_{12}O_7$  is produced by oxidising dextrose with mercuric oxide (Heffter, *B.* 22, 1049; Herzfeld, *A.* 245, 27) or with chlorine or bromine and subsequent treatment with silver oxide (Hlasiwetz a. Habermann, *A.* 155, 122; 156, 253; Kiliani, *A.* 205, 182; Kiliani a. Kleeman, *B.* 17, 1298; Herzfeld, *A.* 220, 335, 358), or by the action of *Bacterium aceti* (Brown, *C. J.* 1886, 179; Bouteux, *C. R.* 1880, 236). Oxygen has no action on dextrose in neutral or acid solutions, but it is absorbed by alkaline solutions. Ozone oxidises dextrose to saccharic and formic acids (Renard, *A. C.* 5, 17, 289). Platinum black acts similarly (Loew, *B.* 23, 865). Nitric acid oxidises dextrose to saccharic acid  $C_6H_{10}O_8$ , and finally to oxalic, formic, and carbonic acids (Liebig, *A.* 113, 1; Heintz, *P.* 51, 183; Hornemann, *J. pr.* 89, 304; Kiliani, *A.* 205, 172; Guérin-Varry, *A.* 8, 81; Sohst a. Tollens, *Z.* 11, 99). Iodine when acting on alkaline solutions of dextrose yields a little iodoform (Lieben, *A. Suppl.* 7, 228; Hermann a. Tollens, *B.* 18, 1335; Millon, *C. R.* 21, 828). Alkaline solutions of many metallic oxides oxidise dextrose, in some cases being reduced to the metal, in others to lower oxides. Potassium ferrocyanide, potassium permanganate, indigo, picric acid, litmus, &c., oxidise dextrose also. The chief products are formic, oxalic, glycollic, and carbonic acids. Some of these reactions are employed for the quantitative estimation of dextrose (Tollens, *B.* 16, 921; Herzfeld, *Zeitschr. d. Ver. d. Rübenzucker-Ind.* 37, 337; Habermann a. Hönig, *B.* 15, 2624; Worm-Müller a. Hagen, *Pf.* 22, 325; *B.* 13, 2096 a. 2442; Herzfeld a. Bruhns, *Zeitschr. d. Ver. d. Rübenzucker-Ind.* 36, 110; Reichardt, *A.* 127, 297; Felsko, *A.* 149, 356; Beyer, *A.* 131, 353; Claus, *A.* 147, 115; Smolka, *B.* 20, 167; *M.* 8, 1).

**Fermentation.**—Under the influence of various species of saccharomyces and other organisms, dextrose ferments, yielding alcohol and carbon dioxide as the chief products, glycerol, succinic acid, and small quantities of other bodies are formed at the same time. Bacteria decompose dextrose in other ways, one yielding chiefly lactic acid, another butyric, another cellulose, &c. (*v. FERMENTATION*).

**Compounds with acids (v. Action of acids).**

**Compounds with bases.** Potassium and sodium dextrose  $C_6H_{11}KO_6$  and  $C_6H_{11}NaO_6$  are prepared by adding potassium or sodium ethylate to a solution of dextrose in strong alcohol. A white, bulky precipitate is obtained, which is very hygroscopic, and decomposed by water (Hönig a. Rosenfeld, *B.* 10, 871; Franchimont, *B.* 10, 994). The compounds with the alkaline earths are differently constituted, being apparently a combination of the sugar and base. They are formed by mixing alcoholic solutions of the base and sugar, or by precipitating their mixed aqueous solutions with alcohol. Lime forms  $C_6H_{11}O_6 \cdot CaO \cdot H_2O$ ,  $C_6H_{11}O_6 \cdot CaO$ ,  $2C_6H_{11}O_6 \cdot 3CaO \cdot H_2O$ ,  $2C_6H_{11}O_6 \cdot 3CaO \cdot 2H_2O$ ,  $4C_6H_{11}O_6 \cdot 8CaO$ , and similar compounds are

formed with baryta, strontia, and magnesia. Neither lead acetate nor subacetate precipitate aqueous dextrose solutions, but lead oxide yields compounds similar to those with lime &c. (Brendeche, *Ar. Ph.* [2] 29, 84; v. Lippmann, *Zuckerarten*, p. 45; Péligot, *J. pr.* 15, 105; Franchimont, *B.* 12, 1939). Alkaline dextrose solutions dissolve copper hydroxide, and from these solutions soda or potash in proper proportions precipitates compounds of copper oxide and dextrose of varying composition (Guignet, *C. R.* 109, 528; Worm-Müller a. Hagen, *Pf.* 22, 325; Fileti, *B.* 8, 441; Salkowski, *B.* 12, 704). The compound  $C_6H_{11}O_6 \cdot 2ZnO \cdot 3H_2O$  is formed by adding an alcoholic solution of dextrose to an ammoniacal solution of zinc oxide (A. C. Chapman, *C. J.* 1889, 576). Dextrose forms amorphous compounds with nickel, chromium, and iron oxides (Chapman, *C. J.* 1891, 323).

**Compounds with metallic salts.** Dextrose forms well-defined crystalline compounds with sodium chloride and bromide; their formulae are  $2C_6H_{11}O_6 \cdot NaCl \cdot H_2O$ , which crystallises from diabetic urine,  $C_6H_{11}O_6 \cdot NaCl$ ,  $C_6H_{11}O_6 \cdot 2NaCl$ ,  $2C_6H_{11}O_6 \cdot NaBr$  (Pasteur, *A. Ch.* [3] 31, 92; Erdmann a. Lehmann, *J. pr.* 13, 111; v. Lippmann, *Zuckerarten*, p. 45; Städeler, *C. C.* 1854, 930; Hönig a. Rosenfeld, *B.* 10, 872; Stenhouse, *A.* 129, 286).

**Compounds with cyanogen.** By digesting an aqueous solution of dextrose with hydrocyanic acid solution, the following reaction takes place:  $C_6H_{11}O_6 + HCN + 2H_2O = C_6H_{11}O_6NH_2$  (Kiliani, *B.* 19, 767). To prepare this compound Kiliani gives the following directions: 100 g. crystalline dextrose are dissolved in 80 g. water, and an equivalent quantity of 60 p.c. hydrocyanic acid is added and digested for six days at the ordinary temperature; after twenty-four hours' further digestion at 35°C. all smell of hydrocyanic acid had disappeared, and the liquid smelt of ammonia. The ammonium salt thus obtained is converted into a barium one by boiling with baryta, and the free acid obtained by removal of the barium by sulphuric acid. Fischer (*A.* 270, 64) dissolves 5 kilos. dextrose in 25 litres 3 p.c. hydrogen cyanide solution, adds 10 c.c. ammonia solution, and digests the solution at 25°C. for six days, boils with baryta (6.7 kilos.) dissolved in water (20 litres) until all the ammonia is expelled, the hot liquid acidified with sulphuric acid, and boiled to expel hydrogen cyanide, neutralised with baryta, and filtered. The filtrate is concentrated. This syrup contains the lactones of  $\alpha$ -heptonic acid and  $\beta$ -heptonic acid. After standing some weeks nearly the whole of the  $\alpha$ -lactone will have crystallised out; the mass is triturated with alcohol of 80 p.c.; the filtrate yields a further crop of  $\alpha$ -lactone, and the mother-liquor contains the  $\beta$ -lactone. This may be obtained by neutralising with brucine; the brucine  $\beta$ -heptonate crystallises out, and is purified by recrystallisation; the brucine may be separated by precipitation with baryta, and the barium salt decomposed by sulphuric acid.

$\alpha$ -Glucuheptone-lactone forms rhombic crystals readily soluble in water, and has  $[\alpha]_D = -55.3$ ; boiled with concentrated hydriodic acid it yields a heptolactone, b.p. 216°–230° at 171 mm., with partial decomposition. About an equal quantity

of normal heptioic acid is also produced (Kiliani, *B.* 19, 1128). By digestion with nitric acid S.G. 1.2 at 40° for 24 hours,  $\alpha$ -glucoheptioic acid is oxidised to normal penta-oxy-pimelic acid (Kiliani, *B.* 19, 1916); this melts at 143°, is easily soluble in water, difficultly in alcohol, and soluble in ether.  $\alpha$ -Gluco-heptonic acid yields a hydrazide  $C_6H_{11}O_5N_2H_2C_6H_5$ , m.p. 171°–179° (Fischer, *B.* 22, 2732).

$\beta$ -Gluco-heptonic lactone crystallises in delicate needles, m.p. 151°–152°, reduces Fehling's solution, and is very soluble in water; its sp. rot. power is  $[\alpha]_{D_{20}} = -67.7^\circ$ . Its phenylhydrazide  $C_6H_{11}O_5N_2H_2Ph$  crystallises from alcohol in yellowish leaflets, and melts at 150°–152°. Heated with pyridine (4 lactone, 4 pyridine, and 20 water) in a sealed tube for three hours it is converted into the  $\alpha$ -acid.

**Hydrazine compounds.** A concentrated solution of dextrose yields, with phenylhydrazine, dextrose phenylhydrazine  $C_{12}H_{19}N_2O_5$ ; this forms fine crystals, melting at 144°–145°. When heated with an aqueous solution of phenylhydrazine, hydrochloride, and sodium acetate on the water-bath, yellow crystals of phenylglucosazone  $C_{17}H_{25}N_3O_4$  are formed (Fischer, *B.* 20, 824). Phenylglucosazone can be prepared by heating on the water-bath 1 pt. dextrose, 2 pts. phenylhydrazine hydrochloride, 3 pts. sodium acetate, and 20 pts. water; after 10–15 minutes' heating the separation of osazone commences, and after 1½ hours the precipitate amounts to about 85–90 p.c. of the weight of dextrose taken. It is purified by recrystallisation from alcohol. Another method which gives satisfactory results is to heat a mixture containing 1 g. sugar in 100 c.c. water and 5 c.c. of a solution containing in 1 litre 400 g. phenylhydrazine and 400 g. glacial acetic acid. According to Maquenne's (*C. R.* 112, 799) numbers, the yield is low, but by increasing the strength of the sugar solution and keeping up the quantity of the phenylhydrazine acetate solution in proportion, it is materially increased. It is insoluble in water; not very soluble in cold, but fairly easily in boiling alcohol. It melts at 204°–205° with decomposition, and so in m.p. determinations it is important that the heating be done as quickly as possible. It reduces Fehling's solution, and is levorotatory (Fischer, *B.* 17, 579). It dissolves in cold fuming hydrochloric acid, with a dark-red colouration, the osazone group  $C_6H_7HN_2C:C:N_2HC_6H_5$  being thereby converted into the group  $CO.CO$ . This reaction is common to all the osazones of the sugars, and Fischer (*B.* 21, 2631) has called the compounds thus obtained *-osones*. Dextrosone reduces Fehling's solution on boiling, and does not ferment with yeast; with phenylhydrazine acetate it again yields phenylglucosazone. The osazone is reduced by zinc and acetic acid to iso-glucosamine, which yields levulose by treatment with nitrous acid (Fischer, *B.* 19, 1920; 20, 2569). The osone yields compounds with methyl phenylhydrazine and ortho-diamines (Fischer, *B.* 22, 87). By proceeding in the same way *o*-tolyl-dextrosazone  $C_{20}H_{29}N_3O_4$ , m.p. 201° and *p*-tolyl-dextrosazone  $C_{20}H_{29}N_3O_4$  have been prepared (Raschen, *A.* 239, 229). Diphenyl-hydrazine combines with the sugars in alcohol solution; sparingly soluble crystalline hydrazones are

formed, which are resolved into their constituents by concentrated hydrochloric acid. The dextrose compound  $C_{16}H_{21}O_5N_2(C_6H_5)_2$  melts at 161° (Stahel, *A.* 253, 242). Roder (*A.* 236, 229) has prepared phenyl-dextrosazone carboxylic acid.

**Compounds with aromatic amines.** Dextrose-*o*-diamido-benzene  $C_6H_4(NH_2)_2C_6H_5O_5$ , and anhydro-dextrose-*o*-diamido-benzene  $C_6H_4N_2C_6H_5O_5 + 2H_2O$  are formed by the interaction of dextrose and *o*-phenylene-diamine in acid solution. Di-dextrose-*o*-diamido-benzene is obtained when the reaction takes place in neutral solution. They are all crystalline bodies, soluble in water, and having a bitter taste. The first one does not reduce Fehling's solution, the last two do (Griess a. Harrow, *B.* 20, 281 and 2205); *o*-tolylene-diamine gives a similar compound (Hinsberg, *B.* 20, 495). Dextrose- $\gamma$ -diamido-benzoic acid is obtained by mixing boiling aqueous solutions of dextrose and  $\gamma$ -diamido-benzoic acid (Griess a. Harrow, *l.c.*). With aniline dextrose forms a crystalline anilide m.p. 147° (Schiff, *A.* 154, 30; Sorokin, *B.* 19, 513; *J. R.* 1887, 377). Dextrose forms compounds with aldehyde, acetone, benzaldehyde, chloral, &c. (Schiff, *A.* 244, 19; Heffter, *B.* 22, 1050).

**Dextrose-oxim**  $C_6H_{11}O_5N$  is formed by the combination of dextrose and hydroxylamine. It forms colourless, microscopic crystals, m.p. 136°–137°; very soluble in water, sparingly soluble in alcohol, and insoluble in ether. It reduces Fehling, and is levorotatory, having  $[\alpha]_{D_{20}} = -2.2^\circ$  (Jacobi, *B.* 24, 696).

On warming an alkaline solution of dextrose with picric acid a blood-red colour is produced (Braun, *Fr.* 4, 185). If to crystallised diazobenzene sulphonic acid be added soda, dextrose solution, and a little sodium-amalgam, a red colouration is produced in a short time (Penzold a. Fischer, *B.* 16, 657).

Many aromatic alcohols give a colouration with dextrose and other carbohydrates in the presence of sulphuric acid. If two drops of a 15–20 p.c. alcoholic solution of (*a*)-naphthol be added to a dextrose solution, and one part of concentrated sulphuric acid, a violet colouration will be produced, changing to bluish violet.

Optical isomerides of glucose, gluconic acid and saccharic acid (E. Fischer, *B.* 23, 2611).

***l*-Gluconic acid.** *l*-Mannonic acid can be converted into *l*-gluconic acid by heating with quinoline, but it is most conveniently prepared from arabinose by treatment with hydrogen cyanide and baryta (Kiliani, *B.* 19, 3029); *l*-mannonic and *l*-gluconic acids are formed simultaneously. The greater portion of the *l*-mannonic acid may be separated as lactone, and the remainder may be separated from the *l*-gluconic acid by crystallising out the calcium *l*-gluconate.

*i*-Gluconic acid is obtained by mixing the *l*- and *d*-acids, or from *i*-mannonic acid by quinoline.

***l*-Glucose** is formed by reducing *l*-gluconic lactone with sodium-amalgam; it resembles dextrose closely, but does not ferment with yeast;  $[\alpha]_D = -51.4^\circ$ ; its derivatives also resemble the corresponding ones of dextrose very closely.

***i*-Glucose** is prepared by mixing *l*- and *d*-glucose, or reducing *i*-gluconic acid.

**L-Saccharic acid** is prepared by oxidising l-gluconic acid with nitric acid.

**d-Saccharic acid** is prepared by oxidising d-gluconic acid or by mixing l- and d-saccharic acid.

**Lævulose. d-Fructose, lævoglucose, fruit sugar;  $C_6H_{12}O_6$ .**

**Occurrence.**—Lævulose is widely distributed in the vegetable kingdom, being found, together with dextrose, in many parts of plants, in honey, &c. (*v. Dextrose*).

**Formation.**—The following carbohydrates yield lævulose, either alone or accompanied by other sugars, when acted on by dilute acids:

Cane sugar yields dextrose and lævulose.

Raffinose yields lævulose, galactose, and dextrose.

Inulin yields lævulose.

Irisin (O. Wallach, *A.* 234, 364), lævulan (v. Lippmann, *B.* 14, 1509), triticin (Reide-meister, *C. C.* 1880, 808), scillin (Riche a. Remont, *J. Ph.* [5] 2, 291), sinistrin (Schmiede-berg, *B.* 12, 704), lævulin or synanthrose (Dieck a. Tollens, *A.* 193, 228; Ville a. Joulie, *Bl.* [2] 7, 262; Popp, *A.* 156, 185; Müntz, *C. R.* 287, 679), and inuloid (Pöpp, *A.* 156, 190) also yield lævulose. Lævulose is formed by the oxidation of mannitol (Cotton, *Bl.* [2] 33, 546; Gorup-Besanez, *A.* 118, 273; Bodenbender, *Zeit. d. Ver.* 14, 812; Renard, *A. Ch.* [5] 17, 316), by the fermentation of mannitol by *B. aceti* and *B. celylinum* (A. J. Brown, *C. J.* 1896, 184; 1897, 641); from phenylglucosazone by reduction to isoglucosamine, and thence by the action of sodium nitrite; from glucosone by reduction with zinc and acetic acid (Fischer, *B.* 22, 87, 2566).

**Preparation.**—Inulin is heated with very weak sulphuric acid for some hours, after which the sulphuric acid is carefully precipitated by baryta water and the filtrate decolourised by charcoal and evaporated on the water-bath to a syrup. This is treated several times with absolute alcohol, which removes the water, and the syrup which remains put on one side for some time in a closed flask, when fine needles make their appearance, and in time the whole solidifies (Jungfleisch a. Lefranc, *C. R.* 93, 547; also Crookewitt, *A.* 45, 184; Krusemann, *A.* 282, 26; Wohl, *B.* 23, 2084). A 10 p.c. solution of cane sugar is carefully inverted with hydrochloric acid (20 c.c. to a litre of solution) at 60°. The solution is cooled to -5°, 6g. of slaked lime added for each 10 g. sugar, the temperature allowed to rise to 2°, and the lime lævulose carefully pressed from the rest of the solution and washed repeatedly with water. It is finally suspended in water, decomposed by oxalic acid, and the filtered solution evaporated *in vacuo* to a syrup which, when treated with absolute alcohol as above described, yields crystals of lævulose (Girard, *Bl.* [2] 33, 154; Dubrunfaut, *C. R.* 42, 901; 69, 438).

**Formula and synthesis.** See general part.

**Properties.**—Lævulose forms colourless, fine, shining needles, belonging to the rhombic system, the axial ratio is  $a:b:c = 0.80067:1.0.90674$ ; they are slightly biaxial as regards their action on polarised light; they have a composition corresponding to the formula  $C_6H_{12}O_6$ , melt at 95°, and lose water at 100°. According to Hönig a. Jesser (*M.* 9, 562), the crystals con-

tain water of crystallisation and have a formula  $20C_6H_{12}O_6 \cdot H_2O$ . If free from alcohol they are not deliquescent in the air (Hönig a. Schubert, *M.* 8, 529; Jungfleisch a. Lefranc, *l.c.*). The sugar is almost insoluble in cold absolute alcohol, and soluble in a boiling mixture of alcohol and ether (Dieck a. Tollens, *A.* 193, 228). With regard to the specific rotatory power of lævulose there are many and varied statements; all those based on the factors of unpurified solutions obtained by the inversion of inulin or cane sugar are worthless, as lævulose is extremely easily decomposed by acids (Jungfleisch a. Grimbert, *C. R.* 108, 144), and many apparent discrepancies may be explained by the fact that the optical activity varies very much with the temperature. Jungfleisch a. Grimbert (*C. R.* 107, 390) found for crystallised lævulose  $[\alpha]_D = -101.38^\circ - 0.56t + 0.108(p-10)$ , where  $t$  is the temperature and  $p$  the weight of lævulose in 100 c.c. solution. This formula holds for temperature 0°-40° and for concentrations below 40 p.c. The  $[\alpha]_D = -108^\circ$  ( $c = 10$  g. sugar in 100 c.c.), calculated from  $[\alpha]_D = -24.5$  for invert sugars, and  $[\alpha]_D = +68.5$  for dextrose agree very well with the numbers of Jungfleisch a. Grimbert. Hönig a. Jesser (*M.* 9, 562) give  $[\alpha]_D = -111.38$ ,  $c = 10$ ,  $t = 20^\circ$  for a carefully crystallised preparation. Herzfeld a. Winter (*B.* 19, 390) give for 20 p.c. solution at 20°  $[\alpha]_D = -71.4^\circ$ ; but these determinations cannot be for the pure body. Freshly-prepared solutions of crystallised lævulose have a greater sp. rot. power than after standing a short time; Pareus a. Tollens (*A.* 257, 160) found for a 10 p.c. solution at 20° observed in a 200 mm. tube,  $[\alpha]_D = -104.02^\circ$  six minutes after commencing solution, which sank to a constant value  $[\alpha]_D = -92.25^\circ$  in 35 minutes. This cannot have been pure lævulose.  $K = 100$ ; but Soxhlet makes it 92-93 (J. O'Sullivan, *C. J.* 1892, 408).

**Action of heat and acids.** Lævulose is exceedingly easily decomposed by heat and acids. Its aqueous solutions colour exceedingly quickly if heated for any length of time. Wohl (*B.* 23, 2084) found that by the action of minute quantities of acid on a hot concentrated solution of lævulose, a dextrin-like body was produced which was reconverted into lævulose by boiling with dilute acids. This instability accounts for the many different numbers which have been given for the sp. rot. power and for the fact that the opt. act. of invert sugar does not in all cases correspond with that of a mixture of pure lævulose and dextrose in equal quantities. On boiling with dilute sulphuric or hydrochloric acids, aceto-propionic, formic, and other acids are produced (Jungfleisch a. Grimbert, *C. R.* 108, 144; Grote a. Tollens, *A.* 175, 181; Sieben, *Zeitschr. d. Ver.* 34, 237; Conrad a. Guthzeit, *B.* 19, 2569).

**Action of alkalis.** Alkalis quickly decompose lævulose, especially on warming; caustic soda and baryta yield lactic acid among other products (Sorokin, *J. R.* 1885, 368). Sodium lævulose  $C_6H_7NaO_5$  is produced by acting on an alcoholic solution of lævulose with sodium ethylate (Hönig a. Rosenfeld, *B.* 12, 45). Lime yields a compound  $C_6H_{12}O_6 \cdot CaO \cdot H_2O$ , which is soluble in 137 parts cold water (E. Péligot, *C. R.* 90, 153; Herzfeld a. Winter, *B.* 19, 390); and  $2(C_6H_{12}O_6) \cdot 3CaO$ , which forms needles sol-

ble in 335 parts cold water (Dubrunfaut, *A. Ch.* [8] 21, 169). Similar compounds are formed with potash, baryta, lead oxide, and bismuth oxide (Herzfeld a. Winter, *B.* 9, 390, and v. Lippmann, *Zuckerarten*, p. 68). If a solution of levulose be boiled with lime, saccharin is formed (Scheibler, *B.* 13, 2212).

**Reduction.**—Levulose in alkaline solution is reduced by nascent hydrogen to mannitol, and more easily than dextrose (Scheibler, *B.* 16, 3010; H. Krusemann, *B.* 9, 1465; Herzfeld, *A.* 244, 274). Fischer (*B.* 23, 3684) finds that equal parts of mannitol and sorbitol are produced.

**Oxidation.**—Mercuric oxide and baryta boiled with an aqueous solution of levulose yield formic, glycollic and normal trioxobutyric acid (Börnstein a. Herzfeld, *B.* 18, 3353). Bromine water in the same way yields normal trioxobutyric acid (Hönig, *B.* 19, 171; Herzfeld a. Winter, *B.* 19, 390; *C. C.* 1886, 271). Levulose by oxidation always yields an acid containing less carbon atoms than itself (Herzfeld a. Börnstein, *C. C.* 1886, 187; Herzfeld a. Winter, *C. C.* 1886, 271; *B.* 19, 390). Chlorine and bromine with silver oxide oxidise levulose to glycollic acid (Häsiwetz a. Habermann, *A.* 155, 130; Kiliani, *A.* 205, 175). Nitric acid yields oxalic acid, tartaric acid, glycollic acid, formic acid, a little saccharic acid, malic acid, acetic acid, and racemic acid (Dragendorf, *Materialien zu einer Monographie des Inulins*; Kiliani, *A.* 205, 162; Hornemann, *J. pr.* 83, 283).

**Fermentation.**—Levulose ferments easily with yeast, with formation of alcohol and carbonic acid &c., but rather slower than dextrose, so that towards the end of a fermentation of invert sugar the solution is always levorotatory (Bourquelot, *A. Ch.* [6] 9, 245; *C. R.* 101, 958; *C. R.* 100, 1404 and 1466; Maumené, *C. R.* 100, 1505; 101, 695; Leplay, *C. R.* 101, 479; Gourgon a. Dubourg, *C. R.* 110, 865).

**Compounds with acids.** Chlorosulphonic acid gives a tetra-sulphate (Clässon, *J. pr.* [2] 20, 1 a. 18). Acetyl chloride yields an acetochlorhydrin (Colley a. Wachowitsch, *B.* 13, 2390; *Bl.* [2] 34, 326). With acetic anhydride, acetic acid, and zinc chloride levulose yields pentacetyl levulose (Erwig a. Koenigs, *B.* 23, 672). Benzoyl chloride yields pentabenzoyl levulose, m.p. 85° (Skraup, *M.* 10, 389).

**Compounds with bases.** See *Action of alkalis* above.

**Compounds with metallic salts.** Compounds with potassium or sodium chloride have not been described. A compound with lead chloride is known (Herzfeld a. Winter, *B.* 19, 390).

**Compounds with cyanogen.** By treatment with strong hydrocyanic acid, levulose yields a cyanhydrin  $C_6H_{11}O_5N$ , this crystallises from water in tabular monoclinic crystals, m.p. 110°–115°, and has a slight dextrorotatory power; fuming hydrochloric acid converts it into the lactone of fructoheptonic acid  $C_6H_{12}O_6$ , and this, heated with hydriodic acid and phosphorus, yields a heptolactone  $C_6H_{12}O_6$ , b.p. 220°, which does not solidify in a freezing mixture. When the lactone is further treated with hydriodic acid and phosphorus an acid is obtained boiling at 210°, which is identical with methyl-butyl-acetic acid as synthetically prepared (Kiliani, *B.* 18,

3066; 19, 221 and 1914; Kiliani a. Düll, *B.* 23, 449). Tetra-oxy-butane-tri-carboxylic acid  $COOH.(CH_2OH)_2.C(OH)(COOH)_2$  is obtained by oxidising fructoheptonic acid by nitric acid (Düll, *B.* 24, 348).

**Hydrazine compounds.** Levulose yields an osazone which appears to be identical with, and is prepared in the same manner as, dextrose osazone (*q.v.*).

**Anilides.** By heating an aqueous solution of levulose with aniline, an anilide is formed  $C_{12}H_{11}NO_5$ ; it is easily obtained in crystals which melt at 147° with partial decomposition (Sorkin, *B.* 19, 513; *J. R.* 1886, 129; 1887, 877). With hydroxylamine levulose combines to form levulosoxim (Wohl, *B.* 24, 993). It strongly resembles dextrosxim in appearance, m.p. 118°, it is levorotatory, and reduces ammoniacal silver solutions on warming, whilst dextrosxim does so in the cold.

**Galactose.** Lactose.  $C_6H_{12}O_6$ . Galactose does not occur in nature.

**Formation.**—By the action of dilute acids on many carbohydrates and similar substances of vegetable and animal origin. Lactose yields dextrose and galactose (Pasteur, *C. R.* 42, 347; Fudakowski, *B.* 9, 42; *C. C.* 1877, 6). Raffinose yields levulose, galactose, and dextrose.  $\alpha$ -Galactin,  $\beta$ -galactin, paragalactin, lactosin, agar-agar, cartagheen moss, plum gum, peach gum, gum arabic, gedda gum, and many other similar vegetable substances, yield galactose amongst other products of their hydrolysis (Mintz, *Bl.* [2] 37, 409; *A. Ch.* [6] 10, 566; *C. R.* 94, 453; 102, 624, 631; A. Meyer, *B.* 17, 690; Bauer, *J. pr.* [2] 30, 375; *L. V.* 1888, 33 a. 214; Hädicke, Bauer a. Tollens, *A.* 238, 302; Kiliani, *B.* 13, 2304; 15, 36; v. Lippmann, *B.* 17, 2238; Scheibler, *B.* 1, 58; 6, 612; 17, 1729; O'Sullivan, *C. J.* 1884, 41; 1391, 1029; Hädicke a. Tollens, *A.* 238, 308; Schulze a. Steiger, *B.* 19, 827; 20, 290; *L. V.* 36, 391; Schulze, *B.* 25, 2213; Maxwell, *Am. C.* 12, 51 a. 265; v. Lippmann, *Deutsche Zuckerrind.*, 1887, 455; *B.* 20, 1001; Stone, *Am.* 12, 435). Galactose is also produced by the long-continued action of dilute sulphuric acid on certain nitrogenised constituents of the brain (Thudichum, *Ann. of Chem. Med.* [2] 209; Thierfelder, *Z. P. C.* 14, 209; Brown a. Morris, *C. J.* 1890, 57). This sugar was called by the discoverer *cerebrose*; B. a. M. proved it to be galactose.

**Preparation.**—A solution of lactose (milk-sugar) containing in every 100 c.c. 25 g. dry lactose; 2 to 3 grams  $H_2SO_4$  is digested in a flask on the water-bath for 2½ to 3 hours, the water being kept boiling all the time and care being taken by continual shaking of the flask to avoid colouring. The acid is, on cooling the solution, carefully neutralised with baryta water and the  $BaSO_4$  separated by filtration. On evaporating the filtrate to a strong syrup in a vacuum solidification takes place in a short time. The solid crystallised mass is digested several times with dry methyl alcohol; this dissolves out the dextrose and other products of the action of the acid on lactose and the hydrolysed sugars, and leaves galactose as a white crystalline powder. This is dissolved in the least possible quantity of boiling water, again allowed to solidify, and again treated with boiling methyl alcohol. If

the whole of the lactose hydrolysed, and it generally is under the conditions indicated, the residue is white, nearly pure, galactose. It can be rendered pure by recrystallisation from water. If the crystals are allowed to form slowly from solutions not too concentrated they are distinct and well-defined (Rendell, *N. Z.* 4, 163; Soxhlet, *J. pr.* 2, 21, 269). The sugar can also be prepared from certain gums of the arabin group. For this purpose the most suitable are those having a levorotatory power and yielding the larger percentage of mucic acid on oxidation with nitric acid. The dextro-gums also yield the sugar, but in less quantity (O'Sullivan, *C. J.* 1884, 41; 1891, 1029). A solution of the gum selected—gum arabic, Turkey, Levantine or East India gum—is made containing about equal weights of water and gum; this is heated in a flask in a water-bath as high as the boiling bath will take it, and 5 grams  $\text{H}_2\text{SO}_4$  diluted to 15 c.c. added for every 100 c.c. of the gum solution employed. The mixture is digested for 30 to 35 minutes, then rapidly cooled, and alcohol, S. G. 0.83, added as long as a pp. is produced. This pp. is again dissolved in water, and again ppd. One or two repetitions of this process frees the pp. from arabinose. A solution of the same strength as that above described for the original gum is then made of the pp. and heated as high as the boiling water of a water-bath will take it, and then for every 100 c.c. of the solution 5 grams  $\text{H}_2\text{SO}_4$  diluted to 15 c.c. added. At the end of about 8 hours' digestion the solution is cooled, carefully neutralised with baryta water, and alcohol, 0.82, added as long as a pp. is thrown out. The alcoholic solution becomes clear on standing; it contains galactose, and on concentration in a vacuum yields crystals of the body in a fairly pure state. They may be completely purified by washing with methyl alcohol, recrystallising the residue from ethyl alcohol, and finally from water.

*Formula and synthesis.* See general part.

*Properties.*—Galactose crystallises in hexagonal plates, m.p.  $163^\circ\text{--}164^\circ$  (after drying at  $100^\circ$ ) (E. Bourquelot, *J. Ph.* [5] 13, 51), or, according to v. Lippmann (*B.* 18, 3335), in microscopic six-cornered prisms and needles, m.p.  $168^\circ$ . Galactose is easily soluble in water, almost insoluble in methyl alcohol. Solutions of galactose rotate a ray of polarised light to the right, the specific rotatory power for the D line being given by the formula  $[\alpha]_D = 83.883 + 0.0785P - 0.209t$  (Meissl, *J. pr.* [2] 22, 97); this formula agrees well with numbers found by other observers. Freshly-prepared solutions exhibit the phenomenon of bi-rotation (Pasteur, *J. pr.* 68, 428). Parous a. Tollens (*A.* 257, 160) observed an angle of  $[\alpha]_D = 117.48^\circ$  in a 10 p.c. solution at  $20^\circ$ , 7 minutes after commencing solution.  $K = 100$ , and varies slightly with the conditions of determination.

*Action of acids.* By prolonged heating with dilute acids, galactose yields aceto-propionic and formic acids (Kent a. Tollens, *A.* 227, 228; *B.* 17, 668; Conrad a. Guthzeit, *B.* 18, 2905); sulphuric acid and chloro-sulphuric acid yield galactose-sulphuric acids (Hönig a. Schubert, *M.* 7, 455; Claesson, *J. pr.* [2] 20 a. 18).

*Action of alkalis.* Alkalis colour galactose yellow; the action of milk of lime produces saccharin (Cuisinier, v. Lippmann, *Zuckerarten*).

Fusion with KHO gives rise to acetic and oxalic acids.

*Reduction.*—By reduction with sodium-amalgam, galactose yields dulcitol and other alcohols (Bouchardat, *A. Ch.* [4] 27, 79).

*Oxidation.*—Bromine oxidises galactose to galactonic acid (lactonic acid)  $\text{C}_6\text{H}_{10}\text{O}_7$ , isomeric with gluconic acid (Hlasiwetz a. Habermann, *A.* 122, 96; Kiliani, *B.* 18, 2307; 18, 1551; Bauer, *J. pr.* [2] 30, 379); which when heated loses 1 mol. water, and is converted into the lactone; it yields with phenylhydrazine a hydrazone which melts at  $200^\circ\text{--}205^\circ$  with decomposition (Fischer a. Passmore, *B.* 22, 2731). Nitric acid oxidises galactose to mucic acid, isomeric with saccharic acid. As mucic acid is only slightly soluble in water, the yield of mucic acid, which is normally 75 to 78 p.c., is sometimes made use of for the estimation of galactose; but the yield varies considerably with the condition of experiment (Pasteur, *C. R.* 42, 349; Kent a. Tollens, *A. Ch.* 227, 228). Neutral or alkaline solutions of cupric hydroxide are reduced by galactose; carbonic, formic, glycollic, and lactic acids are produced (Habermann a. Hönig, *M.* 5, 208).

*Fermentation.*—According to Kiliani (*B.* 18, 2305) and Koch (*B.* 20, Ref. 145), galactose does not ferment with yeast, whilst v. Lippmann (*B.* 17, 2238; 20, 1001), Bourquelot (*C. R.* 106, 283), and Pasteur find that it does ferment. Stone a. Tollens (*A.* 249, 257; *B.* 21, 1572) find that it ferments with beer yeast as well as with *Mucor racemosus*, but slower than dextrose. Certain bacteria yield lactic acid (Pranzmovaski a. v. Tieghem, *B.* 12, 2087).

*Compounds.*—Galactose yields a crystalline compound with sodium chloride (Fudakowsky, *Bl.* [2] 30, 433). With a solution of baryta in methyl alcohol, galactose yields the compound  $(\text{C}_6\text{H}_{10}\text{O}_6)_2\text{Ba}_2\cdot\text{BaO}$  (Fudakowsky, *l.c.*). With acetic anhydride, a pentacetate is produced  $\text{C}_6\text{H}_9\text{O}(\text{C}_2\text{H}_5\text{O})_5$ , m.p.  $62^\circ\text{--}66^\circ$  (Fudakowsky). According to Erwig a. Koenigs (*B.* 22, 2207) this body melts at  $142^\circ$ , crystallises in rhombic prisms, reduces Fehling's solution, is dextro-rotatory, and differs in all its properties from Fudakowsky's galactose pentacetate. With aniline, galactose forms an anilide, crystallising in long triclinic prisms, and levorotatory (Sorokin, *J. R.* 1887, 377; *B.* 19, 293). With hydroxylamine, galactose yields the oxim  $\text{C}_6\text{H}_{11}\text{NO}$ , the crystals melt at  $175^\circ\text{--}176^\circ$ , and are easily soluble in water and weak alcohol (Rischbieth, *B.* 20, 2673). With ortho-diamido-benzene, galactose yields galactose-o-diamido-benzene  $\text{C}_6\text{H}_4(\text{NH})_2\cdot\text{C}_6\text{H}_9\text{O}_6$ , melting at  $246^\circ$  with decomposition. Galactose- $\gamma$ -diamido-benzoic acid  $\text{COOH}\cdot\text{C}_6\text{H}_4(\text{NH})_2\cdot\text{C}_6\text{H}_9\text{O}_6 + \text{H}_2\text{O}$  crystallises in needles (Griess a. Harrow, *B.* 20, 3111). With hydrocyanic acid, galactose yields galactohexonamide  $\text{C}_6\text{H}_{11}\text{NO}$ , m.p.  $194^\circ$ ; it is converted into the barium salt of galactohexonate acid  $\text{C}_6\text{H}_9\text{O}_6$ , by digesting with baryta. The free acid melts at  $145^\circ$  and crystallises in slender needles; it is reduced by hydriodic acid and phosphorus to the lactone of normal  $\gamma$ -oxyheptonic acid (b.p.  $231^\circ$ ) and a very small quantity of normal heptonic acid (Maquenne, *C. R.* 106, 286; Kiliani, *B.* 21, 915; 22, 521 a. 1886). With phenylhydrazine, galactose forms galactose-phenylhydrazone, crystallising in colourless

needles, m.p. 158°, and galactose-osazone, m.p. 193°–194° (Fischer, *B.* 20, 821). Fischer's first determination of the melting-point (*B.* 17, 579) was 182°, Scheibler (*B.* 17, 1731) gave 171°, and other observers have given lower numbers; this may be accounted for by the fact that unless the osazone be heated up very quickly it decomposes before it fuses. By the action of hydrochloric acid it yields galactose-osone (Fischer, *B.* 22, 87). Galactose also yields a diphenylhydrazide, m.p. 157° (Stahel, *A.* 258, 212). Galactose forms a penta-benzoate  $C_6H_5O(C_6H_5O)_5$ , m.p. 165° (Skraup, *M.* 10, 389).

**Sorbose.** Sorbinose  $C_6H_{12}O_6$ . Sorbose is obtained from the juice of the mountain ash after allowing it to stand for some time. It is doubtful if it exists in the fresh juice as a free sugar, but it is probably formed by the decomposition of a glucoside (Pelouze, *A. Ch.* [3] 35, 222; Bousingault, *O. R.* 74, 939; Delfs, *B.* 4, 799; Byschl, *J. pr.* 62, 504; Freund, *M.* 11, 560). The expressed juice of the unripe berries of the mountain ash is allowed to ferment for eight or ten months, the clear solution is filtered from the organisms by which the fermentation was effected, and evaporated to a syrup, when the sorbose crystallises out on standing. It forms colourless rhombic crystals easily soluble in water. Its solutions are levorotatory: for 10 p.c. solution,  $[\alpha]_D = -43.4^\circ$  (Wehmer a. Tollens, *B.* 19, 708). It is oxidised by chlorine and silver oxide to glycollic acid; it behaves with bromine water like levulose, being practically unaltered (Kiliani a. Scheibler, *B.* 21, 3276); nitric acid oxidises it to oxalic, ascorbic and tartaric acids. By more careful oxidation with  $HNO_3$ , Kiliani a. Scheibler (*l.c.*) obtained trioxylglutaric acid. Copper hydrate oxidises it to carbonic and formic acids and other bodies, amongst which is possibly glyceric acid (Desaignes, *J. pr.* 89, 313; Hlasiwetz a. Habermann, *A.* 155, 129; Habermann a. Hönig, *M.* 5, 208). Hydriodic acid reduces it to hexyl iodide (Kiliani a. Scheibler, *l.c.*). It reduces Fehling's solution, and is coloured yellow by alkalis. Sorbose ferments slowly with beer yeast (Stone a. Tollens, *A.* 249, 257). By prolonged heating with dilute acids it is decomposed, yielding, amongst other bodies, levulinic acid (Wehmer a. Tollens, *l.c.*). With phenyl-hydrazine it yields an osazone  $C_{18}H_{22}N_4O_8$ , m.p. 164°, which is almost insol. in water, but fairly easily soluble in alcohol, from which it crystallises in fine microscopic needles (Fischer a. Tafel, *B.* 19, 1920; 20, 217 and 2566; Fischer, *B.* 20, 828).

**Mannose.** *Seminose*  $C_6H_{12}O_6$ . This sugar does not occur free in nature.

**Formation.**—It is obtained by the action of dilute sulphuric acid on the so-called reserve cellulose (Reiss, *B.* 22, 609, 3218) and on salep juice (Tollens a. Gans, *A.* 249, 256), and by the oxidation of mannitol (Fischer a. Hirschberger, *B.* 21, 1805; 22, 1155 a. 3218; Calet, *J.* 1860, 250; Gorup-Besanez, *A.* 118, 257; Dufert, *B.* 17, 227).

**Preparation.**—Sifted ivory nut shavings (1 pt.) are digested with 6 p.c. hydrochloric acid (2 pts.) for six hours on the water-bath, filtered hot, and the residue pressed and extracted with water. The brown solution contains the sugar. It may be obtained as hydrazide by adding

phenyl-hydrazine acetate, and this is decomposed by hydrochloric acid with reproduction of the sugar (Fischer a. Hirschberger, *B.* 22, 865 a. 3218).

**Properties.**—Mannose is precipitated from its alcoholic solution by ether; the syrup, on keeping under absolute alcohol, solidifies to a hard colourless mass which shows no sign of crystalline structure. Its solutions are dextrorotatory,  $[\alpha]_D = 13.0^\circ$  approx.; they are reduced by Fehling's solution, 1 c.c. of this solution being reduced by 4.307 mgm. mannose, i.e.  $K = 110^\circ$ – $112^\circ$ . It is fermented by yeast.

**Reduction.**—Mannose is reduced by sodium-amalgam to mannitol.

**Oxidation.**—Mannose is oxidised by bromine to mannonic acid, the lactone of which ( $C_6H_8O_6$ ) crystallises in colourless needles, readily soluble in water and less in alcohol; it is dextrorotatory in aqueous solutions,  $[\alpha]_D = 53.8^\circ$ , and forms a phenylhydrazide  $C_{12}H_{14}N_2O_6$ , m.p. 214°–216°. Its optical isomeride, *l*-mannonic acid, is obtained by the nitrile reaction from arabinose. Oxidised with nitric acid, manno-saccharic acid is obtained (Easterfield, *C. J.* 1891, 306; Fischer, *B.* 24, 539). It crystallises in colourless needles, m.p. 180°–190°, and  $[\alpha]_D = 201.8^\circ$ . With ammonia it yields a monamide, and with phenylhydrazine a mono- and di-phenylhydrazide. Kiliani's meta-saccharic acid is its optical isomeride (*l*-manno-saccharic acid) (Fischer, *l.c.*).

**Action of acids.** Hot hydrochloric acid has little action on mannose, but if the heating be continued for some time, humus substances are formed.

**Action of alkalis.** Alcoholic potash precipitates a flocculent hygroscopic substance from solutions of the sugar.

**Compounds.**—Lead acetate and ammonia produce a precipitate which becomes yellow on keeping. With phenylhydrazine it yields a sparingly soluble hydrazide,  $C_{12}H_{14}N_2O_6$ , crystallising in yellow slender prisms, m.p. 195°–200°, levorotatory in dilute hydrochloric acid solution. By heating the hydrazide with excess of phenylhydrazine hydrochloride, sodium acetate, and water, it yields an osazone  $C_{18}H_{22}N_4O_8$ , crystallising in yellow needles, which is identical with phenylglucosazone. With di-phenyl-hydrazine it yields a di-phenyl hydrazide, m.p. 155°. With hydrocyanic acid it yields a compound which is easily decomposed, yielding mannose-heptonic acid; its lactone  $C_8H_{10}O_6$  crystallises in needles, m.p. 148°–150°; by reduction with hydriodic acid normal heptonic acid is obtained. With hydroxylamine mannose yields an oxim  $C_6H_{13}O_5N$ , m.p. 134° (Reiss, *l.c.*; Fischer a. Hirschberger, *B.* 22, 1155). Aceto-chloro-mannose is obtained by the action of acetyl chloride (Fischer, *l.c.*).

**Phlorose**  $C_6H_{12}O_6$ . This has been shown to be identical with dextrose (Rennie, *C. J.* 887, 636; Fischer, *B.* 21, 988).

**Crocose**  $C_6H_{12}O_6$ . Kayser (*B.* 17, 2232) a. Rochleder a. Mayer (*J. pr.* 74, 1) obtained a dextrorotatory sugar by heating saffron (from *Crocus electus* or yellow shoots of *Gardenia grandiflora*) with dilute sulphuric acid. It forms rhombic crystals, which only reduce half as much copper oxide as dextrose. According to Fischer (*B.* 21, 983), it yields, with phenylhydrazine, an osazone identical with phenylglucosazone.

**Lokaose**  $C_6H_{12}O_6$  is obtained from lokao or Chinese green by boiling with dilute sulphuric acid, lokaonic acid yielding lokaonic acid and lokaose  $C_{12}H_{24}O_{17} = C_{12}H_{24}O_{18} + C_6H_{12}O_6$ . Lokaose forms minute acicular crystals, and is distinguished from dextrose by being optically inactive and having a lower reducing power ( $K = 50$ ) (R. Kayser, *B. 18*, 3417).

**Tabakose** is said to exist in tobacco (Attfield, *Ph. 541*).

**Digitalose**  $C_6H_{12}O_6$  is obtained, together with dextrin, by the action of strong hydrochloric acid on digitalin; oxidised with bromine it yields digitalonic lactone  $C_6H_{12}O_6$ ; hence the formula of the sugar (Kiliani, *Ar. Ph. 230*, 250; *B. 25*, 2116).

**Aromatic sugar.** *Phenyltetrose* (Fischer a. Stewart, *B. 25*, 2555). Cinnamaldehyde cyanhydrin, when dissolved in chloroform and bromine added, yields phenyl-dibromo-oxybutyronitril  $CHPhBr.CHBr.CH(OH)CN$ ; this when heated with hydrochloric acid yields phenylbromodioxybutyrolactone

$CHPh \begin{smallmatrix} \text{CH.Br} \\ \diagup \quad \diagdown \\ \text{O.CO.} \end{smallmatrix} CH.OH$ , from which the acid  $CHPh.CHBr.CH(OH).COOH$  is easily obtained; on reduction this yields phenyltetrose  $OH.CHPh.CH(OH).CH(OH).COH$ . It yields a phenylhydrazide, m.p. 154°.

For *Acrose*, *Formose*, *Glycerose*, see *Synthesis of the Sugars*.

#### CLASS II. The 'on' sugars.

##### (a) *Dipentose*.

**Arabinon**, **diarabinose**, or **arabiniose**  $C_{10}H_{18}O_9$ . A product of the partial hydrolysis of a series of gum acids. A 25 p.c. solution of any of the strongly rotating gum acids is heated to boiling, and 2 g. sulphuric acid for every 100 c.c. solution, previously diluted with 4 to 5 volumes water, added. At the end of 10 to 15 minutes' digestion the solution is quickly cooled and alcohol, sp.gr. '830, added as long as a precipitate forms. The clear alcoholic solution contains *arabinon* and *arabinose*, and some *arabinon* is taken down with the precipitate; and on again dissolving it in a little water and reprecipitating with alcohol, the *arabinon* often appears on the surface of the syrup in spherocrystals, and the alcoholic supernatant liquid contains it in quantity. It is easily soluble in water and methyl alcohol. Dilute ethyl alcohol also dissolves it, but absolute alcohol precipitates it as a syrup from a strong methyl alcohol solution. Ether also precipitates it. Its solutions are dextrorotatory,  $[\alpha]_D = +202^\circ$  (a. 6'466), there appears to be an increase with the concentration; it reduces Fehling's solution;  $K = 58$  ( $K = 57.5$  if 2 mols. sugar reduce 9 mols.  $CuO$ ).  $D = 3.95$ . It tastes sweet, and is easily diffusible. Dilute acids hydrolyse it, the sole product being *arabinose*,

(O'Sullivan, *C. J. 1890*, 59).

##### (b) *Dihexoses*.

**Cane sugar.** *Saccharon*, *sucrose*  $C_{12}H_{22}O_{11}$ .

**Occurrence.**—Cane sugar is widely distributed throughout the vegetable kingdom, and is frequently accompanied by dextrose and levulose. The most important sources are the sugar-cane (*Saccharum officinarum*); the sugar-beet (*Beta*

*vulgaris*); the sugar-maple (*Acer saccharinum*) and *Sorghum saccharatum* (Girard, *C. R. 102*, 108; *Centrbl. f. Agric. Ch. 1886*, 683; Berthelot, *C. R. 53*, 583; *A. Ch. [3] 55*, 289; Buignet, *A. Ch. [3] 61*, 233; Maxwell, *L. V. 86*, 15, *Am. 12*, 265; *Reports of the Department of Agriculture, Washington*, No. 6; *The Sugar Industry of the United States*, by Wiley, 1885; *The Literature of the Sugars*, H. L. Roth, London, 1890; Gössmann, *A. 104*, 335; Hermbstädt, *Gehlen's J. f. Ch. Ph. Min.*, 8, 589 (1809); Boier, *Jahresb. f. Zuckerfabr. 5*, 139; Balland, *J. Ph. [4] 25*, 97; Corenwinder, *C. R. 83*, 1238; A. v. Wachtel, *B. C. 1880*, 344; Stone, *B. 23*, 1406; Wiley, *C. N. 51*, 88; *Ann. Agronom. 11*, 392; Schulze a. Seliwanoff, *L. V. 1887*, 403; Washburn a. Tollens, *B. 22*, 1047; Stingl a. Morawski, *M. 7*, 176; 8, 82; Déon, *Bl. [2] 82*, 125; Reali, *G. 17*, 325; Schulze, *L. V. 1887*, 403, 408; v. also the references under the heading *Dextrose*, *Occurrence*, and many others throughout the range of chemical literature).

**Formation.**—Icery (*A. Ch. [4] 5*, 350) and Jackson (*C. R. 46*, 55) found that in the early period of vegetation of many plants, invert sugar only occurs, and that cane sugar is formed later. Leplay (*C. R. 46*, 444) confirms this observation in the case of sugar-cane. Barley contains from 0.8 to 1.6 p.c. cane sugar, whereas germinated barley (malt) contains from 2.8 to 6.0 p.c. cane sugar; the starch of the endosperm being converted into cane sugar for the use of the growing plant (Kuhnemann, *B. 8*, 202, 387; Kjeldahl, *Res. du C. R. des Travaux du Lab. de Carlsberg*, 1881, 189; O'Sullivan, *C. J. 1896*, 58). Brown a. Morris (*C. J. 1890*, 516) found that the cane sugar of germinated barley was chiefly localised in the embryo, whilst maltose appears in the endosperm; they consider that starch is first converted by diastase into maltose in the endosperm, and then, being transferred to the embryo, is converted into cane sugar for the purpose of growth. Colley a. Vakovitch (*Bl. [2] 34*, 326) may have obtained cane sugar by acting on barium inulosate with acetochlorhydroses, but the evidence is not satisfactory. Aubert a. Girard (*D. P. J. 257*, 298) state that by passing an electric current through acidified starch-paste at 100°C. cane sugar may be manufactured (?).

**Preparation.**—(For the commercial preparation of cane sugar see Thorpe's *Dictionary of Applied Chemistry*.) The best samples of commercial cane sugar consist of almost the pure sugar. Dry, clean, glassy sugar-candy is sufficiently pure for most purposes. Absolutely pure saccharon may be obtained by careful crystallisation from warm aqueous solutions; or a cold, clear saturated solution made with carefully-purified distilled water is mixed with an equal volume of purified ethyl alcohol, S.G. '820, with continual stirring. On standing, saccharon crystallises out in pure glassy crystals.

**Properties.**—Cane sugar forms fine large monoclinic hemihedral crystals, S.G.  $\frac{1.75}{1.75}$  1.58047 (Schröder, *B. 12*, 562; Gerlach, *D. P. J. 172*, 81 and 286; Joule a. Playfair, *C. J. 1*, 130), which do not contain water of crystallisation. It is easily soluble in water; 100 parts of a solution saturated at 0° contain 65.0 pts. saccharon, at 20° 67 pts., and at 40° 75.8 pts. (Scheibler,

**Z. V. 22, 253).** A large number of figures have been given to represent the relation between the quantity of sugar in solution and the specific gravity thereof (v. Lippmann's *Zuckerarten*; Brown a. Heron, *C. J.* 1879, 644; Périer, *C. R.* 108, 1202), and much apparent contradiction exists on the subject; but the bulk of this disappears when the processes by which the figures were obtained are inquired into. The general agreement is with the numbers of Balling, confirmed, within the limits of error, by Scheibler a. Mateczek (*Z. V.* 15, 586; 24, 827; 27, 32) and others. These are:—

Per cent. saccharon in sol.	Sp. gr. sol. $\frac{175^{\circ}}{175^{\circ}}$
5	1.01970
10	1.04014
20	1.08329
40	1.17943

The relation is sometimes more convenient when expressed as weights in measure. If a vessel be made to hold 100 g.  $H_2O$  at  $15.5^{\circ}$ , and such is the 100 c.c. vessel most generally in use, then a solution containing

20 g. saccharon in this 100 c.c. = sp. gr.	1.07686
10 " " " " "	1.03857
5 " " " " "	1.01931
1 " " " " "	1.00386

Hence, if the sp.-gr. of a pure cane sugar is known the amount of sugar in the 100 c.c. can be arrived at broadly by dividing the S.G. — 1.000 by .00385. This number multiplied by 1000 has been called the D of the sugar.  $D = 3.85$  for saccharon. The use of the number gives too low an indication for the higher specific gravities and too high a one for the lower ones, being almost accurate for solutions containing between 10 and 20 g. sugar per 100 c.c. It is a useful, practical factor when its meaning and value are understood, being at most 3 per 1000 incorrect.

Concentrated sugar solutions possess a higher boiling-point than water, an 80 p.c. solution boils at  $112^{\circ}$ , a 90.8 p.c. solution at  $130^{\circ}$  (Gerlach, *D. P. J.* 172, 31 and 286).

Solutions of pure cane sugar crystallise quickly, but if foreign matters are present the crystallisation is very much slower, and the forms of the crystals vary with the character of the impurity; some impurities entirely prevent crystallisation. These facts play a most important part in the refinery (see art. in DICTIONARY OF APPLIED CHEMISTRY and v. Lippmann's *Zuckerarten*, p. 115). Solutions of cane sugar are highly diastinctic (Hartley, *C. J.* 1887, 59). Cane sugar is soluble in methyl and ethyl alcohol, acetone, and glycerin in proportion to the amount of water they contain, being almost insoluble in them when they are anhydrous (Scheibler, *Z. V.* 22, 246; *B.* 5, 343). Solutions of cane sugar and the fused sugar are optically active, rotating the plane of polarisation to the right; crystallised sugar is not optically active. The oldest value given for specific rotatory power is  $[\alpha]_D = +73.8^{\circ} = [\alpha]_D = +66.6^{\circ}$  (24.21-67:78.8°:66.6°).

This is only an approximate average number, much of the same value as the D described

above. It is the *apparent* specific rotatory power, and may be called the working value. Tollens (*B.* 17, 1757), Schmitz (*B.* 10, 1419), Girard a. de Luyes (*C. R.* 80, 1355), and Calderon (*C. R.* 83, 393), from numerous observations worked out an absolute value. Tollens gives  $[\alpha]_D = 66.386 + 0.015035P - 0.0003986P^2$ , where P is the p.c. of sugar; Schmitz's numbers are  $[\alpha]_D = 64.156 + 0.051596q - 0.00028052q^2$ , where  $q$  = p.c. of water. The optical activity diminishes with the concentration of the solution, so that for a 100 p.c. solution (i.e. for the dry sugar, if the curve follows the same course as the observations) the specific rotatory power is  $[\alpha]_D = 64^{\circ}$  approximately, while very weak solutions, as 1 p.c. for example, it is  $[\alpha]_D = 67^{\circ}$  (Pibram, *B.* 20, 1849; Nasini a. Villavecchia, *Gaz.* 22, 1, 97). The temperature of observation has but a very slight influence on the optical activity (Dubrunfaut, *A. Ch.* [3] 18, 99; Andrews, *M. S.* [4] 3, 1366). The specific rotatory powers of solutions of the sugar in mixtures of water and ethyl alcohol, methyl alcohol, and acetone respectively are slightly greater than that of aqueous solutions; if the latter be taken at  $[\alpha]_D = 66.6^{\circ}$  they are respectively  $[\alpha]_D = 66.83^{\circ}$ ,  $68.63^{\circ}$ , and  $67.40^{\circ}$  (Tollens, *B. C.* 1881, 570). The optical activity of fused sugar is less than that of its solutions, and diminishes according to the length of time it has been kept fused. This is, no doubt, due to the presence of decomposition products. The specific rotatory power of aqueous solutions is altered by the presence of most foreign substances; alkalis and alkaline earths diminish it (Thomsen, *B.* 14, 1649; v. Lippmann, *Zuckerarten*, p. 157; Farnsteiner, *B.* 23, 3570). Lead acetate does not appear to have any influence, while ammonia increases the rotation (Ost, *N. Zeitsch. f. Rubens-Ind.* 9, 42). The dispersion of cane-sugar solutions is almost the same as that of quartz, so that the rotation of the plane of polarisation caused by a sugar solution may be almost completely neutralised by a plate of left-handed quartz of the correct thickness. Grimbert (*J. Ph.* [5] 16, 295) gives  $[\alpha]_D = 66.45^{\circ}$  and  $[\alpha]_C = 52.85^{\circ}$ , so that the dispersive power for these two wave-lengths is 1.257. The refractive index for sugar solutions has been determined for seven lines of the spectrum (Obermeyer, Landolt-Börnstein, *Physikalisch-chem. Tabellen*, Berlin, 1883, p. 213; Kanonnikoff, *B.* 16, 3047). Gladstone (*C. J.* 1891, 589) finds the molecular refraction of cane-sugar solutions to be 118.7 for the A line, and the molecular dispersion between A and H lines 4.73.

**Action of heat.** Dry cane sugar melts at  $160^{\circ}$ , and solidifies on cooling, if care be taken and the temperature does not exceed  $160^{\circ}$ , to a colourless, glassy mass; but if the temperature be maintained the fused mass becomes slightly coloured, and on cooling yields the substance known as barley-sugar, this after a time becomes crystalline; but even with the greatest care it seems impossible to fuse the sugar without producing some decomposition. With the appearance of the colour dextrose and levulose are probably the chief products; but although much work has been done on the subject, the exact nature of the alteration is not settled. A little furfural is formed at times (Gélie, *A. Ch.* [3] 57, 234; *C. R.* 61, 331; Schiff, *B.* 20, 540). When the tempe-

<sup>1</sup> *Z. V.* = *Zeitschrift des Vereins für die Rübensuckerindustrie des deutschen Reiches.*

rature is raised to 200° distinct decomposition sets in, caramel is formed, gases are evolved, and finally a residue of charcoal remains. Among the gases are carbon dioxide, carbon monoxide, marsh gas, ethylene, acetylene; among the volatile products are water, acetone, formic, acetic, and propionic acids, aldehyde, furfural, acrolein, benzoic aldehyde, and a bitter substance assamur (Völckel, *A. Ch.* 59; 86, 63; 87, 303; Fremy, *A.* 15, 278; Schiff, *B.* 20, 540; *A.* 238, 380; Reichenbach, *A.* 49, 3). Caramel has the same composition as cane sugar, less one or more molecules of water. It is soluble in water and partly soluble in alcohol, and probably consists of a mixture of several bodies. Baryta and basic lead acetate give precipitates with it. It combines with aniline, reduces some metallic salts, and yields an acid with chlorine. It is largely used as a colouring matter in cookery, brewing, &c. (Gélis, *A. Ch.* [3] 52, 386; 65, 190 a. 496; Graham, *A. Ch.* 65, 190; Péligot, *A. Ch.* [2] 67, 172; Völckel, *A.* 75, 59; 85, 74; Pohl, *J. pr.* 82, 148; Schiff, *B.* 4, 908; Wachtel, *Org. d. Centr.-Ver.* 17, 930).

It seems proved that when dry saccharon is heated at 100°, even for a long time, no change takes place, and, as has been said, the sugar can be heated to the melting-point, 160°, without producing any marked decomposition, but it would appear that rapid heating to this temperature can produce a mixture of dextrose and levulose, without any change in weight. If, however, a mixture of 100 pts. of the sugar and about 5 pts. water is heated at 150° for some time, a mixture is produced which contains little or no unaltered saccharon, but which consists, in part at least, of a sugar said to be optically inactive, and to be a compound of bi-rotating dextrose and levulose. Other bodies must also be present, probably dextrose and levulose. The compound sugar is, no doubt, present, but inasmuch as it has never been isolated it cannot be said with certainty that it is inactive (Morin, *C. R.* 86, 1033; Berzelius a. Mitscherlich, *J. Ph.* 3, 4, 216). The so-called inactive sugar is easily converted by boiling with water into dextrose and levulose. Neutral aqueous solutions of saccharon are slowly inverted on boiling. They are, however, stable in the cold, if sterilised, and can be concentrated under diminished pressure at 50°-60° without undergoing much change (Kreuser, *Z. V.* 25, 521; Béchamp, *A. Ch.* [3] 54, 28; Morin, *C. R.* 86, 1,083; Horsin-Déon, *Bl.* [2] 82, 121; Gunning, *Z. V.* 27, 895). By heating to 150°-200° in a sealed tube, humus substances, formic acid, pyrocatechin, and other bodies are formed (Löw, *Z.* 1867, 510; Hoppe-Seyler, *B.* 4, 15).

**Action of acids.** All dilute acids, even carbonic acid, hydrolyse (invert) cane sugar, causing the assimilation of one molecule of water and the production of equal quantities of dextrose and levulose,

This mixture is called invert sugar. The experiments made on this phenomenon may be classified under two headings: (a) the action of different acids acting under the same conditions on the sugar solutions; (b) the action of the same acids under varying conditions. With

regard to those coming under the first heading, Ostwald's experiments are the most complete (*J. pr.* [2] 29 385; 30, 93 a. 225; 81, 807; Koral, *J. pr.* [2] 84, 109). He examined the action of thirty-two acids, and finds that there is a close relation between the constants of inversion and the affinities of the acids. See also Fleury (*D. P. J.* 219, 436; *J. Ph.* [4] 22, 423). With regard to reactions coming under the second heading, it is found that inversion proceeds more rapidly in hot solutions than in cold ones (several formulae have been given to express this relation, *v. Arrhenius, Zeit. phys. Ch.* 4, 226; Urech, *B.* 20, 1836); that increase in the percentage of acid increases the rapidity of inversion; that, the percentage of acid to water being constant, increase of volume decreases the time; and that the percentage of acid to sugar being constant, increase of volume (dilution) increases the time (Löwenthal a. Lenssen, *J. pr.* 85, 321 a. 401; Urech, *B.* 13, 1696; 15, 2130; *B. C.* 1881, 670; 1883, 501). The presence of neutral salts sometimes increases and sometimes diminishes the rapidity of inversion; for a detailed account see Spohr (*J. pr.* [2] 32, 32 and 33, 265). If the heating be long continued, or if too strong acids be used, most of the levulose and part of the dextrose is destroyed, and humus substances, acetopropionic and formic acids are produced (Mulder, *J. pr.* 21, 219; Malaguti, *A.* 17, 52; Stein, *A.* 30, 82; Conrad, *B.* 11, 2178; Tollens, *B.* 14, 1951; Sestini, *L. V.* 26, 285; 27, 163; Conrad a. Guthzeit, *B.* 18, 439; 19, 2569 a. 2844; Tollens a. Grote, *A.* 175, 181, 206, 237 a. 233. The inversion of cane sugar cannot be carried out by heating with acids without destroying some levulose (*q. v.*), unless the temperature and quantity of acid be kept within well-defined limits (Jungfleisch a. Grimbart, *C. R.* 108, 144; Wohl, *B.* 23, 2084). Nicol (*Fr.* 14, 180) and Clerget (*A. Ch.* [3] 26, 175) give instructions for the preparation of pure invert sugar. According to the latter, 5 c.c. of strong hydrochloric acid is added to 50 c.c. sugar solution, containing 8.175 g. saccharon, and heated for ten minutes at 68°. Under these conditions the sugar is completely inverted, and the products are unacted upon. They are identical in optical activity and cupric reducing power with the sugar obtained by the action of invertase (see *Action of ferments*) under the most favourable conditions. There is no doubt that invert sugar is a mixture of levulose and dextrose in equal quantities (Jungfleisch a. Grimbart, *C. R.* 108, 144; 107, 390), as its properties agree in every particular with that of a mixture of these two sugars in molecular proportions. Concentrated sulphuric acid dissolves cane sugar at the freezing temperature, without the production of colour, but slight heating causes it to swell up to a black, frothy mass; a blue fluorescent body is formed (Simmmer, *C. C.* 1862, 378). Other acids act in a similar way (Gmelin-Kraut, *Handbuch d. Ch.*; van Kerckhoff, *J. pr.* 69, 48).

**Action of alkalis.** Dilute alkalis do not act on cane sugar in the cold, and but slowly on heating (Michaelis, *J. pr.* 56, 430). By heating with potassium hydroxide and but little water, decomposition takes place, carbon dioxide, acetone, and formic, acetic, propionic, and oxalic acids are formed (Gottlieb, *A.* 52, 122). Potash

or baryta under certain conditions yield a large quantity of lactic acid (Schützenberger, *Bl.* [2] 25, 289). Milk of lime and strontia also decompose cane sugar by prolonged heating (Freymy, *A.* 15, 278; Benedict, *A.* 162, 303; Niederschlag, *Deutsche Zuckerrind.* 1887. 159; Pinner, *B.* 16, 1728).

**Oxidation.** Cane sugar is easily oxidised by almost all the common oxidising agents. Free oxygen does not act on it, but in the presence of platinum black it does; ozone also oxidises it (Gorup-Besanez, *A.* 110, 103). Chlorine or bromine yields gluconic acid, glucose, and other substances (Reichardt, *B. C.* 1880, 559; Grieshammer, *A. Ph.* [3] 15, 193); the same reaction takes place in the presence of lead or silver oxide (Hasiwetz, *A.* Habermann, *A.* 155, 128; Herzfeld, *A.* 220, 353). Iodine and potassium carbonate yield a little iodoform (Millon, *C. R.* 21, 828). The more powerful oxidising reagents—such as strong chromic acid, chlorate of potash, strong sulphuric acid, &c.—act so violently as to cause explosions. Strong nitric acid acts very energetically; dilute nitric acid yields saccharic and oxalic acids; anhydrous nitric acid, or a mixture of strong nitric and sulphuric acids, yields a nitrate (Sobero, *C. R.* 24, 247; Schönbein, *P.* 70, 104; Carey-Lea, *Bl.* [2] 10, 415; Tollens, *B.* 15, 1828; Salkowski, *B.* 15, 1738; Heintz, *A.* 51, 185; *P.* 61, 315; Reinsch, *Jahrb. f. Pharm.* 18, 337; Horneemann, *J. pr.* 89, 304; Tollens, *Chem. Zeit.* 11, 1178). Fehling's solution is not reduced by cane-sugar solution, neither are alkaline solutions of other oxides, except ammoniacal silver solutions, which are reduced slowly in the cold and quicker on warming; but many neutral or acid metallic solutions are reduced (Tollens, *Z. V.* 82, 712; *B.* 15, 1828; Salkowski, *B.* 15, 1738). Dilute chromic acid oxidises cane sugar to oxalic, formic, and carbonic acids; potassium permanganate yields carbonic acid and water; by careful oxidation in the cold, oxalic and formic acids are also produced (Heyer, *Ar. Ph.* [3] 20, 336 a. 430; Brunner, *B.* 12, 549). Maumené (*Bl.* [2] 22, 2; 30, 99) says that three acids, di-, tri-, and hexa-pinic acids  $C_6H_4O_6$ ,  $C_6H_5O_6$ , and  $C_6H_{12}O_6$ , are formed under certain conditions.

**Action of ferments.** Cane sugar is not directly fermentable by organised ferments, with the exception of *Monilia candida*; it requires first to be hydrolysed (inverted), and for this purpose every organism which has the power of assimilating cane sugar produces an organised ferment or enzyme called *invertase*, which first inverts it (Bernard, *Leçons de Physiologie Exper.*, Paris, 1856; Hansen, *Meddelelser*, 1888, 2, 143; Brown, *O. J.* 1886, 173). The action of invertase was first studied by Kjeldahl (*Meddelelser*, 1881, 3, 186); O'Sullivan and Tompson (*O. J.* 1890, 834) have exhaustively investigated the subject. They find the change follows the same time curve as a catalytic reaction; the time necessary to perform a given percentage of hydrolysis varies directly with the amount of invertase; the most favourable concentration of the sugar solution is 20–25 p.c., and the most favourable temperature 55°. Hydrolysis proceeds slowly at the freezing-point; it ceases at about 65°; alkalis immediately stop the reaction, whereas very minute quantities of acid

aid it. Invertase is uninjured by the reaction, and is capable of inverting about twenty-two times its weight of cane sugar per minute for an unlimited period. The dextrose formed is in the bi-rotatory state; on standing, the invert-sugar has the same optical activity as that obtained by the careful action of dilute acids. See also Barth (*B.* 11, 474), Mayer (*B. C.* 1881, 784; 1882, 850), Müller (*Ann. Agronom.* 12, 481), Tamman (*Zeit. phys. Ch.* 3, 25). Invertase acts at a temperature higher than is sufficient to kill the yeast whence it is derived. For production of alcohol, acids, &c., under the influence of organised ferments, see FERMENTATION.

**Compounds with acids.** Nitrosaccharon  $C_{12}H_{18}(NO_2)_2O_{11}$  is prepared by treating the powdered sugar with a mixture of strong  $H_2SO_4$  and fuming  $HNO_3$  in the cold (Schönbein, *P.* 70, 167; Sobero, *C. R.* 24, 247). It is a white doughy mass, insoluble in water, soluble in alcohol and ether. Boiling water decomposes it; m.p. 20°. It is explosive.

With arsenious acid a compound  $C_{12}H_{18}O_{11}.As_2O_3$  is said to be produced. The composition is improbable.

By the action of acetic anhydride and glacial acetic acid, or acetic anhydride and sodium acetate, a series of acetates have been obtained. In these the group  $C_6H_5O$  takes the place of H. We have the monoacetate  $C_{12}H_{18}(C_2H_3O)_2O_{11}$  (Schützenberger a. Nandin, *Bl.* 12, 206); the tetracetate  $C_{12}H_{18}(C_2H_3O)_4O_{11}$ ; the hexacetate (Herzfeld, *N. Z.* 3, 155); the heptacetate (Schützenberger, *Bl.* 12, 204; *C. R.* 61, 485); and the octacetate (Herzfeld, *B.* 13, 267; Démole, *C. R.* 89, 481), all more or less resinous substances, diminishing in solubility in water in proportion to the number of acetyl groups they contain, and increasing in solubility in alcohol and ether with the same change in composition. The octacetate is said to crystallise in needles, m.p. 67°. They are all decomposed by the action of acids and alkalis into acetic acid and the products of the inversion of saccharon. It is probable that by careful treatment with alkalis in equivalent quantities (sufficient to neutralise the acetic acid formed) saccharon is again produced. Benzoyl chloride yields with saccharon a hexabenzozoate  $C_{12}H_{18}(C_6H_5O)_6O_{11}$ , m.p. 109° (Baumann, *B.* 19, 3220; Skrap, *M.* 10, 889).

**Compounds with bases.** By mixing sodium ethylate with a solution of cane sugar and precipitating with alcohol, a compound  $C_{12}H_{24}NaO_{11}$  is obtained (Pfeiffer a. Tollens, *A.* 211, 285). A similar potassium compound has been prepared (Soubeyran, *A.* 43, 223; Brendeeche, *An. Ph.* [2] 29, 73). Cane sugar combines with many bases, forming saccharates which are decomposed into the sugar and carbonate by carbon dioxide, and are but slightly soluble in water. The most important of these are barium saccharate  $C_{12}H_{22}O_{11}.BaO$ , strontium saccharate  $C_{12}H_{22}O_{11}.SrO$ , and  $C_{12}H_{22}O_{11}.2SrO$ , the former produced by mixing solutions of its constituents; it crystallises with 5H<sub>2</sub>O, the latter obtained by bringing together its constituents in boiling solution. Calcium saccharates:  $C_{12}H_{22}O_{11}.3CaO$  3aq is but slightly soluble in water;  $C_{12}H_{22}O_{11}.2CaO$  2aq and  $C_{12}H_{22}O_{11}.CaO$  are soluble in water and decomposed partly by boiling into the tri-saccharate and free sugar,

$C_{12}H_{22}O_{11} \cdot CaO + 2H_2O$ ,  $C_{12}H_{22}O_{11} \cdot 2CaO$ , and  $(C_{12}H_{22}O_{11})_3CaO$  have also been described. Lead acetate alone does not precipitate cane sugar; lead acetate and ammonia yield  $C_{12}H_{22}O_{11} \cdot PbO$ , and  $C_{12}H_{22}O_{11} \cdot PbO_2$ ; iron and copper yield saccharates; it is doubtful if magnesia forms one (Soubeyran, *A. 43*, 223; Stromeyer, *Ar. Ph.* [3] 25, 229; Brendeche, *Ar. Ph.* [2] 29, 73; Pélégot, *J. pr.* 13, 379; 15, 76; *A.* [3] 54, 377; Landolt a. Degener, *Z. V.* 32, 325; Scheibler, *B.* 15, 2945; 16, 985; v. Lippmann, *Organ d. Centr. Ver.* 18, 37; *B.* 16, 2764; Benedict, *B.* 6, 418; Harperath, *Chem. Zeit.* 1886, 323; Boivin a. Loiseau, *C. R.* 58, 60; also old editions of Watts' *Dict.*). Ammonia gas at  $150^\circ$  forms brown amorphous bodies; solutions of ammonia yield similar bodies (Thénard, *C. R.* 52, 444; Payen a. Schützenberger, *Jahresber. f. Zuckerfabr.* 1861-62, p. 191, 192; Laborde, *J.* 1874, 883).

**Compounds with metallic salts.** Several compounds of saccharon with sodium chloride, bromide, and iodide have been prepared (Pélégot, *A.* 30, 71; Maumené, *Bl.* 15, 1; Gill, *C. J.* 1871, 269). Such compounds are  $C_{12}H_{22}O_{11} \cdot NaCl \cdot 2H_2O$ ;  $2C_{12}H_{22}O_{11} \cdot 3NaCl \cdot 4H_2O$ ;  $C_{12}H_{22}O_{11} \cdot NaBr \cdot 1\frac{1}{2}H_2O$ ; and  $2C_{12}H_{22}O_{11} \cdot 3NaI \cdot 3\frac{1}{2}H_2O$ ; the latter is a very stable and definite compound, and is, like the others, easily prepared by boiling a mixture of the sodium salt and saccharon in equivalent quantities, and allowing the solution to stand in a quiet place over sulphuric acid. These bodies form distinct and definite crystals. No definite compounds of the halogen salts of potassium and ammonium with saccharon have been described, but there can be little doubt, from the work of Gill, that such are obtainable. Lithium salts seem to give lithium compounds. Compounds of saccharon with sodium-acetate, nitrate, iodate, and phosphate are not obtainable (Gill, *l.c.*). A double salt of copper sulphate and saccharon,  $C_{12}H_{22}O_{11} \cdot CuSO_4 \cdot 2aq$  crystallises from a saturated solution of the constituents (Barreswil, *J. Ph.* [3] 7, 29). The sodium mercury chloride compound  $2C_{12}H_{22}O_{11} \cdot NaCl \cdot HgCl_2$  crystallises in minute crystals on the slow evaporation of a solution of its constituents in weak alcohol (Boullay, *Bl.* 12, 292). A borax compound  $3C_{12}H_{22}O_{11} \cdot Na_2B_4O_7 \cdot 4H_2O$  has also been described (Stürenberg, *Ar. Ph.* 18, 279). Many other compounds have been described, but they present no material interest.

Saccharon, like many other organic substances, prevents the precipitation of many metals from their solutions by ammonium, sodium, and potassium hydroxide; in some cases the prevention is complete, in others only a portion of the metal is retained in solution (Lussaigne, *C. R.* 14, 691; Groth, *J. pr.* [1] 92, 175; Pellet, *J. Fabr.* 18, 22).

the assimilation of saccharon yields only the production of equal (q. v.).

With phenylhydrazine, milk sugar

lactose and dextrose compounds long known.

**Lactose.** Lacton, lactobiose, and also  $C_{12}H_{22}O_{11} \cdot H_2O(a)$  and  $C_{12}H_{22}O_{11}(\gamma)$  (Schas Sapota).

**Occurrence.** Lactose has been found in the fruit of *Sapotilla* (sheep, goats, and

(Boucharlat, *Bl.* [2] 16, 26). Lactose is found in the milk of women.

*Journal des Fabricants*

cows, 6 p.c. of asses' milk, and a slightly greater proportion of mare's milk (Fleischmann, *Das Milckereiwesen*, Braunschweig, 1875; Kühne, *Lehrb. d. physiol. Ch.* p. 573).

**Preparation.**—Skim milk, or, better, milk from which the fat has been separated by mechanical means, is coagulated with rennet and the whey digested for some time with calcium carbonate (chalk) and aluminium hydroxide. The insoluble matter is then filtered out and the filtrate concentrated in a vacuum to a syrup; this, on standing, yields crystals of lactose. During concentration some matter becomes insoluble; this should be filtered out before final concentration. The crystals are purified by repeated re-crystallisation from solutions concentrated at the temperature of boiling water; on cooling  $C_{12}H_{22}O_{11} \cdot H_2O$  crystallises. This is lactose  $\alpha$ . If the saturated solution is evaporated rapidly on the water-bath with continual stirring, small crystals of  $C_{12}H_{22}O_{11}$  are obtained; lactose  $\gamma$ . These are not hygroscopic. If the  $\alpha$  modification is dried at  $130^\circ$  a hygroscopic mass is left, which is known as the  $\beta$  modification. There are said to be other modifications, but in solution after boiling they all have the same optical activity and are identical (Enling a. Rüf, *B. C.* 1882, 346; *Centbl. f. Ag. Ch.* 1885, 130; J. Kunz, *Ph.* [3] 15, 443).

**Properties.**—Ordinary lactose forms large, rhombic, hemihedral crystals, having a sp.gr. 1.53-1.54 (Schröder, *B.* 12, 562) and containing 1 mol.  $H_2O$ , which is lost by drying at  $130^\circ$ . It is soluble in six parts of cold water and in two and a-half or less of boiling water, from which on cooling it slowly crystallises. Its solutions rotate the plane of polarisation to the right, and its specific rotatory power for the D line is  $[\alpha]_D = 52.53^\circ + (20 - t) \times 0.055$  (Schmöger, *B.* 13, 1927; Hesse, *A.* 176, 98; Erdmann, *J.* 1855, 661; Denigès a. Bonnans, *J. Ph.* [5] 17, 363 a. 411). The variation with the concentration is very little, and, as is obvious from the above formula, the effect of temperature is slight. These numbers for the  $[\alpha]_D$  are calculated for the crystals  $C_{12}H_{22}O_{11} \cdot H_2O$ . For the dry sugar  $C_{12}H_{22}O_{11}$  I have found  $[\alpha]_D = 55.5^\circ$  with a Jellet-Cornu instrument (Schmidt a. Hans, *Ch.*), sodium flame, and absolutely the same number  $[\alpha]_D = 61.6^\circ$  with a Soleil-Scheibler, taking 100 divs. =  $88.4^\circ$ .

$a_1$   $a_D$   
(24.21-67::61.6°:55.5°).  $55.5^\circ - 5.25$  p.c. =  $52.59^\circ$ : my observations were made at  $15.5^\circ$ , Schmöger's at  $20^\circ$ . Freshly-prepared solutions of crystallised lactose exhibit the phenomenon of bi-rotation, the angle immediately after solution being in the proportion of 8.5 to the constant value (Urech, *B.* 16, 2270; Dubrunfaut, *C. R.* 42, 228; Schmöger, *l.c.*; Pareus a. Tollens, *A.* 257, 160). The rotatory power does not vary with the concentration. The dispersive power—that is, the ratio between the specific rotatory powers for the C and D lines—is 1:1.259 ( $[\alpha]_C = 41.58$ ) (Grimbert, *J. Ph.* [5] 16, 295 a. 345). The modification  $\gamma$  when freshly dissolved in water exhibits the phenomenon of semi-rotation—that is, the specific rotatory power is only about  $\frac{1}{2}$  of the normal, to which it attains on standing a few hours (E. O. Erdmann, *Fortschritte der Physik*, 1855, 13; *B.* 13, 2180; Schmöger, *B.* 13, 1915). The modification  $\beta$  on solution has immediately the normal optical activity; the presence of alkali lowers the

activity (Schmögger, *loc. cit.*; Urech, *B.* 17, 1543). Schmögger gives the specific gravity of solutions, containing given percentages of the crystals from which by calculation we get  $D = 3.956$  for a solution containing 2.5 g. dry sugar in 100 c.c. at  $20^\circ$ , 3.921 for a 10 g. solution and 3.913 for a 15 g. one. My observations are, temperature  $15.5^\circ$ :—

1 gram in 100 c.c. sp-gr.	$\frac{15.5}{15.5}$	1.0040; $D = 4.00$
5 grams „ „ „	$\frac{15.5}{15.5}$	1.0199; $D = 3.98$
10 „ „ „	„	1.0397; $D = 3.97$
20 „ „ „	„	1.0785; $D = 3.93$

$D = 3.99$  for solution below 10 g. per 100 c.c. at  $15.5^\circ$ . The  $K = 79.2$  for dry sugar, *i.e.* 0.5723 anhydrous lactose reduce 1 g. CuO from Fehling's solution (Jones, *Analyst*, 1889, 81). According to Soxhlet 0.5 g. sugar = 74 c.c. Fehling's solution, hence  $K = 74$ ; in this case 1 g. CuO = 6127 lactose: by weighing the precipitated CuO as Cu by Allihn's method, 1 g. sugar = 1.736 CuO, or 1 g. CuO = 0.5760 g. sugar,  $K = 78.8$ , agreeing with the number given by Jones. According to Roderwald a. Tollens (*B.* 11, 2076) the working number 1 g. CuO = 5795 g. anhydrous sugar. I am inclined, when the conditions hereafter to be described are followed, to place the  $K$  at 78.9, *i.e.* 1 g. CuO = 0.5758 g. sugar. In this case 7.5 mols. CuO are reduced by 1 mol. sugar.

**Action of heat.** Hydrus crystallised lactose (a) remains constant at  $100^\circ$ ; above this water is slowly given off, and at  $130^\circ$  the dehydration is complete without decomposition if the water is eliminated slowly. Anhydrous lactose commences to colour at  $170^\circ$ – $180^\circ$ , loses water, and forms the so-called lactocaramel  $C_{12}H_{20}O_8$ , which is easily soluble in water but insoluble in alcohol, and yields compounds with lead and copper oxide. Lactose melts at  $203.5^\circ$  to a brown liquid, and by further heating it is decomposed with separation of carbon (Lieben, *J. pr.* 68, 409). Heated in a sealed tube with water to  $90^\circ$ – $100^\circ$  it is coloured, and more so at  $180^\circ$ – $200^\circ$ , when a glucose is produced which may be precipitated by alcohol, and, by further heating, carbonic acid, a little pyrocatechin, and other bodies are formed (Vohl, *A.* 105, 334; Hoppe-Seyler, *B.* 4, 16; Munk, *II.* 1, 357).

**Action of acids.** By heating with dilute acids lactose is hydrolysed (inverted), yielding galactose and dextrose

one molecule of water being taken up. The reaction takes some hours to complete; during the hydrolysis the reducing power and optical activity increase (Pasteur, *C. R.* 42, 228; Fudakowski, *B.* 8, 559; 9, 42; 278 and 1602; 11, 1069; Bourquelot, *N. Ztschr. f. Rubenz-ind.* 16, 71; Kent a. Tollens, *A.* 227, 221; Rindell, *N. Ztschr. f. Rubenz-ind.* 4, 163). The chief products of the reaction are as stated, but the conditions have not yet been described by which the optical activity and  $K$  of the resulting substances will exactly correspond with those of a mixture of equal parts of galactose and dextrose. Other bodies are undoubtedly produced. By the continued action of acids for several days, aceto-propionic and formic acids are produced (Tollens a. Roderwald, *A.* 206, 231; Conrad a. Guthzeit,

*B.* 19, 2575). Concentrated sulphuric acid does not blacken lactose in the cold.

**Compounds with acids.** A mixture of sulphuric and nitric acids give lactose pentanitrate  $C_{12}H_{17}(NO_3)_5O_{11}$ , insoluble in water but soluble in alcohol and ether, m.p.  $139.2^\circ$  and exploding when struck by a hammer on an anvil; lactose tri-nitrate  $C_{12}H_{19}(NO_3)_3O_{11}$ , very slightly soluble in water, but easily in alcohol and ether, m.p.  $37^\circ$ ; and lactose tetranitrate  $C_{12}H_{18}(NO_3)_4O_{11}$ , m.p.  $80^\circ$ – $81^\circ$  (Gé, *J. R.* 1882, 253; *B.* 15, 2238). With chlorosulphonic acid lactose yields dextrose-tetra-sulphonic acid chloride (Claesson, *J. pr.* [2] 20, 1 and 18). Organic acids act very slowly on lactose, but by prolonged action they yield ethers of lactose or of dextrose and galactose (Berthelot, *Chim. org.* 2, 279, 295). A series of acetates, beginning with the mono-body and ending with the octo-one, have been described.  $C_{12}H_{21}(C_2H_3O)_8O_{11}$  is obtained by boiling lactose with an excess of acetic anhydride or by heating a mixture in the proper proportions of the sugar, acetic anhydride, and fused sodium acetate at  $100^\circ$  (Herzfeld, *B.* 13, 265). This body is insoluble in water and in ether, soluble in benzene, acetic acid, and in alcohol. It crystallises from a mixture of alcohol and acetic ether.  $[\alpha]_D = +31^\circ$  in alcoholic solution. The mono- and di- acetate are obtained by incompletely decomposing the octo-acetate by alkalis (Démole, *C. R.* 89, 481). Tetracetate is formed at the same time as the octo- acetate, when lactose is boiled with acetic anhydride (Schützenberger a. Naudin, *Bl.* 12, 208). It is easily soluble in water,  $[\alpha]_D = +50^\circ$ . Hexacetate  $C_{12}H_{16}(C_2H_3O)_6O_{11}$  crystallises from a mixture of alcohol and acetic ether in white needles, m.p.  $86^\circ$  (Herzfeld, *N. Z. R.* 3, 156). It is doubtful whether or not lactose is reproduced when these bodies are saponified by treatment with alkalis. There seems to be no reason why it should not be so, if the alkali is carefully employed.

**Action of alkalis.** Hot alkalis colour solutions of lactose yellow to brown, and form lactic acid, pyrocatechin, and other products (Hoppe-Seyler, *B.* 4, 317; Nencki a. Sieber, *J. pr.* [2] 34, 503; Urech, *B.* 17, 1543). Fused with KHO it yields carbonic, oxalic, and a little succinic acids (Hlasiwetz a. Barth, *A.* 138, 76).

**Compounds with alkalis.** Lactoseates are formed by the action of potash or soda on lactose in alcoholic solutions, or by adding alcohol to the mixed aqueous solutions. They are amorphous, easily decomposed precipitates having a composition expressed by the formulæ  $C_{12}H_{21}NaO_{11}$  and  $C_{12}H_{21}KO_{11}$  (Fromy, *A.* 15, 278; Hönig a. Rosenfeld, *B.* 12, 45). Calcium, barium, and lead lactoseates are obtained by dissolving the base in lactose solution and precipitating with alcohol. The long-continued action of lime produces isosaccharin and metasaccharin (Cuisinier, *M. S.* [3] 12, 520; Kiliani, *B.* 16, 2625). By heating with ammonia, brown, amorphous, nitrogenous products are obtained (Thénard, *C. R.* 52, 444). Aniline yields two crystalline compounds,  $C_{10}H_{19}NO_{21}$  and  $C_{10}H_{19}N_2O_{20}$ , which reduce Fehling's solution (Sachsse, *B.* 4, 835; *L. V.* 16, 441).

**Oxidation.**—Oxygen and ozone have no action on lactose in the cold; hot solutions are oxidised by oxygen in the presence of platinum black (Gorup-Besanez, *A.* 110, 86 a. 103; Reiset

a. Millon, *A. Ch.* [3] 8, 236). Alkaline permanganate solutions oxidise lactose easily (Laubenheimer, *A.* 164, 289). Chromic acid yields aldehyde (Guckelberger, *A.* 64, 98). Nitric acid first inverts lactose and then yields mucic and saccharic acids; from 86 to 40 p.c. of mucic acid is produced; by long-continued heating tartaric and oxalic acids, &c., are obtained (Liebig, *A.* 113, 1; Dubrunfaut, *C. R.* 42, 228; Kent, *A.* Tollens, *A.* 227, 227). Alkaline solutions of copper oxide are reduced by lactose, and from amongst the products of the reaction Bödecker a. Struckmann (*A.* 100, 264) isolated gallactonic acid  $C_7H_{10}O_6$ ; pectolactonic acid  $C_{10}H_{16}O_{12}$ , lactic and glycollic acids are also produced (Habermann a. Hönig, *B.* 17, 351). Silver oxide oxidises lactose solutions with production of oxalic, glycollic, and lactonic (galactonic) acids (Killani, *B.* 13, 2307). Chlorine or bromine in the presence of silver oxide yield lactonic (galactonic) acid  $C_6H_{10}O_7$  (Barth a. Hlasiwetz, *A.* 119, 281; 122, 96). By very careful oxidation with bromine water Fischer a. Meyer (*B.* 22, 361) have obtained lactobionic acid  $C_{12}H_{22}O_{17}$ ; it is a colourless, strongly acid syrup, easily soluble in water, but only sparingly in alcohol. It does not reduce Fehling's solution; it decomposes metallic carbonates, forming salts. The calcium ( $C_{12}H_{21}O_{17}/2$ ), Ca, barium ( $C_{12}H_{21}O_{17}$ ), Ba, lead ( $C_{12}H_{21}O_{17}$ ), Pb, and other salts may be prepared in this way; they are insoluble in alcohol, but soluble in water. When heated with dilute mineral acids, lactobionic acid is decomposed into galactose and gluconic acid. With iodine and sodium bicarbonate lactose yields a little iodoform (Millon, *C. R.* 21, 828).

**Fermentation.**—There is no known enzyme capable of inverting lactose; it does not ferment with yeast (Berthelot, *A. Ch.* [3] 50, 332 a. 362; Fitz, *B.* 11, 42). It easily undergoes lactic acid fermentation, especially in milk (Fitz, *l.c.*; Richet, *C. R.* 86, 550; Schmidt-Mülheim, *B.* 15, 2631). It undergoes alcoholic fermentation in kumys or kefir fermentation (Struve, *B.* 17, 314; Vieth, *A.* 12, 2), and also under the agency of certain bacteria (Rotondi a. Zechini, see v. Lippmann, *Deutsche Zuckerind.* 1887, 1091).

Phenylhydrazine yields lactose phenylhydrazide  $C_{17}H_{24}O_{10}N_2$ , soluble in water and alcohol, insoluble in ether and lavoratory, and lactose osazone  $C_{17}H_{22}N_2O_8$ , crystallising in yellow needles; soluble to some extent in hot water, and m.p. 200° (Fischer, *B.* 17, 583; 20, 830; 20, 2566). By the action of hydrochloric acid it yields lactose osone (Fischer, *B.* 21, 2631).

**Maltose.** *Maltobiose*, *Amylon*,  $C_{12}H_{22}O_{11}$ ;  $C_{12}H_{22}O_{11} \cdot H_2O$ . De Saussure (*Bibl. Britannique*, 56, 1814, 333; *P.* 1819, 29, 58) may have obtained this sugar when studying the products of the spontaneous decomposition of starch-paste when exposed to the air at 20°–25°. Guérin-Varry (*A. Ch.* 60, 32; 61, 66) described accurately how the body could be prepared in the crystallised state and some of its properties, but failed to recognise it as a distinct substance; Jacquelin (*A. Ch.* 63, 187) added nothing to Varry's work; Dubrunfaut (*A. Ch.* [3] 21, 78) prepared the body according to Varry's method, observed that it was less soluble in alcohol than dextrose, and had an optical activity three times as great, *ee*,  $[\alpha]_D = 58 \times 3 = 174$ , a figure so high as to lead

one to believe that he had not a pure body in his hands. He recognised it as a distinct body, and called it *maltose*; he, however, looked upon it as a glucose, *triglucoase*; O'Sullivan (*C. J.* 1872, 576; 1876, 478) showed that it was not an 'ose' but an 'on' sugar, and from this and a fuller description of its characters gave it a place among chemical entities.

**Occurrence.**—It is present in some commercial glucoses and in beer (Valentin, *J. S. A.* 24, 404); probably in bread; in *amé*, a rice-extract prepared in Japan (Yoshida, *C. N.* 43, 29), and in germinated cereals to the extent of 1 to 2 p.c. (O'Sullivan, *C. J.* 49, 58). After feeding with amylaceous substances it is found in the intestinal canal, but the blood of the mesenteries contains only dextrose. If injected into a vein it is found in the urine; if injected subcutaneously, it is partially converted into dextrose (Phillips, *B. C.* 1882, 127). Some of the reducing sugars of blood may be maltose.

**Formation.**—Diastase converts starch and the dextrins into maltose (O'Sullivan, *l.c.*). The ferment of saliva, ptyalin, of the pancreas, and of the liver, act in the same way (Nasse, *J. Th.* 1877, 62; Musculus a. v. Mering, *Z.* 2, 403). The same ferments act on glycogen, maltose being amongst the products; dextrose is present when saliva is employed (Kütz, *Pf.* 24, 8). All mineral acids and many organic acids act on starch and glycogen; maltose is amongst the products.

**Preparation.**—100 g. purified starch are mixed as completely as possible with 300 c.c. water at 40°, and then poured with continuous stirring into 2 litres of boiling water. The paste is cooled to 60° and the extract from 20 g. pale malt added to it; the mixture is kept at 60°–63° for four or five hours, and the solution may be allowed to cool and stand for a few days. At the end of that time it is evaporated, best in a vacuum, to 200 c.c., and then boiled with 2 litres alcohol, sp.gr. 820. On cooling and standing, the clear liquid is decanted off the undissolved syrup and put aside in a corked flask; at the end of six days the sides of the flask will be found to be covered with a crystalline crust of maltose. Or the undissolved syrup may be treated with strong alcohol as long as any matter is taken up, the whole of the clear alcoholic solutions are mixed, the alcohol distilled off and the residue concentrated to a syrup; this on standing in a cool place becomes filled with crystals of maltose, especially if a few crystals from a previous preparation be stirred in. These may be washed with dry methyl alcohol; if this is used hot, a portion of the crystals dissolves and the solution soon yields much sugar. The crystallisation is hastened by adding half a volume of ethyl alcohol (810 sp.gr.) or a little ether with some crystals of a previous preparation (O'Sullivan, *l.c.*; Schulze, *B.* 7, 1047; Soxhlet, *J. pr.* [2] 21, 277; Hertzfeld, *A. Ch.* 220, 209; Cuisinier, *J.* 1884, 1803). The body may be purified by recrystallisation from methyl alcohol or water.

**Properties.**—Maltose crystallises out of water in plates which contain  $C_{12}H_{22}O_{11} \cdot H_2O$ ; out of alcohol (sp. gr. 810) it crystallises in crusts and at times in cauliflower-like or warty aggregations which contain  $C_{12}H_{22}O_{11}$ . The hydrous body easily parts with its water at 100° in a

current of dry air. The anhydrous body is but slightly soluble in strong ethyl alcohol; it is more soluble in methyl alcohol. The hydrous body dissolves more freely in both solvents. Both bodies are very soluble in water, but less so than dextrose. The solution is optically active, and the activity for a solution containing 10 g. in 100 c.c. is  $15^{\circ}$ - $20^{\circ}$  less when freshly prepared than after standing. The activity becomes constant in ten to twelve hours in the cold or immediately on boiling (Meissel, *J. pr.* [2] 25, 120).

The specific rotatory power for dry maltose is  $[\alpha]_D = 154^{\circ}$ - $155^{\circ}$ ,  $[\alpha]_D = 139^{\circ}$ - $140^{\circ}$  at  $15.5^{\circ}$  in solutions containing 10 g. per 100 c.c. and under (O'Sullivan, *C. J.* 35, 771; 45, 5); Meissel (*J. pr.* [2] 25, 114) gives the formula  $[\alpha]_D = 140.735 - 0.1837 P - 0.95 T$  to represent the specific rotatory power of dry maltose at  $0^{\circ}$ , in which  $P$  = percentage of maltose in solution and  $T$  the temperature of observation. On calculating the value of the sugar in a 10-g. solution at  $15.5^{\circ}$  from this formula we get  $[\alpha]_D = 138.9$  (v. also Soxhlet, *l.c.*, and Herzfeld, *A.* 220, 206). The dispersive power, i.e. the ratio of  $[\alpha]_D : [\alpha]_C$ , is 1.262 (Grimbert, *J. Ph.* [5] 16, 295). A solution of maltose containing 10 g. dry substance in 100 c.c. at  $15.5^{\circ}$  has a sp. gr.  $\frac{15.50}{15.50} = 1.0395$ . Maltose reduces alkaline copper solution. O'Sullivan (*C. J.* 35, 771) gives its reducing power  $K = 62.5$ , i.e. 62.5 parts dextrose reduce as much copper oxide as 100 parts of maltose. Soxhlet (*J. pr.* 21, 227-317) says 0.5 g. maltose in 1 p.c. solution = 64.2 c.c. undiluted Fehling solution (1 c.c. = 0.05 g. dextrose), i.e.  $K = 64.2$ , and 67.5 c.c. if the solution is diluted with four times its volume of water, i.e.  $K = 67.5$ . He further states that 100 parts of dry maltose = 113 parts Cu, hence 141 parts CuO; from this, we have  $K = 63.94$ . There appears to be fair evidence that the  $K$  varies within certain limits according to the mode of manipulation, but when we see that the  $K$  should be 63.17 if it be supposed that 1 molecule maltose reduces 6 molecules CuO, and that the observed numbers closely approach this, we may take it that this is the true number when errors of manipulation are avoided. If the  $Cu_2O$  be separated, the filtrate treated with acid gives a further reduction with Fehling's solution which, if added to the first, equals the reduction of dextrose (Herzfeld, *A. B.* 589, 220). Alkaline mercuric cyanide solutions are also reduced by maltose. Copper acetate is not reduced by it (Barfoed, *Org. Analysis*, 214); dextrose reduces this reagent. When maltose reduces copper oxide, glycollic and a mixture of acids of unknown composition are produced (Habermann a. Hönig, *M.* 5, 208).

Maltose is hydrolysed to dextrose according to the equation  $C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6$  by the following reagents: the mineral acids and many organic ones; pancreatic secretion and portions of the small intestine (Brown a. Heron, *C. N.* 42, 83; Bourquelot, *C. R.* 97, 1000 and 1922); a ferment developed in *Aspergillus niger* and in *Mucor mucedo*; the former contains also a ferment capable of inverting sucrose, the latter yields only the one (Bourquelot, *l.c.*). Under the action of ordinary beer yeasts malt-

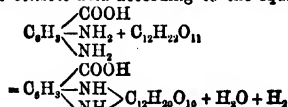

ose ferments, i.e. is broken down into carbonic acid, alcohol, &c., apparently without being previously inverted. Other organisms yield lactic acid and other products; v. FERMENTATION.

Maltose withstands the hydrolytic action of sulphuric acid with five times the power of sucrose; 3 hours' digestion with a 3 p.c. solution gives complete inversion (Meissel, *l.c.*). 0.5 p.c. solution of lactic acid does not hydrolyse it, even at  $110^{\circ}$ ; 1 p.c. oxalic acid acts at that temperature; carbonic acid at  $100^{\circ}$ , and under a pressure of six atmospheres, is without action (Bourquelot, *J. de l'Anat. et de la Physiol.* 22, 161-204; Urech, *B.* 18, 3074).

Nitric acid converts maltose into saccharic acid and finally oxalic acid. Chlorine does not act on it as energetically as it does on dextrose or sucrose; the product is neither gluconic nor glycollic acids (Meissel, *l.c.*). Herzfeld (*B. C.* 1883) obtained an acid which he called maltonic acid, by the action of bromine on maltose; this is probably identical with Fischer and Meyer's (*B.* 22, 194) *maltobionic acid*  $C_{12}H_{22}O_{12}$ , which they prepared by acting on maltose in aqueous solution with bromine in the cold for two or three days. This acid is broken down into dextrose and gluconic acid by digestion with sulphuric acid. Treated at  $110^{\circ}$  with acetic anhydride and acetic acid, maltose yields *monacetyl maltos*  $C_{12}H_{21}(C_2H_3O)_O$  (Yoshida, *l.c.*, a. Steiner, *G. N.* 43, 52); with sodium acetate and acetic anhydride the *octacetyl* derivative  $C_{12}H_{11}(C_2H_3O)_8O$  is produced, the optical activity of which is  $[\alpha]_D = 81.18^{\circ}$  (Herzfeld, *A.* 200, 206). With benzyl chloride it yields penta-benzyl maltose, m.p.  $110^{\circ}$ - $115^{\circ}$  (Skraup, *M.* 16, 359).

Sodium  $C_{12}H_{21}NaO_{11}$ , calcium  $C_{12}H_{19}CaO_{11}$ , strontium  $C_{12}H_{19}SrO_{11}$ , and barium  $C_{12}H_{19}BaO_{11}$  maltose are prepared as easily decomposable amorphous precipitates when alcoholic solutions of maltose and the corresponding bases are mixed (Herzfeld, *l.c.*). Compounds with the alkaline chlorides or bromides have not been prepared.

When 1 part maltose, 2 parts phenylhydrazine hydrochloride, 3 parts sodium acetate, and 15 parts of water are heated together for  $1\frac{1}{2}$  hours, *phenylmaltosazone* crystallises out on cooling in fine yellow needles, m.p.  $190^{\circ}$ - $191^{\circ}$ . The equation  $C_{12}H_{22}O_{11} + 2N_2H_2 \cdot C_6H_5 = C_{12}H_{22}N_2O_8 + 2H_2O + H_2$  represents the reaction. Only 30 p.c. of the maltose employed is obtained as *osazone* (Fischer, *B.* 17, 593). With  $\gamma$ -diamido-benzoic acid, maltose yields *malto- $\gamma$ -diamido-benzoic acid* according to the equation

The body crystallises in white microscopic needles or narrow plates; its barium salt is a gummy mass (Griess a. Harrow, *B.* 20, 2212).

Isomaltose. Fischer (*B.* 23, 3687) prepared a saccharon by the polymerisation of dextrose. Previous attempts in this direction had been made by Musculus (*B.* 18, 66), Musculus a. Meyer (*J. R.* 92, 528), Hönig a. Sehuber (*M.* 7, 455), and they obtained by the action of strong sulphuric acid a dextrin-like body  $C_6H_7O_6$ .

which slightly reduced Fehling's solution, did not ferment with beer yeast, and was reconverted into dextrose by the action of dilute sulphuric acid. Grimaux a. Lefèvre (*C. R.* 103, 146) obtained a like result by evaporating *in vacuo* dextrose with dilute hydrochloric acid. Gautier (*Bl.* 22, 145) obtained a body  $C_{12}H_{22}O_{11}$  by the action of hydrochloric acid on an alcoholic solution of dextrose; this body reduces Fehling's solution but slightly, does not ferment with beer yeast, and could not be reconverted into dextrose. Grimaux and Lefèvre considered that in their product they could detect maltose by the osazone. Scheibler a. Mittelmeier (*B.* 23, 8075; 24, 301) isolated an unfermentable syrup from commercial glucose which reduces Fehling's solution and yields an osazone  $C_{12}H_{22}N_2O_8$ , m.p. 152°–153°. They find it is only produced when the heating with acid has been prolonged, and that it may be prepared by the action of acids on dextrose. This body has been previously named gallisin (Cobenzl, Roseneck a. Schmitt, *B.* 17, 1000 and 2456; Anthon, *D. P. J.* 151, 213; Mehring, *Deutsche Vierteljahrsschrift für öffentl. Gesundheitspflege*, 14, Heft 2). Fischer's substance also yielded the same osazone, m.p. 150°–153°; he calls the body isomaltose, and prepares it as follows: One hundred g. glucose (commercial dextrose) are digested with 400 g. hydrochloric acid solution sp. gr. 1.19 at 10°–15° for 15 hours. Alcohol throws out of the solution a small precipitate, which is not formed if the temperature of the reaction is kept below 10°. To the clear solution an excess of ether is added, when a colourless amorphous precipitate is obtained which is filtered out and washed with a mixture of alcohol and ether. This body is dissolved in water, neutralised, boiled to expel alcohol and ether, and fresh beer yeast added. After 18 hours all the dextrose is destroyed (?); the solution has still a high reducing power, and contains isomaltose and other bodies.

The isomaltose is separated as osazone; the solution is heated with phenylhydrazineacetate in the water-bath for 1½ hours. A little glucosazone separates and is filtered out, and on cooling the filtrate deposits a yellow precipitate consisting of a mixture of glucosazone and isomaltosazone; the mother-liquor, by further heating and similar after-treatment, yields more osazone. The whole of the osazone obtainable is boiled with 100 c.c. water and the solution filtered, the filtrate contains isomaltosazone, which is deposited on cooling in needles; 2½ g. of this are obtained from 100 g. glucose, the actual yield is, no doubt, considerably higher than this. By the action of hydrochloric acid the osazone is converted into the osone, which, when boiled with 4 p.c. hydrochloric acid, yields glucosone and glucose.

Lintner claims to have found isomaltose amongst the transformation products of starch by diastase (*Woch. Brauerei*, 9, 245), and in wort and beer (*Zeit. ges. Brauw.* 1891, 281), but it is very doubtful if this is the same body as that above described. Schiffer (*C. C.* 1892, 2, 825) has also isolated isomaltose from the diastase transformation products of starch. But the whole evidence is unsatisfactory, as the factors upon which the identity of the bodies can be recognised are not stated. Lintner and Düll (*Zeit. ges. Brauw.* 1892, 145) prepare it as fol-

lows: 250 g. potato starch are mixed with 500 c.c. diastase solution at 55° containing 0.5 g. diastase (*J. pr.* 34, 378) and 2 litres water at 75°C. After complete solution another 0.5 g. diastase is added, and the reaction allowed to proceed for three hours at 65°–69°.  $[\alpha]_D = 170^\circ$ . for matter in solution. The solution is evaporated to a syrup, saturated with 80 p.c. alcohol, and poured into hot alcohol. Sufficient alcohol must be used so that every 100 parts of 80 p.c. alcohol do not contain more than 10 pts. dry substance. After cooling, the clear solution is decanted and the alcohol distilled off. The residue is diluted to a 20 p.c. solution and yeast added in order to destroy the maltose; this is found to take place in about 20 hours. The fermented solution is filtered, decolourised with animal charcoal, evaporated to a syrup, and precipitated with 85 p.c. alcohol; there must be 100 c.c. of 85 p.c. alcohol for every 5 g. of dry substance. The solution is evaporated and the syrup treated in the same way, but with 99 p.c. alcohol and so that 100 c.c. of alcohol are present for every 3 g. dry substance. The clear alcoholic solution contains isomaltose and but a trace of dextrin, which may be removed by fractionating with alcohol. In this way 20 p.c. of the starch is obtained as isomaltose.

Lintner (*Zeit. ges. Brauw.* 1892, 6) finds the reducing power of iso-maltose to be 84 p.c. of that of maltose, i.e.  $K = 53.1$ , and its optical activity to be  $[\alpha]_D = 189^\circ$ . He has not been able to crystallise it, and finds it under certain conditions fermentable by yeast and converted by diastase into maltose (*Zeit. ang. Ch.* 1892, 263).

**Trehalose.**  $C_{12}H_{22}O_{11} \cdot H_2O$ .

**Occurrence.**—It has been isolated from ergot of rye (Wiggers, *A.* 1, 173; Mitscherlich, 56, 15); trehala-manna, the hollow cocoons of the larvæ of an insect (*Larinus maculatus*) (Berthelot *A. Ch.* [3] 53, 232; 55, 272 and 291); and from various fungi (Müntz, *C. R.* 76, 649). Berthelot at first considered it a new sugar and called it *trehalose*, but afterwards found it was identical with the mycose of Mitscherlich, and the *Saccharum spermodia* of Wiggers.

**Preparation.**—Any one of the materials mentioned is extracted with boiling alcohol of moderate strength; the alcohol is distilled off the clear solution. The residue is taken up with water and precipitated with basic lead acetate. The precipitate is washed with water and pressed; it is then suspended in water and submitted to a current of  $H_2S$ . The clear filtrate from the lead sulphide is evaporated to a syrup, when the sugar crystallises and can be purified by recrystallisation. I may say that I do not find this mode of treatment answer very well; the filtrate from the  $PbS$  is, no doubt, clear, but the precipitate with the lead salt is bulky and unwieldy. I much prefer in this case, as in others of the same kind, fractional precipitation with alcohol; a few experiments will show the strength of alcohol best suited to holding or precipitating the sugar. (See also Apping.)

**Properties.**—The sugar crystallises in rhombs ( $C_{12}H_{22}O_{11} \cdot H_2O$ ); it gives up its water at 100°, m.p. 109°; it is sweet, easily soluble in water and boiling alcohol, insoluble in ether. Specific rotatory power in aqueous solutions

$[\alpha]_D = 199^\circ$  (Berthelot);  $[\alpha]_D = 192.5^\circ$  (Mitscherlich);  $[\alpha]_D = 197.28^\circ$  (Apping). These factors are unsatisfactory, and cannot be relied on to identify the sugar. It does not reduce Fehling's solution. Acids convert it very slowly into dextrose (Berthelot), there being no other product; but considering that five hours are required for complete hydrolysis, it is not possible that only pure dextrose could be formed. With strong nitric acid it yields a nitro-compound; with weaker acid no mucic acid is formed, but saccharic acid and finally oxalic acid. With acetic and butyric anhydrides it yields compounds identical with those produced from dextrose. Maquenne (*C. R.* 112, 947) says acetic anhydride yields  $C_{12}H_{22}(C_2H_3O)_2O_{11}$ . Alkalis do not act on it. On adding basic lead acetate, or an ammoniacal solution of the acetate, to its solutions a lead compound is precipitated. It appears to slowly undergo alcoholic fermentation in contact with beer yeast, but this has not been established with certainty. Phenylhydrazine does not form a compound with trehalose (Fischer, *B.* 17, 583).

**Agavose**  $C_{12}H_{22}O_{11}$  (?) is obtained from the juice of *Agava americana*; it is crystalline, soluble in water, and optically inactive (?). It is hydrolysed to a sugar or mixture of sugars  $[\alpha]_D = -14.4^\circ$ . It reduces Fehling's solution;  $K = 62.5$ , agreeing nearly with maltose in this respect. It does not yield mucic acid on treatment with nitric acid. It is probably fermentable under the influence of some saccharomyces and yields alcohol, &c. (Michaud a. Tristan, *Ann.* 14, 548).

**Cyclamose**  $C_{12}H_{22}O_{11}$ . A sugar obtained from *Cyclamen europaeum*, having a levorotation  $[\alpha]_D = -15.15^\circ$  or  $-11.4^\circ$ ; it is hydrolysed by dilute acids, when the levorotation increases to  $[\alpha]_D = -66.54^\circ$  (Michaud, *C. N.* 53, 232).

**Parasaccharose**  $C_{12}H_{22}O_{11}$ . This, together with another uncrystallisable sugar, is said to be obtained from cane sugar by the action of a yeast (Jodin, *C. R.* 53, 1252). It crystallises easily, and is easily soluble in water and difficultly in alcohol. It is dextrorotatory, having  $[\alpha]_D = 108^\circ$ , and it reduces Fehling's solution;  $K = 50$  (about). Hot dilute sulphuric acid does not act on it, whilst hot dilute hydrochloric acid diminishes the optical activity and increases the  $K$ . On long digestion the solution becomes brown, and finally complete decomposition takes place.

**Melibiose**  $C_{12}H_{22}O_{11}$  is obtained by the careful hydrolysis of raffinose by acids or invertase (see *Raffinose*). Its specific rotatory power is  $[\alpha]_D = +126.8^\circ$ . It forms a hydrazone  $C_{12}H_{22}O_{11}N$  as yellow microscopic crystals, m.p.  $145^\circ$ , and an octacetyl derivative  $C_{12}H_2O_{11}Ac_8$  (Scheibler a. Mittelmeier, *B.* 23, 1438). Invertase converts it into galactose and dextrose.

**Tewinkose**  $C_{12}H_{22}O_{11}$  occurs in the milk of the gamoose (*Bos Bubalus*). It is prepared by precipitating the milk by 4 p.c. acid mercuric nitrate (Wiley, *Am. G.* No. 5 (?), neutralising the filtrate with NaHO, filtering out the precipitate, separating the mercury from filtrate by  $H_2S$ , and concentrating the slightly acid solution to the crystallising point. A slight precipitate formed during evaporation must be separated. It is purified by two or three recrystallisations. The solutions are dextrorotatory,  $[\alpha]_D = 48.6^\circ$ ; it

reduces Fehling's solution;  $K = 73.6$ , hence less than lactose; if 7 molecules CuO were reduced by 1 molecule of sugar, the  $K$  would be 73.4, a near approximation; and  $D = 3.94$  for the crystals, hence they are anhydrous. Acids hydrolyse it very easily, the only product being dextrose (Pappel a. Richmond, *C. J.* 1890, 758). The substance is, no doubt, an '-on' sugar  $C_{12}H_{22}O_{11}$ , and is, like amylo-, di-dextrose, and should not therefore yield mucic acid on treatment with nitric acid.

#### (c) *Trihexoses.*

**Raffinose**  $C_{18}H_{32}O_{16} \cdot 5H_2O$ , first obtained from a Tasmanian *Eucalyptus manna* by Johnston (*C. J.* 1, 159). This was the *melitose* of Berthelot (*A. Ch.* [3] 46, 66), who now says (*C. R.* 103, 533) that this term should be applied only to a loose combination of raffinose with eucalin, which is decomposed by re-crystallisation. From the evidence it would appear that the body first described as melitose was impure raffinose, and that the impurity even was not eucalin. It occurs also in cotton seed (Berthelot, *l.c.*; Ritthausen, *J. pr.* [2] 29, 357; Böhn, *J. pr.* [2] 30, 37); in beetroot (Loiseau, *C. R.* 82, 1058; Tollens, *A.* 232, 169; *B.* 18, 26; Rischbieth a. Tollens, *A.* 232, 172; *B.* 18, 2611); in beet juice (v. Lippmann, *B.* 18, 3087); in barley (O'Sullivan, *C. J.* 1886, 70); in young wheat-buds (Richardson a. Crampton (*B.* 19, 1180); and again in *Eucalyptus manna* (Tollens, *A.* 232, 201); probably also in Soja beans. Loiseau considered it a product of the refining process, but v. Lippmann that it was ready formed in beet juice.

**Preparation.**—A molasses containing a fair quantity of raffinose is selected, and the chief part of the cane sugar removed as monostrotium saccharate; on heating the solution raffinose and cane sugar bistrontium saccharates are precipitated. The compounds are decomposed by  $CO_2$  and the sugar solution obtained again precipitated with strontia, when the cane sugar is precipitated as monostrotium saccharate, and raffinose remains in solution and may be purified by crystallisation (Scheibler, *B.* 18, 1409). Raffinose may be extracted from cotton-seed cake and *Eucalyptus manna* by alcohol, and purified by crystallisation. See also Tollens (*l.c.*); Tenne (*Zeit. d. Ver.* 31, 795); Schaaf (*Z. V.* 33, 699); Wolff (*Deutsche Zuckerind.*, 1887, 1418); Berthelot (*l.c.*); Lindet (*C. R.* 110, 795); Gunning (*C. C.* 1891, ii, 798).

**Properties.**—Raffinose crystallises in cauliflower-like segregations consisting of thin microscopic rhombic prisms, which contain  $C_{18}H_{32}O_{16} \cdot 5H_2O$ . The  $H_2O$  is in greater part eliminated in a vacuum over sulphuric acid, and the remainder easily at  $100^\circ$  (O'Sullivan). If heated too quickly it melts, and then cannot be dried without decomposition. Berthelot obtained crystals containing  $6H_2O$  (*C. R.* 109, 548; Scheibler, *B.* 18, 1779; Rinne in *Rischbieth Dissert. über Raffinose*, Göttingen, 1885). It is easily soluble in water, very slightly in strong alcohol, and slightly in methyl alcohol, being much more soluble than cane sugar in this solvent. The dry sugar melts at  $118^\circ$ – $119^\circ$  (Scheibler, *B.* 19, 2868). Its solutions are optically active, the specific rotatory power of crystallised raffinose for the D line being  $[\alpha]_D = 104.5^\circ$  in 10 p.c. solution;  $[\alpha]_D = 114.7^\circ$  or  $[\alpha]_D =$

185.1° for the dry sugar. O'Sullivan observed  $[\alpha]_D = 185.8^\circ$ . No bi-rotation has been observed. It does not reduce Fehling's solution.  $D = 8.712$  (Tollens, *B.* 18, 2616), but this is due to some misunderstanding;  $D = 8.956$  (O'Sullivan, *C. J.* 1886, 70).

**Action of acids.** Hot dilute acids hydrolyse raffinose; galactose, levulose, and probably dextrose are formed (Hädicke a. Tollens, *Z. V.* 37, 17; *A.* 238, 308; Beythien a. Tollens, *A.* 255, 214; Maquenne, *C. R.* 112, 799). By very careful hydrolysis, Scheibler a. Mittelmeier (*B.* 22, 1678) have obtained a saccharose and levulose as the products of the reaction; the saccharose is a new body, which they have called *melibiose* (*q. v.*). The mixture of saccharose and levulose has a specific rotatory power  $[\alpha]_D = 50^\circ$ . Complete inversion of raffinose takes some hours. Invertase also hydrolyses raffinose (O'Sullivan). The products of hydrolysis are at first levulose and melibiose (Scheibler a. Mittelmeier, *B.* 22, 8118), and melibiose is slowly acted on. When heated for some time with sulphuric acid, levulinic acid is a product (Rischbieth a. Tollens, *A.* 232, 195).

**Action of alkalis.** By boiling aqueous solutions of strontia and raffinose, di-strontia raffinose  $C_{18}H_{32}O_{16}(SrO)_2 \cdot H_2O$  is produced. Other compounds with baryta  $C_{18}H_{32}O_{16} \cdot BaO$ , lime  $C_{18}H_{32}O_{16} \cdot 3CaO \cdot 2H_2O$ , lead oxide  $C_{18}H_{32}O_{16} \cdot 3PbO$ , and soda,  $C_{18}H_{32}O_{16} \cdot Na_2O$  and  $C_{18}H_{32}O_{16} \cdot NaOH$ , have been prepared (Beythien a. Tollens, *B.* 22, 1047; *A.* 255, 195; Rischbieth a. Tollens, *A.* 232, 172).

**Oxidation.**—Nitric acid oxidises raffinose, producing 30 p.c. mucic acid, also saccharic and oxalic acids.

**Fermentation.**—Raffinose is slowly fermented by beer yeast (Rischbieth a. Tollens, *A.* 232, 242; Tollens, *A.* 232, 169; O'Sullivan, *C. J.* 1886, 73). Weak yeast only partially ferments it (Tollens, *l.c.*; Berthelot, *C. R.* 109, 548); the melibiose being with difficulty hydrolysed and fermented.

With phenylhydrazine a compound is formed, m.p. 187°–189° (Rischbieth a. Tollens, *l.c.*).

**Melaxitose**  $C_{18}H_{32}O_{16} \cdot 2H_2O$  is obtained from Persian manna, a product of *Alhagi maurorum* (DC.), it crystallises in rhombic prisms, m.p. 147–148° (when anhydrous); the specific rotatory power of the anhydrous body is  $[\alpha]_D = 87.7^\circ$ . On inversion it yields *turannose* and dextrose. Turannose  $C_{12}H_{22}O_{11}$   $[\alpha]_D = 65^\circ$ –68°, yields dextrose by the further action of acid (Alekhin, *J. R.* 21, 407).

(d) **Hexaheoses.**

**Gentianose**  $C_{18}H_{32}O_{16}$ . Obtained by A. Meyer (*H. B.* 136), from the root of *Gentiana lutea*, by extraction with alcohol, precipitation with ether and re-crystallisation from alcohol. It has a sweet taste, dissolves easily in water, m.p. 210°, does not reduce Fehling's solution, and ferments with yeast. It is hydrolysed by dilute acids; before inversion the optical activity is  $[\alpha]_D = 88.6^\circ$ ; after, it is 20.2°, and has a reducing power equal to that of dextrose. Strong sulphuric acid chars it, like cane sugar.

**Stachyose** is obtained from the root of *Stachys tuberosa*. It has a sweet taste, is dextrorotatory, having  $[\alpha]_D = 148.1^\circ$  in 9 p.c. solution. It forms triclinic crystals. When in-

verted it yields galactose, dextrose, and levulose. Its formula appears to be  $C_{24}H_{44}O_{22} + 6H_2O$  (Planta a. Schulze, *B.* 23, 1692; 24, 2705), the products of the hydrolysis being the same as those of raffinose.

**QUALITATIVE AND QUANTITATIVE DETERMINATION OF SUGARS.**

If the material to be examined is a solution, it must be made neutral, clear, and colourless if it is not already so.

If the material is a dry substance, it must be ground fine. If not sufficiently dry to admit of grinding, it must, if possible, be dried in vacuum over sulphuric acid, or, where this is not possible, in the open, at a low, gradually increasing temperature.

The finely-ground substance is extracted with alcohol sp. gr. 860–880. The solution is neutralised and the alcohol distilled off. The residue is taken up with water. The examination then comes under the head of a *solution*, and the treatment is the same.

**The solution is turbid and coloured after neutralisation.** The turbidity may be removed by simple filtration; if not, a little aluminium hydroxide (prepared by precipitating a solution of alum with excess of ammonia and washing free from ammonia and sulphuric acid) may be employed. A little (well washed) Swedish filter paper-pulp is at times found useful. The turbidity and colour may be removed together by animal charcoal, lead sulphide, barium sulphate, &c. Animal charcoal, either prepared from blood or bones, the former by preference, thoroughly extracted with hydrochloric acid and washed free therefrom, is best employed in all cases of investigation. The crude substances are employed to remove the colour, &c., from sugar syrups in the manufacture of refined cane sugar. These decolouring agents must always be used in the least possible quantity, and with the understanding that the charcoal especially is capable of taking up some sugar as well as colouring matter. Dried, freshly-made bone charcoal does not take up more than .006 p.c. of its own weight from pure cane-sugar solution (Casamajor, *C. N.* 41, 66). In quantitative work, when the decolourising agents have to be used it is well to have a knowledge of the influence of the agent on the sugar or sugars under examination. Charcoal retains sugar, other substances influence the optical activity. Part of the sugar is again given up on washing the agent with water, or the agent is placed on a filter and a portion of the solution to be examined passed through it and rejected before the portion intended for examination is collected. This is done on the supposition that the charcoal is sooner saturated with sugar than with colouring matter.

Having thus the sugars in clear solution, the means at our disposal for identification are:—

1. Taste of solution.
2. Form of crystals and melting-point thereof.
3. Depression of the freezing-point (Raoult's method of determining molecular weights).
4. Specific rotatory power.
5. Reducing power.
6. Action of unorganised ferments: enzymes.
7. Action of organised ferments.

## 8. Action of acids.

## 9. Action of alkalis.

## 10. Action of phenylhydrazine, and melting-points of the resulting osazones and hydrazides.

1. The solution tastes sweet if a sugar is present. It must not be forgotten, however, that some other bodies are also more or less sweet.

2. On evaporating this solution (best in a vacuum) to a syrup, if there is no preventive material present, crystallisation takes place. The microscopic appearance of the crystals will often be sufficient to identify the sugar; indeed, the habit of crystallisation will often suffice. A substance or substances may be present which altogether prevent the crystallisation of the syrup, although it may contain a crystallisable sugar. This substance may be an inorganic or organic salt, or another body, or, indeed, another sugar. Treatment with strong or absolute ethylic or methylic alcohols may at times eliminate some or the whole of the substances preventing the crystallisation, and dissolve the sugar in so clean a state as to admit of the formation of crystals on concentration.

3. *Depression of the freezing-point* (Raoult's method). For references to Raoult's work see Victor Meyer, *B.* 21, 536; Auwers, *id.* 701; Tollens a. Meyer, *id.* 1566; and Brown a. Morris, *C. J.* 1888, 610. When crystals are obtainable from the solution as described above, a determination of the molecular weight by this method will decide to which group it belongs: a hexose or a pentose, a dihexose or dipentose, a trihexose. In the recorded observations water of crystallisation appears not to have received proper attention. Tollens a. Meyer record observations for dextrose  $C_6H_{12}O_6$ , so do Brown a. Morris. Water of crystallisation is not taken into account; the former treat of  $C_{12}H_{22}O_{11} \cdot H_2O$  for lactose, the latter omit the  $H_2O$ , while both employ crystallised raffinose  $C_{18}H_{32}O_{16} \cdot 5H_2O$ , mol. = 594, with the result that T. a. M. find the observed molecular weight between 544 and 644, and B. a. M. between 518 and 533. In these experiments with raffinose and lactose, it is not possible to say whether it is intended that the crystallisation water functions with the solid sugar or with the water; the calculations make it function with the sugar, but the results, as might have been expected, are unsatisfactory—it does not function with the sugar. It is perfectly clear that water of crystallisation of a sugar must be looked upon as water in observations with this method—that the quantity of dry sugar should be the factor dealt with. If the crystals contain water of crystallisation it should be determined and allowed for. A determination of the D will give some information as to whether a dry sugar or one containing water of crystallisation is being dealt with. The D of the different sugars in the dry state is given under each sugar. Between 8 and 15 g. dry substance is dissolved in water and the solution made up to 100 c.c. at 15.5°. A determination of the specific gravity of this will give a means of calculating the D, and the number of g. of water to substance employed in the solution. About 60 c.c. of this solution are introduced into a thin glass (120 c.c.) beaker. The

mouth of the beaker is loosely closed with an indiarubber plug, in which three holes are bored. One of these, in the middle, admits of the introduction of a thermometer; the second, at the side, carries a stirrer, of very thin glass rod or platinum, best in the form of a flat coil, so that when the stirrer is moved up and down in the liquid the thermometer will be in the middle of the coil; and the third, also at the side, to admit of the introduction of a small solid particle of the frozen solution or of ice. The thermometer must be graduated for 2° or 3° above and below 0° to the 20th of a degree. By means of a telescope, if the divisions are open, and they should be so, readings to .005° can be made with a fair amount of accuracy. The beaker thus charged and fitted is placed in a freezing mixture of ice and salt—which should not be at too low a temperature, —4° to —5°, not more than 2°–3° below the freezing-point of the solution—contained in a strong beaker of 500–600 c.c. capacity. In a short time the temperature in the inner beaker will be observed to sink below 0°, and, on rapidly moving the stirring rod up and down, to go gradually lower and lower until a point is reached when the solution begins to freeze. This may be accelerated by adding a particle of the solution previously frozen; when freezing begins the mercury of the thermometer rapidly rises and soon becomes stationary. This is the freezing-point of the solution *c*, and is the observation upon which the molecular weight of the substance employed is calculated.

$$M = \frac{19}{A}, \quad A = \frac{c \times y}{x \times 100}$$

$x$  = g. substance;  $y$  = g. water, and 19 is a number calculated by Raoult for water as a solvent from observations with well-defined compounds. As examples, Brown a. Morris (*loc. cit.*) with a solution containing 8.258 g. sucrose and 94.93 g. water observed a freezing-point  $c = 0.490^\circ$ , thence

$$M = \frac{19}{.49 \times 94.93} = 337.5, \quad C_{12}H_{22}O_{11} = 342.$$

Hence, if an unknown sugar were under observation there would be no doubt left as to the molecular weight. O'Sullivan (*C. J.* 1890, 59) observed for arabinon: sp.gr. sol. 1.02554,  $y = 96.088$  g.,  $x = 6.466$  g.,  $c = 0.535^\circ$ ; thence

$$19 + \frac{96.088 \times .535}{6.466 \times 100} = 239.2,$$

the molecular weight of the new sugar. A dipentose requires 282. The indications agreed with further confirmatory observations. When the solution contains more than 12 g. per 100 c.c. the results are low; with most sugars a solution containing from 5 to 8 g. substance per 100 c.c. gives the best results, and with more dilute solutions the results are again low. Raoult's latest observations (*C. R.* 114, 264) for sucrose, made with apparatus constructed to meet the exact requirements of the case, the concentration of the solution being 5.839 g. sucrose in 100 g. water, work out  $M = 323$ , against 342, the true molecular weight. The results are, even under the best conditions, low; but the indication is sufficiently good to enable us to decide to which group the sugar we are dealing with belongs. If, instead of the factor 19, 19.8 were substituted, the results would agree with the accepted molecular

weight of sucrose, and it is probable that this number or 20 will be finally decided upon as the constant.

4. *Specific rotatory power.* If the form of the crystals or their habitat does not indicate the sugar present, a determination of the specific rotatory power may give the desired information. This is the quantitative expression of a property possessed by the sugars in common with many other substances. When light from any source is examined through a Nicol prism—i.e. polarised—no change is evident; but if the light, after passing through one prism (the *polariser*) is examined by another, it is found that in certain positions of the examining prism—or *analyser*, as it is called—no light passes. If the analyser is made to carry an index, and is so mounted as to rotate with its axis at right angles to a disc graduated to degrees, it will be found that, if the position of the two prisms is so arranged that the index is at  $0^\circ$  on the graduated circle when no light passes, light will pass on the least rotation of the analyser to the right or left, and if the movement is continued another position is found on the disc in which the light is again cut off. This is at  $180^\circ$ , so that the circle should be graduated to  $180^\circ$  right and  $180^\circ$  left. Now, if a cell or tube with flat glass caps be filled with a solution of, say, sucrose and introduced between the two Nicols, and the source of light be a Bunsen burner flame coloured yellow with sodium chloride, when the index of the analyser is at  $0^\circ$  it will be observed that the light passes, and that on rotating the analyser a certain number of degrees to the right a point is found (which is not  $180^\circ$ ) at which the light is cut off; and if note be taken of the exact number of degrees, and the analyser rotated further, it is found that the light is not again cut off at  $180^\circ$ , but the same number of degrees beyond  $180^\circ$  as the first extinction was beyond  $0^\circ$ . This is the *optical activity* of the sugar solution. It is the power of rotating the plane of polarisation of the ray passing through the polariser so as to admit of its passing through the analyser when it would not pass had the sugar solution not been introduced. The amount of rotation of the analyser to again find the direction of the plane of polarisation, as indicated by the index on the graduated disc, is the measure of the activity of the sugar solution, and the direction of the movement of the index is the direction in which the rotation has taken place; in the present case (i.e. when the index is moved on the disc in the direction of the hands of a watch) *right* or *+*. If the sugar solution be now hydrolysed by dilute acids or invertase, and again introduced between the Nicols, it is found that the analyser must be rotated to the left in order to find the position of extinction—i.e. the direction of the plane of polarisation of the rotated ray. This is *left* rotation, and is indicated by the sign *-*. On further rotation of the analyser light again passes, and finally there is a second extinction as far beyond  $180^\circ$  as the first extinction was beyond  $0^\circ$ . From this it is clear that the second reading may indicate right-handed rotation as well as left. Say the first extinction was  $10^\circ$  left of  $0^\circ$  ( $-10^\circ$ ), the second would be  $+170^\circ$ ,  $10^\circ$  less than  $180^\circ$ ; then the activity might be

$-10^\circ$  or  $+170^\circ$ . On diluting the solution say one-half, if the activity is  $-$  the readings will be  $-5^\circ$  and  $+175^\circ$ ; if  $+$  they will be  $+85^\circ$  and  $-95^\circ$ . The exact measurement of this activity has been the subject of much investigation, and many plans have been devised to facilitate the operation. It is, however, beyond the scope of this article to deal more fully with the subject (for details see *Das optische Drehungsvermögen organischer Substanzen*, Landolt, Braunschweig, 1879, *Engl. Trans.*; *Handbook of the Polariscopes*, Macmillan & Co., 1882; *Watts' Dictionary*, Suppl. 3, art. LXXXI). In the experiments above described the light of a sodium flame was employed; it was observed early in the investigation of the phenomena that readings sufficiently accurate, especially if the amount of activity was small, could not be obtained. Hence other devices were introduced. In the literature we find the activity expressed  $[\alpha]_D$ ,  $[\alpha]_L$ , or  $[\alpha]_D$ , and  $[\alpha]_D$ ,  $[\alpha]_L$ , &c.

$[\alpha]_D$  values are not now used. They were obtained by employing white light, and interposing between the polariser and the source of light a plate of red glass. They are of no value for our purpose, and may be neglected.

$[\alpha]_D$  values are frequently used, but unless they are referred to a definite standard they, too, are of no value. If any ordinary source of white light be substituted for the sodium flame in the experiments above described, it will be observed that on rotating the analyser to find the effect produced by the sucrose solution no position of the analyser can be found in which all the light is cut off, but at one stage marked blue light passes, and, on further rotation of the analyser, red. This is due to the fact that the sugar solution acts unequally on the different rays of which the beam of white light is composed, the red rays being rotated least and the violet most, so that when the analyser is rotated the ray the plane of polarisation of which is rotated least is first cut off. The first cut off rays are the red, the complement of those cut off passing, the dominant being blue; on further rotation the dominant becomes red. On rotating the analyser carefully it is found that the *transition* from the blue to the red is well marked; this is the  $\alpha_1$  value; it is the, so-called, *transition tint*, the ray complementary to the median yellow, *jaune moyen*; hence  $\alpha_1$ . For the same strength of sugar solution the position of the analyser is not the same for every source of white light. The stage at which the transition appears with candle-light is different from that at which it appears with gas-light; the stage in this case differs again from that obtained with the electric light, and even the position for direct sunlight differs from that of the light reflected from a cloud. Hence, when a pair of Nicols are employed as described above, even when the source of light is given,  $\alpha_1$  cannot be looked upon as a standard value. This value has, however, been given to it by the French instrument makers.

Soleil invented an instrument with which lamp- or gas- light is employed (afterwards improved by Duboscq, and known as the *Soleil-Duboscq* (see *Watts' Dictionary*, 1st ed. 3, 674, a. Suppl. 8, 1199), by which the activity of a solution is measured by *divisions* of a scale instead of degrees; 100 of these divisions were

made equal to the amount of rotation produced by 1 mm. quartz for the  $\alpha_1$ ; this was considered to be  $24^\circ$ . Of course, if this is taken as a standard it is of full value; it may not be truly  $\alpha_1$  even for the quartz, but it is  $\alpha_1$  referred to a definite measure, the 100 divisions of the instrument being  $24^\circ$ . This was complicated by the fact, since pointed out by Scheibler, that quartz from different sources has not the same optical activity; hence we have various observers giving different values for the amount of sucrose in 100 c.c. solution, which when observed with the Soleil-Duboseq instrument, in a tube 200 mm. long, equals the activity of 1 mm. quartz. If, however, we look upon the 100 divisions of the instrument as  $-24^\circ \alpha_1$ , we have a standard value for the expression. I believe this is the value given to it by the French observers. The writer employed it in the same way. Another instrument of much the same construction is the Soleil-Ventzke-Scheibler (v. Watts, L.c.). In this the 100 divisions of the scale are made to represent the activity of 26.048 g. saccharon in 100 c.c. solution; we have only to inquire as to the  $[\alpha]_D$  and  $[\alpha]_D$  of cane sugar to arrive at a value in degrees of the 100 divisions for these two expressions. From these two factors we get 100 divisions, Soleil-Duboseq  $= 24^\circ \alpha_1$  and  $21.67^\circ \alpha_D$ , and 100 divs. S.V.S.  $= 38.34^\circ \alpha_1$  and  $34.55^\circ \alpha_D$ . The angular value for any other instrument in use in which the scale is given in divisions can be calculated for  $\alpha_1$  or  $\alpha_D$  by ascertaining the number of divisions required to compensate a solution of sucrose containing 10 g. in 100 c.c. at  $15.5^\circ$ , and taking the apparent specific rotatory power of the sugar for the concentration to be  $[\alpha]_1 = +73.8^\circ$  and  $[\alpha]_D = 66.6^\circ$ , the value of the divisions in degrees for both rays can be calculated. The direction of the rotation is indicated in these instruments by the direction of the movement of the 0 point to find the compensation necessary; if from left to right it is right or +, if in a contrary direction left or -. With the other instruments in use sodium flame is the source of light employed; the readings are therefore  $\alpha_n$ . The scale is a circle graduated to degrees on a disc, beginning with 0 at the top and graduated in half degrees and degrees to  $180^\circ$  to the right, and in the same way to the left. The analyser rotates in the axis of this disc, and carries an index with vernier, which admits of readings being made to minutes. The arrangement is such that the polarised ray before entering the active solution has the appearance of a circular disc divided into halves by a perpendicular diameter. The position of the plane of polarisation is not the same in both semi-discs, so that when the light is completely cut off at one side it passes at the other, and vice versa. To find these positions the analyser has to be rotated several degrees, but between the two positions of complete cut off there is a position of the analyser in which the two semi-discs are equally illuminated; this is a well-marked position distinctly ascertainable. The 0 point of the index and of the graduated scale are made to correspond exactly with it. It can always be found to within less than a minute. When the active substance is introduced the equality of the illumination of the semi-discs is

VOL. IV.

destroyed; the analyser is rotated until it is again restored. The amount of rotation as shown by the graduations gives the activity in degrees and minutes, of degrees and decimals, according to the make of the vernier. These are the half-shadow instruments, of which the Jellet-Cornu and Laurent are examples (see Watts, L.c.). Other devices have been employed to facilitate an accurate determination of the position of the plane of polarisation of the ray before and after rotation; a description will be found in Landolt and in Watts (L.c.). Recently an instrument has been introduced in which the half-shadow contrivance is adopted, white light (a strong gas-flame) being employed. The scale is the same as that of the Soleil-Ventzke-Scheibler instrument; readings with it can be made with great accuracy. It is manufactured by Schmidt & Haensch, Berlin.

When it is necessary to determine the activity for rays of other refrangibility, say for the lithium or the thallium flame, it is only necessary to colour the Bunsen flame with these metals in the same way as in the case of sodium above. The readings are then  $\alpha_L$  and  $\alpha_n$ . The  $\alpha_n$ ,  $\alpha_o$ ,  $\alpha_p$ , &c. for any active substance can be found by employing a pair of ordinary Nicols as described above—white light, best a ray of sunlight, being employed—and examining the light after passing the analyser, with a spectroscope. If the positions of the lines of the solar spectrum are marked, the amount of rotation for the active substance introduced between the polariser and the analyser is found, when on rotating the analyser the thickest part of the black band is on the marked position of the line of the spectrum. This is read off on the scale connected with the analyser.

With any of these instruments we can determine the optical activity of a sugar and thus identify it. The sugar is crystallised; it is dried, and 10 g. or thereabouts carefully weighed out. This is dissolved in water, and the solution made up to 100 c.c.<sup>1</sup> at  $15.5^\circ$ . A portion of this is introduced into a tube of definite length, and an observation made with any of the instruments mentioned above. The formula  $[\alpha] = \frac{c \cdot l}{l}$  gives the apparent specific rotatory power for the concentration.  $\alpha$  = the angular disturbance observed,  $l$  = length in decimetres of tube employed, and  $c$  = grams substances in 100 c.c. Let us take an example, 10 g. sucrose, dissolved and made up to 100 c.c. Disturbance observed in a 200 mm. tube with a Soleil-Duboseq instrument,  $= 61.5$  divs.; now for  $\alpha_1$  100 div.  $= 24^\circ$ . Then, substituting the values in the above formula we have

$$\frac{61.5 \times 24 \times 100}{2 \times 10} = [\alpha]_1 = +73.8^\circ$$

100 divs.  $= 21.67^\circ \alpha_D$ ; then

$$\frac{61.5 \times 21.67 \times 100}{2 \times 10} = [\alpha]_D = +66.6^\circ.$$

The scale of the Soleil-Ventzke-Scheibler instrument is so graduated that 100 divisions = the activity of a solution of sucrose containing

<sup>1</sup> This is practically the usual 100 c.c. of a volumetric analysis. For more accurate manipulation see Landolt. This is, however, unnecessary for the identification of the sugar—our purpose.

26.048 g. in 100 c.c. in a 200 mm. tube. The apparent specific rotatory power of sucrose in a solution of this concentration is  $[\alpha]_D = 66.33^\circ$  and  $[\alpha]_B = 73.61^\circ$ . Substituting these values in the formula we get

$$\frac{\alpha \cdot 100}{2 \times 26.048} = 66.33;$$

$\alpha$  = the value of 100 divisions in degrees  $\alpha_D$  =  $34.55^\circ$ , and

$$\frac{\alpha' \cdot 100}{2 \times 26.048} = 73.61;$$

$\alpha'$  = the value of 100 divisions  $\alpha_B$  =  $88.34^\circ$ .

It is of importance that the values in degrees of the scales of these two instruments should be clearly understood. We find it stated that a quantity of sugar varying from 16.49 to 16.35 g. in 100 c.c. require, in a 200 mm. tube, a compensation with a Soleil-Duboscq instrument = 100 divisions; 16.35 g. is the best-recognised factor; from my observations it is still too high.

$$\frac{100 \times 24 \times 100}{2 \times 16.35} = [\alpha]_B = 73.39^\circ, \text{ and}$$

$$\frac{100 \times 2167 \times 100}{2 \times 16.35} = [\alpha]_D = 66.27^\circ,$$

figures slightly too low for the apparent specific rotatory power of sucrose for the  $c$ , hence 16.35 g. is too high. The number, no doubt, should be 16.28, and this gives factors agreeing well with the observed  $[\alpha]_D$  and  $[\alpha]_B$  for the  $c$ .

A solution containing 10 g. sucrose in 100 c.c. requires a compensation in a 200 mm. tube of 38.5 divisions if a Soleil-Ventzke-Scheibler instrument.

$$\frac{38.5 \times 3834 \times 100}{2 \times 10} = [\alpha]_B = 73.8^\circ \text{ and}$$

$$\frac{38.5 \times 3455 \times 100}{2 \times 10} = [\alpha]_D = 66.5^\circ,$$

numbers agreeing accurately with the specific rotatory power for the  $c$ . The optical arrangements of these instruments admit of the employment of white light.

If either of the sodium-flame instruments is employed the angular disturbance is introduced directly into the formula. With the 10 g. in 100 c.c. solution of sucrose, the reading in a 200 mm. tube is

$$\alpha_D = +13.8^\circ, \text{ then } \frac{13.3 \times 100}{2 \times 10} = [\alpha]_D = 66.5^\circ. \text{ The}$$

use of this factor is obvious. We have a solution of a known sugar of unknown strength, and want to find the  $c$  (g. in 100 c.c.). An observation is made in a tube of known length,

$\alpha_D$  or  $\alpha_B$ ; then  $\frac{\alpha \cdot 100}{l \cdot c}$  = the determined value of  $[\alpha]_D$  or  $[\alpha]_B$ ,  $\alpha$  the ray for which the observation is made, and  $[\alpha]$  the specific rotatory power for that ray, according to the light employed and concentration,  $c = \frac{\alpha \cdot 100}{[\alpha] l}$ .

It has been shown that if a solution contains two or more active substances, the observed activity is the algebraic sum of the activities of the constituents. The specific rotatory power of each individual sugar is given in the description of it.

5. The reducing power. As has been stated, most of the sugars possess the power of redu-

cing the oxides of the higher metals and some organic colouring matters. Various propositions have been made to employ this property as a means of qualitatively and quantitatively determining the sugars, and various solutions have been proposed for that purpose; but speaking with many years' experience I may say that they may all be discarded in favour of alkaline copper solution, *Fehling's solution*; and even with regard to the value of this a great diversity of opinion exists. But there is a general agreement that if the conditions under which it is used are constant the results are constant. For literature see Becquerel, *A. Ch.* [2] 47, 15; Trömmner, *A.* 38, 360; Müller a. Hagen, *F.* 23, 221; Neubauer, *Fr.* 1, 878; Maly, *Fr.* 10, 383; Seegen, *C. C.* 1875, 223; Fehling, *A.* 72, 106; Claus, *J. pr.* [2] 4, 63; Neubauer, *Ar. Ph.* [2] 71, 278; Patterson, *C. N.* 25, 149; Loiseau, *C. R.* 1873, 26; Soxhlet, *J. pr.* [2] 21, 227; Krause a. Städeler, *C. C.* 1854, 936; Gräber, *Fr.* 7, 490; Buswitz, *B.* 11, 1445; O'Sullivan, *C. J.* 1876, 2, 125; Mäcker, *O.* 7, 699; Brunner, *Fr.* 11, 32; Bayley, *C. N.* 37, 211; Allihn, *J. pr.* [2] 22, 55; Salomon, *B.* 14, 2711; Digener, *Z. V.* 31, 349; Schwarz, *A.* 84, 84; Mohr, *Fr.* 12, 296; Perrot, *B.* 9, 19; Ulbricht, *B.* 10, 128; Jean, *C. R.* 73, 1397; Scheibler, *Z.* 9, 820; Weil, *Fr.* 11, 234; Arnold, *Fr.* 20, 331; Volhard, *A.* 190, 1; Soldaini, *B.* 9, 1126; Possos, *C. R.* 1874, 721; Pellet, *J. Fab.* 19, 22; Pavy, *C. N.* 39, 1004; Löwe, *Fr.* 9, 20; Vogel, *J. Ph.* [2] 1, 245; and others of less value. As a result of a study of all this literature, I may say that I have come to the conclusion that if the Fehling's solution is carefully made with pure materials, and employed as described below, the reducing power of any sugar can be determined with constancy and accuracy, and when the conditions are fulfilled the reduction is molecular—i.e. a definite number of copper oxide molecules are reduced by a definite number of molecules of the sugar.

Fehling's solution is made as follows: 34.61 g. pure recrystallised copper sulphate are dissolved in 400 c.c.  $H_2O$  or thoreabouts, 173 g. sodium potassium tartrate (Rochelle salt), and 74 g. freshly-prepared sodium hydroxide (commercial stick soda) are dissolved to 450  $H_2O$ ; when the solution is cold it is gradually added to the copper solution in small portions at a time, so that the pp. at first formed is re-dissolved. When both solutions are mixed the volume is made up to 1 litre. It is very generally stated that this solution does not keep very well. I found it constant in its properties for more than twelve months when kept in carefully-stoppered bottles, sealed with paraffin in a cool, dark place. Some recommend that both the solutions be made up to 500 c.c., kept separately and mixed in equal volumes when required for use. This is probably the better plan but unless the solutions are kept in well-stoppered bottles sealed they will deteriorate as badly as if mixed. This solution is used as a qualitative test for the reducing sugars. I

<sup>1</sup> O. = Organ des Centralvereins für Rübensuckerfabriken (in der österreichisch-ungarischen Monarchie).

<sup>2</sup> Journal des Fabricants de Sucre.

<sup>3</sup> Redewald a. Tollens (*B.* 11, 2078) employ 60 g. and they say the increase of alkali to 70 g. diminishes the reducing power of lactose about 1 p.c.

is also used (b) quantitatively, to determine the reducing power and the quantity of a sugar.

(a) *Qualitatively.* A portion of the solution supposed to contain sugar, prepared as described, is heated to boiling in a small beaker or test-tube, and is added to 5 c.c. of the alkaline copper solution previously diluted with its own bulk of water, and heated to boiling. The production of a red pp. of  $\text{Cu}_2\text{O}$  indicates the presence of a reducing sugar. There are substances besides the sugars capable of reducing Fehling's solution. The absence of these must be established before it can be inferred that the reduction is due to sugar.

(b) *Quantitatively.* The reducing power of a sugar, or of a solution containing reducing sugars, can be determined volumetrically or gravimetrically, with Fehling's solution. It is now very generally admitted that the gravimetric method gives the only reliable results.

*Volumetrically.* The sugar solution, prepared as described, should be diluted (0.5 to 1.0 g. reducing sugar in 100 c.c.). This is introduced into a burette, and the Fehling's solution into a second one. Of the latter a definite quantity, say 10 c.c., is measured into a porcelain dish of about 60 to 100 c.c. capacity, and diluted with four times its own bulk of water. The dish is then placed over a small Bunsen, and the contents heated to boiling. The sugar solution is then run in a c.c. at a time until the blue colour of the copper solution has nearly all disappeared, then drop by drop until it has quite gone. The first experiment may only give approximate results; in a second a quantity of sugar slightly less than was found necessary in the first experiment is measured into a small beaker, heated to boiling, and mixed rapidly with the boiling dilute copper solution. If the whole of the copper is reduced, a few drops more of the Fehling's solution are added from the burette. A few experiments of this kind will give fairly approximately the amount of copper solution a certain quantity of the sugar solution is capable of reducing. That the Fehling's solution is not in excess is seen by the absence of blue on subsidence of the  $\text{Cu}_2\text{O}$ , and may be confirmed by filtering a little and testing for copper with a dilute solution of potassium ferrocyanide in acetic acid. The absence of a brown colouration indicates the absence of  $\text{CuO}$ . If the sugar is in excess, more  $\text{CuO}$  solution is decolourised, but after boiling the sugar in the alkaline solution the amount reduced is not a measure of the quantity of sugar. The final experiment must be performed after two or more observations, when the relative value of the two solutions has been approximately ascertained, as described above, by adding the whole, or nearly the whole, of the sugar at a boiling temperature to the copper solution at once. If only a few drops of the sugar solution are required to remove the last traces of  $\text{CuO}$ , the error is not great; 10 c.c. of the Fehling's solution, made as directed, contain 1100 g.  $\text{CuO}$ ; 896  $\text{CuO} = 180$  dextrose, i.e. 5 mols.  $\text{CuO}$  ( $79.2 + 5 = 896$ ) are reduced by 1 mol. dextrose 180, then  $896:110 = 180:0.50$  grams dextrose = 10 c.c. Fehling's solution. Soxhlet (l.c.) states that the value of the  $\text{CuO}$  solution in dextrose varies with the way in which the experiment is performed; that 10 c.c. undiluted Fehling's solution are reduced by

0.04753 g. dextrose, while it takes 0.0494 to reduce the same bulk diluted with four measures of water. The same applies to the other reducing sugars, only in the case of lactose dilution has no effect, while in that of maltose dilution diminishes the amount of sugar required. This is, no doubt, correct under the conditions stated, but it is not necessary in dealing with a reaction of this kind to deviate from recognised conditions such as those laid down above. When these are adhered to it is found that the reducing power of the sugar very closely approaches molecular interaction; in fact, so much so that the molecular relation most closely approximated to by the experimental data may be taken as the normal reducing power of a sugar. These normals for the better-known sugars are:—

10 c.c. Fehling's solution =	0.0500 g. dextrose.*
" "	0.0500 g. galactose.
" "	0.0500 g. levulose.
" "	0.06334 g. lactose.†
" "	0.07196 g. maltose.†
" "	0.04630 g. arabinose.
" "	0.08701 g. arabinose.

\* Soxhlet says the reducing power of levulose is different from that of dextrose. This is not supported; his error is due to his mode of preparing invert sugar.

† Sugar free from water of crystallisation.

*Gravimetrically.* The Fehling's solution is prepared as described; 25.30 c.c. of it are measured into a beaker of 130-140 c.c. capacity, and about 50 c.c. well boiled water added. The beaker is then placed in a boiling-water bath, consisting of a larger beaker in which water is kept boiling. At the end of five or six minutes, when the dilute copper solution has acquired the temperature of the bath, a known weight or measure of the sugar solution is heated to boiling, and added. If at the end of a few minutes the blue colour is completely destroyed, it can be restored by adding more Fehling's solution, but it is much better to so arrange matters by a few experiments that the amount of sugar solution employed will reduce the Fehling's as nearly as possible, leaving only sufficient blue, on subsidence of the  $\text{Cu}_2\text{O}$ , to make it evident that the copper solution is in slight excess. After twelve or fourteen minutes' boiling the clear supernatant liquid is decanted on to a filter, the  $\text{Cu}_2\text{O}$  is washed by decantation, and finally on the filter. If the Fehling's solution is in large excess it is difficult to wash the filter free from unreduced copper oxide (blue colouration); but if the excess is only slight there is no indication that the filter retains copper compounds other than  $\text{Cu}_2\text{O}$ . Ignition for four or five minutes in an open porcelain crucible converts the red precipitate into black copper oxide  $\text{CuO}$ , in which form it is weighed. From this the sugar is calculated by multiplying by the constants (see next page). It may be again pointed out that the factors given by various authorities differ more or less from these (see the K of individual sugars), but I believe these are the constants, the differences amongst the authors being due to manipulation, to the state of dilution and alkalinity of the solutions, and to the temperature of the mixed sugar and  $\text{CuO}$  solution. An imperfect knowledge of the composition of the material is a source of error. In dealing with some solutions, other

1 mol. sugar to 5 mols. CuO :	1 g. CuO = 0.4545 g. dextrose	: K = 100
" " 5 " " 1 g. "	= 0.4545 g. galactose	: K = 100
" " 5 " " 1 g. "	= 0.4545 g. levulose	: K = 100
" " 7.5 " " 1 g. "	= 0.5758 g. lactose	: K = 77.67
" " 6 " " 1 g. "	= 0.7196 g. maltose	: K = 68.16
" " 4.5 " " 1 g. "	= 0.4209 g. arabinose	: K = 108.8
" " 4.5 " " 1 g. "	= 0.7910 g. arabinon	: K = 67.5

substances may be precipitated with the  $\text{Cu}_2\text{O}$ . These should be ascertained, determined, and allowed for. In dealing with solutions in which ammonia is found, or liberated by the alkali,  $\text{Cu}_2\text{O}$  is retained in solution. Sundry propositions have been made to avoid the disturbing influence of the alkali in Fehling's solution, but they seem to have met with no favour. Soldani (*B. 3*, 1126) proposed copper carbonate in potassium bicarbonate; Possoz (*C. R.* 1874, 721) and Pellet (*J. B.* 19, 22) other solutions of copper in alkaline carbonates. Löwe (*Fr.* 9, 20) recommends the use of a solution of  $\text{CuO}$  in glycerol, but so far little can be said of the value of the solution. In cases where the sugar solution contains other substances than reducing sugars capable of giving a precipitate with Fehling's solution without reduction, the whole precipitate may be dissolved in hydrochloric acid, made strongly alkaline, and added to an excess of ammoniacal solution of silver nitrate. The copper suboxide reduces an equivalent quantity of silver oxide. The silver in the precipitate may be estimated as chloride (Jean, *C. R.* 73, 1397). As has been stated above, many other solutions and modifications of Fehling's solution, have been proposed for employment in determining the sugars, but they appear to be of no value.

Pavy (*L.c.*) recommends the addition of sufficient ammonia to the Fehling's solution to hold the  $\text{Cu}_2\text{O}$  in solution; the disappearance of the blue is then the indicator of the reaction. The reducing powers for sugars other than dextrose for this solution have not been ascertained; even for dextrose it is doubtful (*v. Hefner, An.* 6, 218).

Three solutions of mercury salts have been proposed as agents by which sugars can be determined by their reducing power—the one known as Knapp's solution, the other as Sachsse's solution, and the third as Hager's solution. Neither of them are of high value, except in certain circumstances, but Hager's least of all.

Knapp's solution is made by dissolving 10 g.  $\text{HgCy}_2$  in about 600 c.c. water, then adding gradually 100 c.c. sodium hydroxide solution, specific gravity 1.145, and diluting the clear solution to 1 litre; 10 c.c. of this solution equal 0.025 g. dextrose; but according to Soxhlet (*L.c.*) this is not true, and the quantity varies with the conditions under which the reducing solution and reducible one are brought in contact, and even with the indicator used in determining the absence of mercury. The solution is used as follows:—40 c.c. of it are heated to boiling in a flask, and the sugar solution, which should not contain more than 0.5 p.c. reducing sugar calculated as dextrose, run in as quickly as possible until the whole of the mercury is p.p.d. as such, the mixed liquids being kept continually boiling. The complete precipitation of the Hg is ascertained by testing for

it with ammonium sulphide, or alkaline tin solution. Less mercury is reduced by adding the sugar gradually than when the addition is made all at one time (Brunner, *J. pr.* [2] 21; Soxhlet, *L.c.*). According to the latter, when the reducing solution is added all at one time, and alkaline tin solution employed as a test for the absence of Hg from the solution, 0.200–0.202 g. dextrose reduce 100 c.c. of Knapp's solution.

Sachsse's solution is made to contain in 1 litre 18 g. mercuric iodide, 25 g. potassium iodide, and 80 g. potassium hydroxide. The mercury salt is dissolved in a solution of the potassium iodide, the solution of the potassium hydroxide added, and the mixture made up to the litre. A measured quantity, 40 c.c., of the solution is boiled in a porcelain dish, and the sugar solution, containing not more than 0.5 g. per 100 c.c., run in until a drop of the supernatant liquid ceases to give a brown colour with an alkaline solution of tin chloride. It is said that in using this reagent more mercury is reduced by adding the sugar slowly than by adding it all at one time, the reverse being the case with Knapp's solution. Soxhlet (*L.c.*) compares the value of these solutions for the reducing sugars as follows:—

Taking the reducing power of dextrose = 100, the reducing powers (K) of the other sugars are:

	Fehling (undiluted)	Knapp	Sachsse
Dextrose . . .	100	100	100
Invert sugar . .	96.2	99	124.5
Levulose . . .	92.4	102.2	148.6
Galactose . . .	93.2	83.0	74.8
Lactose (hydrated?)	70.3	64.9	70.9
Maltose (dry?) .	61.0	63.8	65.0

These relations for the K of the sugars for Fehling's solution do not agree at all with the generally recorded numbers (*v. K.* of individual sugars); there are no data to enable one to form an opinion on the value of the K for the other solutions.

Potassium ferricyanide has been proposed as an agent for determining the reducing power of the sugars by Gentile (*Fr.* 9, 453), but although Stahlschmidt (*B.* 1, 141), Stammer (*D. P. J.* 158, 40), and Sostmann (*V. Z.* 22, 170) have worked with it, we know nothing very definite about its value. It should yield definite results, as the complete reduction is definitely recognisable.

6. The action of unorganised ferments. *Enzymes.* Sucrose is converted by invertase into levulose and dextrose; the only other sugar acted upon by this enzyme is raffinose (Kjeldahl, *Fr.* 22, 588; O'Sullivan, *C. J.* 1886, 70; and O'Sullivan & Thompson, *C. J.* 1890, 894), and, as it has been shown, the invertive action is most active at a temperature at which yeast, from which the invertase is prepared, has no fermentative action on the products of the inversion; yeast can be employed instead of prepared invertase. The products of the action of invertase

on raffinose are levulose and melibiose, the latter yielding finally dextrose and galactose. Raffinose is but very sparsely distributed. It may be considered that sucrose is present if the optical activity of a solution is materially altered by treatment with invertase and the copper oxide reducing power at the same time increased. The absence of raffinose can be determined by the non-production of mucic acid on treatment with nitric acid. Before applying the invertase test the solution to be tested must be boiled. If this is not done, and active diastase and any of the high-starch transformation products are present, the latter would be acted upon by the diastase, the opticity lowered, and the cupric reducing power increased. Diastase does not appear to act on any of the sugars, except isomaltose (?).

Other organisms, such as the moulds which grow on steamed rice, contain an enzyme capable of acting on maltose, but this substance has not been employed in the detection or estimation of maltose. There is no doubt, however, it is available for the purpose.

7. *Organised Ferments* (see FERMENTATION). The *hyphomycetes*, *saccharomycetes*, and *schizomycetes* act on the sugars and yield various products, and, no doubt, can be made available for the detection and estimation of them; but we have only to concern ourselves here with the action of ordinary beer yeast (*saccharomyces cerevisiae*); the changes effected by the other organisms come under art. FERMENTATION. On adding pressed yeast to a very slightly acid solution, and keeping the mixture at a temperature of 20° or thereabouts, if a fermentable sugar be present, a frothy head will form on the surface of the liquid, carbon dioxide will be evolved, and alcohol formed. The specific gravity and optical activity of the solution diminishes. Certain substances known as antiseptics prevent this reaction—they must be proved to be absent. The fermentable sugars, in this sense, are described as such under the respective heads.

The quantitative value of this phenomenon has been studied by many workers, but it is still unsatisfactory. It has been made available with approximate accuracy in determining the total fermentable sugars in presence of other substances from which they cannot otherwise be conveniently separated. The solution should be of about sp.gr. 1.050–1.060, slightly acid, and should not contain much foreign matter. A measured quantity of this is taken, best 100 c.c. if available, introduced into a 150 c.c. flask, and 0.5 to 1 g. freshly-pressed yeast added. If necessary, a little yeast ash dissolved in the least possible quantity of hydrochloric acid, together with a little ammonium tartrate, should be added. A temperature of from 20° to 22° is best suited for the process. The gas evolved is washed by being made to pass through a few c.c. water in two successive wash-bottles. In some cases the fermentation is very slow and takes many days to complete itself, in others it is rapid and is finished in a few days; but in all cases it should be continued as long as gas bubbles through the wash-bottles on shaking the flask in which the fermentation is going on. As soon as this point is arrived at, the contents of the flask are washed with the water of the wash-bottles into a distilling flask, and submitted to distillation. Dilute alco-

hol distills over and is collected in a 100 c.c. flask. If only 20–25 c.c. wash-water were used, the distillate, when it amounts to 80–85 c.c., will contain all the alcohol produced. This is then made up to 100 c.c. and its specific gravity taken. On referring to the alcohol tables, the weight of alcohol in the 100 c.c. is ascertained. From this a knowledge of the amount of fermentable sugars is arrived at. Sucrose yields 51 p.c. alcohol, dextrose 48–49 p.c. (Pasteur, *A. Ch.* [8] 58, 330), maltose 50.4–51.8 p.c. (O'Sullivan, *C. J.* 1876, 479). Hofmann, Graham, and Redwood (*C. J.* 5, 229) gave expression to the value of the specific gravity of distillate, in points or degrees of specific gravity lost by the saccharine solution fermented for various sugars. These factors are still employed in determining the original specific gravity of beer, from the alcohol it contains and the specific gravity of the residue after distillation. The residue left in the distilling flask mentioned above is with the washings made up to 100 c.c., the specific gravity of this solution subtracted from that of the solution before the yeast was added + 1—or 1000 if water be taken at 1000 instead of 1—will give approximately the specific gravity of a solution containing the amount of sugars or sugar fermented in 100 c.c. The average D of the sugars being known, the quantity fermented within 2 or 3 p.c. can be calculated from this. Inasmuch, however, as the value in specific gravity of the non-volatile products of the fermentation of the sugars has not been accurately determined, this mode of estimation can only be approximate.

• It has been proposed to estimate the amount of sugar or sugars by determining the amount of carbon dioxide evolved during fermentation. Pasteur (*l.c.*) gives 0.4665 g. CO<sub>2</sub> as the product of 1 g. dextrose. Jodlbauer (*Z. V.* 25, 308) states that dry maltose yields 49.54 p.c. CO<sub>2</sub> and dextrose 46.54 p.c. These figures are, no doubt, true also for all the fermentable 'on' and 'ose' sugars.

Some of the sugars when in the pure state are not fermented by yeast, but the presence of a small quantity of an easily fermentable sugar sets up the action. Pure galactose is not fermented by yeast; the presence of a little dextrose, levulose, or maltose sets up the process (Bourquelot, *C. R.* 106, 283; Tollens & Stone, *B.* 21, 1572; Stone & Tollens, *A.* 249, 287), the fermentation of galactose being as complete as that of dextrose if the suitable nourishment is present. Under the same condition sorbose ferments more slowly and less completely, arabinose and lactose very slowly and incompletely. Pure arabinose behaves like pure galactose. Sucrose is inverted by yeast, dextrose ferments easily, levulose less so, maltose still less, and raffinose less still. The other sugars ferment only when these are present; hence it should be possible to detect the presence of individual sugars from the specific rotatory power and  $K$  by fractional fermentation. With some varieties of yeast levulose ferments before dextrose (Dubourg, *C. R.* 110, 868). Again, some organisms are found to ferment the 'ose' sugars and to be incapable of fermenting the 'on' ones. A study of the action of these organisms will yield results valuable in the identification and estimation of the sugars.

8. *Action of acids.* All the di- and tri-sugars are converted into mono-sugars by the action of dilute mineral acids; this is accompanied by an alteration in the  $K$  and  $[a]$  of the solution. If this took place only with the high sugars, the reaction would be applicable in distinguishing the '-on' and '-ose-on' sugars from the '-ose'; but the  $K$  and  $[a]$  of these sugars are also affected by digestion with mineral acids, but much more slowly, so that the reaction is only available when carefully performed. If the sugar solution increase in  $K$ , and there is a material alteration in  $[a]$  on ten or twelve minutes' boiling with 2-3 p.c. sulphuric acid or hydrochloric acid, it may safely be inferred that a high sugar (di- or tri-) is present. Some organic acids act differently on the high sugars. Dilute citric acid inverts sucrose; it is without action, at least material action, in a short time on lactose (Jones, *l.c.*).

The invertive action of acids—except under well-defined conditions, such as the employment of hydrochloric acid by Clerget in hydrolysing sucrose—cannot, for the reason mentioned above, be employed in estimating these sugars.

Dextrose and substances capable of yielding it can be detected by acting on the material with nitric acid (1 pt. mat. 1 pt.  $H_2O$  and 5 pts. nitric acid, sp.gr. 1.15). Saccharic acid, recognisable by the microscopic appearance of its acid potassium salt, is produced (Sohst, *a. Tollens*, *A.* 245, 1). Levulose, galactose, sorbose, and arabinose do not yield this acid (Gans, Stone, *a. Tollens*, *B.* 21, 2148). Galactose, lactose, and raffinose, on treatment with nitric acid in the same way, yield mucic acid. This reaction has some quantitative value. Pasteur (*C. R.* 42, 349) obtained 75 to 78 p.c. mucic acid from galactose. The yield, however, varies very considerably with the quantity and strength of the acid employed. Kent *a. Tollens* (*A.* 227, 221) find on employing 1 pt. sugar, 12 pts. nitric acid, sp.gr. 1.15, allowing to crystallise in 1.5 to 2.0 pts. solution, and washing with 5 pts. water that galactose gives 77.4 p.c. mucic acid. Lactose treated in the same way gives 40 p.c., and raffinose (Rischbieth *a. Tollens*, *A.* 232, 172) 22-23 p.c. By using 1 g. dry sugar, or a quantity equal thereto, in a concentrated syrup, 4 g. nitric acid sp.gr. 1.25-1.24, heating gently until red fumes began to be evolved, then allowing the reaction to proceed until the violence was over, heating on a water-bath until red fumes ceased to be evolved, allowing to stand for 24 hours to crystallise, I obtained 73 p.c. mucic acid from galactose, 36.9 p.c. from dry lactose, and 28-30 p.c. from dry raffinose (O'Sullivan, *C. J.* 1886, 73). The mucic acid was collected on a tared filter, washed carefully with 50 c.c. water, dried in a vacuum over sulphuric acid, then at  $100^\circ$ , and weighed. By treating 0.5 g. mucic acid in the same way, the loss was 0.04-0.05 g. Corrected for this the above numbers become 80-81 p.c. for galactose and 40.5-41.5 p.c. for lactose. The number for raffinose was corrected.

The pentoses, and bodies from which they can be obtained, yield on digestion with strong hydrochloric acid, furfural, the detection of which is simple and definite. This reaction has been employed in the estimation of these sugars. It must not, however, be forgotten that the hexoses also yield furfural, although, no doubt, in very small

quantities (Günther *a. Tollens*, *B.* 23, 1751; de Chalmot *a. Tollens*, *B.* 24, 694; Stone, *B.* 24, 8019). The first difficulty to overcome was to determine the conditions under which the greatest yield of furfural was obtainable, the next to accurately determine the furfural. 2 to 5 g. of the material are digested with 100 c.c. hydrochloric acid, sp.gr. 1.06, and then distilling, returning the distillate until the reaction is complete; or the mixture of material and acid is submitted to distillation in a flask over a small flame, so that not more than 10 c.c. distillate pass over in five minutes, fresh acid being regularly added until a sample of the distillate ceases to give the reaction for furfural. The distillate is then neutralised with soda, acidified with a few drops of acetic acid, and made up to a definite volume. In this the furfural is estimated by a standard solution of phenylhydrazine, made by dissolving 2 g. phenylhydrazine chloride with 6 g. sodium acetate in 1 litre water. This is standardised with a solution of furfural of known strength (1 g. pure furfuramide in a little acetic acid to 1 ltr. water). Standardisation must be made before each set of determinations, as the phenylhydrazine solution loses its value in a short time. The titration is performed as follows: 25 c.c. of the distillate are mixed with a measured quantity of the phenylhydrazine solution, the mixture rapidly boiled and cooled; a little of the solution is filtered and boiled with twice its volume of Fehling's solution; if the phenylhydrazine is in excess reduction takes place, but if furfural is in excess there is no reduction. Trials are made until the equivalent amount of phenylhydrazine solution is found (Stone, *l.c.*). The dilute acidified solution is precipitated with phenylhydrazine acetate, the hydrazide collected on an asbestos filter and dried in a vacuum in a specially-constructed apparatus at  $50^\circ$ - $60^\circ$  until the weight becomes constant. The precipitation is always effected in the same volume of solution, so that allowance can be made for the solubility of the hydrazide. Arabinose yields on an average 48.72 p.c. and xylose 56.25 p.c. furfural (de Chalmot *a. Tollens*).

9. *The action of alkalis.* This can only be applied as a rough qualitative test. All the hexoses yield a brown colouration when boiled for a few minutes with a 3-4 p.c. solution sodium hydroxide. The '-on' sugars are not affected.

10. *The action of phenylhydrazine.* The melting-point of the osazones and hydrazides and composition thereof give good indication of the nature of the sugar whence they are prepared. For preparation and melting-point see individual sugars. Maquenne (*C. R.* 112, 799) finds that different sugars yield, with excess of phenylhydrazine, very different quantities of osazones. By heating 1 g. each sugar for one hour at  $100^\circ$  with 100 c.c. water, and 5 c.c. of a solution of phenylhydrazine acetate, containing in 1 litre 400 g. phenylhydrazine and 400 g. glacial acetic acid, cooling, collecting the precipitate, washing with 100 c.c. water and drying at  $110^\circ$ , he found sorbose gave 0.82 g., levulose 0.70, xylose 0.40, dry dextrose 0.32, arabinose 0.27, galactose 0.23, raffinose 0.15, lactose 0.11, maltose 0.11. There must, however, be some error or misunderstanding here, as there is no difficulty in getting 120

o. osazone from arabinose and more than 180 p.c. from levulose. C. O'S.

**SULPHACETIC ACID** v. **SULPHOACETIC ACID**.  
**SULPHAMIC ACID** and **SULPHAMATES**  
 $\text{SO}_2\text{NH}_2\text{OH}$  and  $\text{SO}_2\text{NH}_2\text{OM}$ . (*Amidosulphonic acid* and *Amidosulphonates*.) By passing dry  $\text{NH}_3$  over  $\text{SO}_3$ , Rose (P. 33, 81; 47, 471; 43, 183) obtained a compound  $\text{SO}_2\text{NH}_2$ . This compound, called by Rose 'sulphatammon,' is generally described as ammonium sulphamate  $\text{SO}_2\text{NH}_2\text{ONH}_4$ , but Divers a. Haga (C. J. 61, 948) have shown, fairly conclusively, that the compound is tri-ammonium imidosulphonate  $(\text{N}(\text{NH}_4))(\text{SO}_2\text{ONH})_2$  [ $=2\text{SO}_2\cdot 4\text{NH}_4$ ]; this salt is described under *Imidosulphonic acid* and its salts (v. **SULPHONIC ACIDS** AND **DERIVATIVES**, p. 600).

*Barium sulphamate*  $\text{SO}_2\text{NH}_2\text{O} > \text{Ba}$  seems to have been obtained by Berglund (B. 9, 1896) by boiling an aqueous solution of barium imidosulphonate  $\text{HN} < \text{SO}_2\text{O} > \text{Ba}$  (v. *Imidosulphonic acid* under **SULPHONIC ACIDS** AND **DERIVATIVES**, p. 600) till the solution reacted strongly acid, adding excess  $\text{BaOAg}$ , boiling so long as  $\text{NH}_3$  came off, filtering, removing excess of Ba by passing in  $\text{CO}_2$ , filtering, evaporating the filtrate to a small bulk, and allowing to stand. The salt crystallises in long, lustrous needles; it is not changed by heating to  $200^\circ$ , nor by boiling in solution, even in presence of  $\text{HClAg}$ .

Berglund (l.c.) says that a solution of *potassium sulphamate* is obtained by the reaction of nascent hydrogen with potassium oxyamidodisulphonate (v. *Oxyamidodisulphonic acid* under **SULPHONIC ACIDS** AND **DERIVATIVES**, p. 602), thus:  $\text{NHOH}\cdot\text{SO}_2\text{OKAg} + 2\text{H} = \text{NH}_2\cdot\text{SO}_2\text{OKAg} + \text{H}_2\text{O}$ . B. was unable to isolate the salt. Raschig (A. 241, 176) obtained the *potassium salt*  $\text{SO}_2\text{NH}_2\text{OK}$  by boiling potassium imidosulphonate  $\text{NH}(\text{SO}_2\text{OK})_2$  with a little water for some time, removing the  $\text{H}_2\text{SO}_4$  that was produced by  $\text{CaCO}_3$ , filtering from  $\text{CaSO}_4$ , evaporating, pouring off from  $\text{K}_2\text{SO}_4$  that separated, and allowing the syrupy mother-liquor to crystallise. The salt separated in large colourless, rhombic crystals. In 1878 Berglund prepared several sulphamates, viz. the salts of  $\text{NH}_4$ , Cd, Ca, Co, Cu, Pb, Li, Mn, Ni, Ag, Na, Sr, Tl, and Zn (*Lunds Universitets Arsskrift*, 13; abstract in Bl. [2] 29, 422).

**SULPHAMIC ACID**  $\text{SO}_2\text{NH}_2\text{OH}$ . This acid was obtained by Berglund (l.c.) by passing  $\text{H}_2\text{S}$  into a solution of the silver salt, filtering from  $\text{Ag}_2\text{S}$ , and evaporating over  $\text{H}_2\text{SO}_4$ . It forms large, translucent, rhombic crystals; the ratio  $a:b:c = .9945:1:1.056$  (Raschig, A. 241, 178). Easily sol. water, less sol. alcohol; aqueous solution only slowly decomposed to  $\text{NH}_3$ ,  $\text{H}_2\text{SO}_4$  on boiling; more rapidly decomposed if  $\text{HClAg}$  is added; not decomposed by heating to  $190^\circ$  (B., l.c.). A solution of the acid gives no pp. with  $\text{BaOAg}$ ; on boiling with  $\text{HClAg}$  and  $\text{BaCl}_2\text{Ag}$  a pp. of  $\text{BaSO}_4$  gradually forms. Raschig (l.c. p. 209) obtained sulphamic acid by saturating a solution of hydroxylamine hydrochloride with  $\text{SO}_2$ , allowing to stand for a little, and then evaporating on a water-bath ( $\text{NH}_4\text{OH}\cdot\text{HClAg} + \text{H}_2\text{SO}_4\text{OHAq} = \text{NH}_3\cdot\text{SO}_2\text{OHAq} + \text{HClAg} + \text{H}_2\text{O}$ ).

**SULPHAMIDE**  $\text{SO}(\text{NH}_2)_2$ . (*Sulphonamide*. *Sulphurylamide*.) The neutral amide of sul-

phuric acid is obtained by passing dry  $\text{NH}_3$  into cooled  $\text{SO}_2\text{Cl}_2$ , diluted with 15 to 20 vols.  $\text{CHCl}_3$ , to complete saturation, dissolving the pp. so produced in water, making strongly acid by  $\text{HNO}_3\text{Ag}$ , ppg. Cl as  $\text{AgCl}$  by addition of  $\text{AgNO}_3\text{Ag}$ , filtering, neutralising by  $\text{KOHAg}$ , and again ppg. by  $\text{AgNO}_3\text{Ag}$ , filtering from  $\text{SO}_2\text{NAg}$  (v. **SULPHIMIDE**, p. 587), adding more  $\text{AgNO}_3\text{Ag}$  and then  $\text{KOHAg}$ , warming and then cooling quickly, and collecting the pp. that forms. This pp. consists chiefly of  $\text{SO}_2(\text{NHAg})_2$ , but there is a small quantity of another Ag salt which must be removed. This is done by washing well, adding exactly enough  $\text{HClAg}$  to convert all Ag into  $\text{AgCl}$ , neutralising by  $\text{NH}_3\text{Ag}$ , adding  $\text{AgNO}_3\text{Ag}$ , filtering from the pp. of the foreign Ag salt, adding more  $\text{AgNO}_3\text{Ag}$  and then excess of  $\text{NH}_3\text{Ag}$ , when pure  $\text{SO}_2(\text{NHAg})_2$  is ppd. The salt is decomposed by exactly the proper quantity of  $\text{HClAg}$ ,  $\text{AgCl}$  is filtered off, the filtrate is evaporated *in vacuo* at a temperature not above  $40^\circ$ , and the liquid is allowed to remain *in vacuo* over  $\text{H}_2\text{SO}_4$ , when  $\text{SO}_2(\text{NH}_2)_2$  separates in large, colourless crystals (W. Traube, B. 26, 607). Sulphamide is very sol. water, less sol. dilute alcohol, insol. alcohol, ether, and other ordinary organic solvents; it softens at  $75^\circ$  and melts at  $81^\circ$ , begins to give off  $\text{NH}_3$  below  $100^\circ$ , no further decomposition occurring to  $250^\circ$ ; above  $250^\circ$  gives off acid vapours, and is completely decomposed. An aqueous solution of sulphamide is neutral; boiled with acids it gives  $\text{H}_2\text{SO}_4\text{Ag}$  and  $\text{NH}_3$ . Solutions of alkalis split off  $\text{NH}_3$ , and form alkali salts of  $\text{SO}_2\text{OH}\cdot\text{NH}_2$ . Small quantities of  $\text{H}_2\text{SO}_4\text{Ag}$  are formed after prolonged boiling. By adding  $\text{AgNO}_3\text{Ag}$  to solutions of sulphamide, and then  $\text{NH}_3\text{Ag}$ , a pp. of  $\text{SO}_2(\text{NHAg})_2$  is formed; other metallic derivatives of  $\text{SO}_2(\text{NH}_2)_2$  exist, but have not yet been isolated satisfactorily.

**IMIDO-SULPHAMIDE**  $\text{NH}(\text{SO}_2\text{NH}_2)_2$ , v. **SULPHAMID-AMIDE** (p. 587). M. M. P. M.

**SULPHANILIC ACID** v. vol. i. p. 154.

**SULPHANTIMONATES**, &c. For such salts as *sulphantimonates*, *sulpharsenates*, *sulphophosphates* v. *Thio-antimonates* &c., under **ANTIMONATES** &c.

**SULPHATAMMON** and **PARASULPHATAMMON** v. *Tri-ammonium imidosulphonate* and *Di-ammonium imidosulphonate* under *Imidosulphonic acid* and *salts*, a section of **SULPHONIC ACIDS** AND **DERIVATIVES**, p. 600.

**SULPHATES** and *allied salts*. *Salts of sulphuric acid*  $\text{H}_2\text{SO}_4$ . The compositions of the normal sulphates are expressed by the general formulae  $\text{M}_2\text{SO}_4$ ,  $\text{M}^+\text{SO}_4$ ,  $\text{M}^{++}(\text{SO}_4)_2$ , and  $\text{M}^{IV}(\text{SO}_4)_2$ ; the greater number of the acid sulphates come under such formulae as  $\text{M}^+\text{HSO}_4$ ,  $\text{M}^{++}\text{H}_2(\text{SO}_4)$ ,  $\text{M}^{IV}\text{H}(\text{SO}_4)_2$ ,  $\text{M}^{IV}\text{H}_2(\text{SO}_4)_2$ . All sulphates, whether normal, acid, or basic, may be represented by the formula  $n\text{MO}\cdot m\text{SO}_4\cdot x\text{H}_2\text{O}$ , where MO stands for a basic oxide. The sulphates are prepared (1) by the interaction of  $\text{H}_2\text{SO}_4\text{Ag}$  with metals, metallic oxides, or hydroxides; some metals react with dilute  $\text{H}_2\text{SO}_4\text{Ag}$ , giving sulphates and  $\text{H}_2$ , others react only with

## SULPHATES

not conc.  $\text{H}_2\text{SO}_4$ , giving sulphates and  $\text{SO}_2$  or  $\text{SO}$ , and  $\text{H}_2\text{S}$ , and sometimes  $\text{H}$  also; (2) by the interaction of  $\text{H}_2\text{SO}_4$  with salts of volatilisable or decomposable acids, e.g. with chlorides, nitrates, or carbonates; (3) by the direct combination of  $\text{SO}_2$  with metallic oxides; (4) by oxidising sulphides, by boiling with  $\text{HNO}_3$ , or by reacting with  $\text{Cl}$  in presence of water, or sometimes by heating in air, e.g.  $\text{FeSO}_4$ ,  $\text{CuSO}_4$ , and  $\text{ZnSO}_4$ ; (5) by double decomposition from other sulphates, e.g.  $\text{BaSO}_4$ ,  $\text{PbSO}_4$ . Most of the metallic normal sulphates are soluble in water;  $\text{BaSO}_4$  is insol. water,  $\text{PbSO}_4$  and  $\text{SrSO}_4$  nearly insol., and  $\text{CaSO}_4$  very slightly soluble. The basic sulphates are generally insoluble in water. Sulphates of metals whose oxides are strong bases—the alkali and alkaline earth metals—are not decomposed by heat alone; the sulphates of metals whose oxides are weak bases are decomposed by heating, giving off  $\text{SO}_2$ , or  $\text{SO}$ , and  $\text{O}$ , and leaving oxides, or metals if the oxides are reducible by heat. Sulphates are reduced by heating with charcoal, either to sulphides or oxides, with evolution of  $\text{CO}$  and  $\text{CO}_2$ , and also  $\text{SO}_2$  from the sulphates of weak bases. Many sulphates are decomposed completely by heating with  $\text{HCl}$  gas, giving chlorides (v. Hensgen, *B.* 9, 1671; 10, 259). Fusion with excess of alkali carbonate produces alkali sulphate and carbonate of the metal of the original sulphate. Many sulphates are reduced by strongly heating in a stream of  $\text{NH}_3$ , yielding sulphides, oxides, metal, or mixtures of these (v. Hodgkinson a. Trench, *C. N.* 66, 223). Several sulphates occur as minerals; e.g.  $\text{BaSO}_4$  (*heavyspar*),  $\text{CaSO}_4$  (*gypsum*),  $\text{SrSO}_4$  (*celestine*),  $\text{MgSO}_4$  (*Epsom salts*), &c.

**Aluminium sulphates.** The normal salt  $\text{Al}_2(\text{SO}_4)_3$ , 18aq occurs native as *feather alum*; it is prepared by heating clay with conc.  $\text{H}_2\text{SO}_4$  and boiling down the solution; also, according to Persoz (*A. Ch.* [3] 56, 102), by adding solution of alum or  $\text{AlCl}_3$  to a large excess of conc. boiling  $\text{H}_2\text{SO}_4$ , when anhydrous  $\text{Al}_2(\text{SO}_4)_3$  separates as a white powder. Gawalowski (*C. C.* 1886, 721) says that perfect octahedral crystals of  $\text{Al}_2(\text{SO}_4)_3$ , 17aq are obtained by saturating  $\text{H}_2\text{SO}_4$  with freshly pptd.  $\text{AlO}_3\text{H}_3$  and allowing to stand for some months. Crystallises with difficulty from water; crystallisation hastened by adding alcohol in which the salt is insol. (*P.*, *L.c.*). Concerning p.p.n. of  $\text{Al}_2(\text{SO}_4)_3 \cdot x\text{H}_2\text{O}$  from aqueous solutions by  $\text{H}_2\text{SO}_4$ , v. Eremin, *J. R.* 20, 468 (abstract in *C. J.* 56, 347). When heated gives off all water; heated to redness gives off  $\text{SO}_2$  and leaves  $\text{Al}_2\text{O}_3$ . Various *basic salts* are known; they are obtained by heating solution of  $\text{Al}_2(\text{SO}_4)_3$  with  $\text{AlO}_3\text{H}_3$ , or by partially pyg. solution of the normal salt, by  $\text{NH}_3$ , or by partial reduction of the normal salt by  $\text{Zn}$  (v. Maus, *P.* 11, 80; Debray, *Bl.* [2] 7, 1; Athanasesco, *C. R.* 103, 271; Crum, *A.* 89, 156; Marguerite, *C. R.* 90, 1854; Löwe, *J. pr.* 70, 428; Bley, *J. pr.* 89, 9).

The double salts  $\text{Al}_2(\text{SO}_4)_3 \cdot \text{M}_2\text{SO}_4$ , 24aq, where  $\text{M} = \text{NH}_4$ ,  $\text{Na}$ ,  $\text{K}$ ,  $\text{Rb}$ ,  $\text{Cs}$ ,  $\text{Ag}$ , or  $\text{Ti}$ , are *alums*. For expansions of alums v. Spring, *B.* 15, 1254, 1739; 17, 408.

Ammonia alum  $\text{Al}_2(\text{SO}_4)_3 \cdot (\text{NH}_4)_2\text{SO}_4$ , 24aq, prepared by adding  $(\text{NH}_4)_2\text{SO}_4$  or  $\text{NH}_4\text{Cl}$  to  $\text{Al}_2(\text{SO}_4)_3$ , so that the salts are in equivalent quantities, crystallises in octahedra; S.G. 1.56;

S. 5-27 a. v. v. at 100°. Heated to 190°,  $23\text{H}_2\text{O}$  is given off and  $\text{Al}_2(\text{SO}_4)_3 \cdot (\text{NH}_4)_2\text{SO}_4$  remains;  $\text{NH}_3$  begins to come off at c. 193° (Lupton, *C. J.* [2] 13, 201).

Potash alum  $\text{Al}_2(\text{SO}_4)_3 \cdot \text{K}_2\text{SO}_4$ , 24aq, prepared by mixing solutions of the two sulphates and evaporating, crystallises in regular octahedra; S.G. 1.7; S. 3-29 at 0°, 9.52 at 10°, 22 at 30°, 31 at 60°, 90 at 70°, 857 at 100°. The crystals effloresce in air. At 190°,  $23\text{H}_2\text{O}$  is given off (*L.*, *L.c.*). Also obtained in cubical crystals (v. Polis, *B.* 13, 360). Solution in water has an acid reaction, and dissolves  $\text{Zn}$  and  $\text{Fe}$ , giving off  $\text{H}$ .

Cæsium and rubidium alums v. Bunsen, *P.* 119, 1; Godeffroy, *B.* 181, 176; Redtenbacher, *J. pr.* 95, 148. Setterberg (*A.* 211, 100) gives S. in water from 0° to 80° (cf. Cæsium, vol. i. p. 658).

Silver alum v. Church a. Northote, *C. N.* 9, 155.

Sodium alum v. Pouissin, *Polytech. Centralbl.* 1852, 774; Zellner, *S.* 36, 183; and especially Augé, *C. R.* 110, 1139 (abstract in *C. J.* 58, 1059).

Thallium alum v. Lamy, *Bl.* [2] 11, 210. The double salts of  $\text{Al}_2(\text{SO}_4)_3$  with  $\text{FeSO}_4$ ,  $\text{MgSO}_4$ ,  $\text{MnSO}_4$ , and  $\text{ZnSO}_4$ , also crystallise with  $24\text{H}_2\text{O}$ . For double salts with  $\text{Fe}_2(\text{SO}_4)_3$ ,  $\text{Mn}_2(\text{SO}_4)_3$ , and  $\text{Cr}_2(\text{SO}_4)_3$ , v. Etard (*Bl.* [2] 31, 200). For a double salt with  $\text{PbSO}_4$ , v. Bailey (*C. S. I.* 6, 415).

**Ammonium sulphates.** The normal salt  $(\text{NH}_4)_2\text{SO}_4$  is found in certain volcanic districts; it is prepared by neutralising  $\text{H}_2\text{SO}_4$  by  $\text{NH}_3$  or  $(\text{NH}_4)_2\text{CO}_3$  and evaporating. Crystallises in clear rhombic forms, is isomorphous with  $\text{K}_2\text{SO}_4$  (Mitscherlich, *P.* 18, 168). S.G. 1.761 (Playfair a. Joule, *C. S. Mem.* 2, 401); for S.G. from 10° to 100° v. Spring (*B.* 15, 1940). Melts at c. 140° (Marchand, *P.* 42); decomposes above 280°; according to Johnson a. Chittenden (*Am. S.* [3] 15, 131), gives  $\text{NH}_4\text{HSO}_4$  and  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ , and at incipient redness gives  $\text{SO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{NH}_3$ . Absorbs dry  $\text{HCl}$ , forming some  $\text{NH}_4\text{Cl}$  (v. Thomas, *C. J.* 33, 372). S. 71 at 0°, 73.65 at 10°, 76.3 at 20°, 78.95 at 30°, 81.6 at 40°, 84.25 at 50°, 86.9 at 60°, 89.55 at 70°, 92.2 at 80°, 94.85 at 90°, 97.5 at 100° (Alluard, *C. R.* 59, 500). Insol. absolute alcohol. For S.G. of  $(\text{NH}_4)_2\text{SO}_4$  from 1 to 50 p.c.  $(\text{NH}_4)_2\text{SO}_4$ , v. Schiff (*A.* 108, 338; 110, 74). H.F.  $[\text{N}^2\text{H}^+\text{S}_2\text{O}_7] = 284,800$  (Thomsen, *J. pr.* 21, 477). The acid salt  $\text{NH}_4\text{HSO}_4$  crystallises from solution of  $(\text{NH}_4)_2\text{SO}_4$  in hot conc.  $\text{H}_2\text{SO}_4$  in long rhombic prisms, S.G. 1.787 (Schiff, *A.* 107, 83). S. 100 in cold water. Two other acid salts have been isolated:

(1)  $(\text{NH}_4)_3\text{H}(\text{SO}_4)_2$ ,  $[\text{N}^2\text{H}^+\text{S}_2\text{O}_7] = 3(\text{NH}_4)_2\text{SO}_4 \cdot \text{SO}_3 \cdot \text{H}_2\text{O}$  or  $3(\text{NH}_4)_3\text{O}_4\text{S}_2\text{O}_7 \cdot \text{H}_2\text{O}$  by adding the proper quantity of  $\text{H}_2\text{SO}_4$  to  $(\text{NH}_4)_2\text{SO}_4$  (Marignac, *Ann. M.* [5] 12, 88); (2)  $(\text{NH}_4)_3\text{H}_2\text{S}_2\text{O}_7$ ,  $[\text{N}^2\text{H}^+\text{S}_2\text{O}_7] = (\text{NH}_4)_3\text{O}_4\text{S}_2\text{O}_7$  by heating dry  $(\text{NH}_4)_2\text{SO}_4$  with  $\text{SO}_2$  to 100° in a closed tube and distilling off excess of  $\text{SO}_2$  at c. 60° (Weber, *B.* 17, 2501).

**Antimony sulphates.** The normal salt  $\text{Sb}_2(\text{SO}_4)_3$  is obtained by dissolving  $\text{Sb}_2\text{O}_3$  in boiling conc.  $\text{H}_2\text{SO}_4$  (c. 98 p.c.  $\text{H}_2\text{SO}_4$ ), recrystallising from conc.  $\text{H}_2\text{SO}_4$ , and drying on a porous tile over  $\text{H}_2\text{SO}_4$  (Adie, *O. J.* 57, 540; where an account of the action of  $\text{H}_2\text{SO}_4$  of different concentrations, and of  $\text{SO}_2$  on  $\text{Sb}_2\text{O}_3$ , will be found, with references to older papers).

## SULPHATES.

**Barium sulphates.** The normal salt  $\text{BaSO}_4$  occurs native as *heavy spar*. Prepared by adding dilute  $\text{H}_2\text{SO}_4$  or dilute solution of a sulphate to solution of a salt of Ba, washing, and drying. A white solid; S.G. 4.525 (G. Rose, P. 75, 409; v. also Schröder, P. 106, 226; a. Wiedemann; P. M. [5] 15, 371). Obtained as a crystalline powder by fusing 1 part  $\text{K}_2\text{SO}_4$  with  $\frac{4}{3}$  parts dry  $\text{BaCl}_2$  in a closed crucible, and washing with water (Manross, A. 82, 348); also by heating dilute  $\text{BaCl}_2$  aq with slight excess of  $\text{H}_2\text{SO}_4$  aq to  $245^\circ$  (Scheerer a. Drechsel, J. pr. [2] 7, 68). H.F.  $[\text{Ba}_2\text{O}^+\cdot\text{S}] = \text{c. } 338,000$  (Th. 3, 516). Insol. water; 1 part dissolves in c. 23,000 parts cold, and in c. 4,900 parts hot,  $\text{HCl}$  aq S.G. 1.03, and in c. 9,200 parts  $\text{HNO}_3$  aq S.G. 1.02. Struve (Fr. 9, 34) gives S. of  $\text{BaSO}_4$  in conc.  $\text{H}_2\text{SO}_4$  as 5.69, and 15.89 in Nordhausen acid.  $\text{BaSO}_4$  is partly decomposed by boiling with conc. solution of an alkali carbonate, or by fusion with alkali carbonate; Spring (Bl. [2] 44, 166) found that some  $\text{BaCO}_3$  was formed by compressing  $\text{BaSO}_4$  and  $\text{Na}_2\text{CO}_3$  at a pressure of c. 6,000 atmospheres.

An acid salt  $\text{BaSO}_4\cdot\text{H}_2\text{SO}_4$  is formed by dissolving  $\text{BaSO}_4$  in hot conc.  $\text{H}_2\text{SO}_4$ , S.G. 1.843, and heating to  $100^\circ$  (v. Garside, C. N. 31, 245).

**Beryllium sulphates.** The normal salt  $\text{BeSO}_4$  aq is formed by dissolving  $\text{BeCO}_3$  in dilute  $\text{H}_2\text{SO}_4$  aq and concentrating the slightly acid liquid. For crystalline form v. Topsøe (W. A. B. 66 [2nd part], 5). According to Klatzko (Fr. 106, 233) the salt crystallises with  $7\text{H}_2\text{O}$ . Various basic salts are obtained by the action of  $\text{BeCO}_3$  or Zn on solution of the normal salt.

**Bismuth sulphates.** The normal salt  $\text{Bi}_2(\text{SO}_4)_3$  is best prepared by dissolving  $\text{Bi}_2\text{S}_3$  in conc.  $\text{H}_2\text{SO}_4$  heated to commencing vapourisation; on cooling the salt separates in lustrous, very deliquescent, needles (Hensgen, R. T. C. 4, 401; cf. Schultz-Sellack, B. 4, 13). For the action of heat on  $\text{Bi}_2(\text{SO}_4)_3$ , v. Bailey (C. J. 51, 680). An acid salt  $\text{BiH}(\text{SO}_4)_2$  aq was obtained by Leist (A. 160, 29) by dissolving  $\text{Bi}_2\text{O}_3$  in dil.  $\text{H}_2\text{SO}_4$  aq under definite conditions. Basic salts are also formed by the reaction of dilute  $\text{H}_2\text{SO}_4$  aq with  $\text{Bi}_2\text{O}_3$  (v. Heintz, P. 63, 55, 567), and by the action of  $\text{H}_2\text{O}$  on the normal salt (cf. Hensgen, l.c.).

According to R. H. Adie (*priv. comm.*), acid salts  $\text{BiH}(\text{SO}_4)_x$  aq ( $x = \text{probably } 1\frac{1}{2} \text{ and } 3$ ) crystallise from solutions of  $\text{Bi}_2\text{O}_3$  or  $\text{Bi}_2(\text{SO}_4)_3$  in  $\text{H}_2\text{SO}_4$  aq of concentrations varying from  $\text{H}_2\text{SO}_4\cdot\text{H}_2\text{O}$  to c.  $\text{H}_2\text{SO}_4\cdot 5\text{H}_2\text{O}$ ; from acid of the concentration  $\text{H}_2\text{SO}_4\cdot 6\text{H}_2\text{O}$ , a basic salt crystallises, probably  $\text{Bi}_2\text{OH}_2\text{SO}_4\cdot\text{H}_2\text{O}$ .

**Cadmium sulphates.** The normal salt  $\text{CdSO}_4$  aq is obtained by dissolving Cd in dilute  $\text{H}_2\text{SO}_4$  aq, and concentrating, by boiling, the acid solution (von Hauer, J. pr. 73, 372). Various other hydrates have been isolated. H.F.  $[\text{Cd}_2\text{O}^+\cdot\text{S}] = 221,550$  (Th. 3, 516).  $\text{CdSO}_4$  combines with  $\text{NH}_3$  to form various compounds (v. H. Rose, P. 20, 152; Malaguti a. Sarzeau, A. Oh. [8] 9, 481; Isambert, C. R. 70, 456; Müller, A. 149, 70). Forms double salts with  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{MgSO}_4$ , and  $\text{Na}_2\text{SO}_4$ ; these salts crystallise with 6aq (von H., l.c.). The double salt with  $\text{Al}_2(\text{SO}_4)_3$  is an alum.

**Cesium sulphates.** Normal salt  $\text{Cs}_2\text{SO}_4$  by neutralising  $\text{H}_2\text{SO}_4$  aq by  $\text{Cs}_2\text{CO}_3$  and evapo-

rating. Short needles, not hygroscopic; insol. alcohol. m.p.  $158.7^\circ$  at  $-2^\circ$ . The acid salt  $\text{CaHSO}_4$ , formed by reacting on  $\text{CaSO}_4$  with excess of  $\text{H}_2\text{SO}_4$ , crystallises in small rhombic prisms (Bunsen a. Kirchhoff, P. 113, 842).

**Calcium sulphates.** The normal salt  $\text{CaSO}_4$  occurs native as *anhydrite*, and the dihydrate  $\text{CaSO}_4\cdot 2\text{aq}$  as *gypsum*, *alabaster*, and *selenite*.  $\text{CaSO}_4$  is obtained in crystals by fusing  $\text{K}_2\text{SO}_4$  with excess of  $\text{CaCl}_2$  and washing (Manross, A. 82, 348; cf. Mitscherlich, P. 21, 321).  $\text{CaSO}_4\cdot 2\text{aq}$  is formed by ppg. fairly conc.  $\text{CaCl}_2$  aq by dil.  $\text{H}_2\text{SO}_4$  aq or solution of a sulphate, evaporating, and washing the solid that separates.  $\text{CaSO}_4\cdot 2\text{aq}$  is said to be formed by the interaction of  $\text{CaCO}_3$  and S moistened with water (Polacci, G. 1874, 177, 215).  $\text{CaSO}_4$  has S.G. 2.964, and  $\text{CaSO}_4\cdot 2\text{aq}$  has S.G. 2.31 (v. also McCaleb, Am. 11, 35). S. for  $\text{CaSO}_4\cdot 19$  at  $0^\circ$ ,  $200^\circ$ ,  $200^\circ$ ,  $214$  at  $40^\circ$ ,  $208$  at  $60^\circ$ ,  $195$  at  $80^\circ$ ,  $174$  at  $100^\circ$  (Marignac, A. Ch. [5] 1, 274); S. for  $\text{CaSO}_4\cdot 2\text{aq}$   $2119$  at  $16.5^\circ$ ,  $2353$  at  $22^\circ$  (Cossa, G. 1873, 135); S. for  $\text{CaSO}_4\cdot 2\text{aq}$  in glycerin,  $957$  at ordinary temperature, S. increases as temperature rises (Asselin, C. R. 76, 884). According to Raupenstauch (C. C. 1888, 821) the solubility in water of gypsum increases to  $32^\circ$ , is constant from  $32^\circ$  to  $38^\circ$ , and decreases above  $38^\circ$ . Gypsum loses  $2\text{H}_2\text{O}$  when heated to  $80^\circ$  in a stream of dry air; when the  $\text{CaSO}_4$  thus produced is moistened it takes up  $2\text{H}_2\text{O}$ , becomes crystalline, and expands. The dehydrated  $\text{CaSO}_4$ , obtained by heating gypsum to  $160^\circ$  takes up water very slowly; if the gypsum is heated to c.  $300^\circ$  the  $\text{CaSO}_4$  formed combines with water with extreme slowness (v. Schott, D. P. J. 202, 52, 355, 513; cf. *Plaster of Paris*, under CEMENTS, in DICTIONARY OF APPLIED CHEMISTRY, vol. i. p. 468).

According to Potilitz (J. R. 1893 [1] 201, 207)  $\text{CaSO}_4\cdot 2\text{aq}$  slowly gives off water at  $62^\circ$ – $65^\circ$  till the hydrate  $2\text{CaSO}_4\cdot \text{aq}$  is formed;  $\text{CaSO}_4$  prepared by heating  $\text{CaSO}_4\cdot 2\text{aq}$  to  $180^\circ$ – $170^\circ$  absorbs  $\text{H}_2\text{O}$  from ordinary air until  $2\text{CaSO}_4\cdot \text{aq}$  is formed when absorption of water ceases. The hydrate  $2\text{CaSO}_4\cdot \text{aq}$  absorbs water from air saturated with moisture, forming  $\text{CaSO}_4\cdot 2\text{aq}$ . The water of crystallisation of gypsum is not equally firmly retained; P. writes the formula  $2\text{CaSO}_4\cdot 4\text{aq}$ ; three-quarters of the  $\text{H}_2\text{O}$  is much more readily given off than the other fourth. The hydrate  $2\text{CaSO}_4\cdot \text{aq}$  is more soluble in water than the dihydrate  $\text{CaSO}_4\cdot 2\text{aq}$ .

An acid salt  $\text{CaH}_2(\text{SO}_4)_2$  is said by Berzelius to be formed by digesting  $\text{CaSO}_4$  with  $\text{H}_2\text{SO}_4$  aq at  $80^\circ$ – $100^\circ$ ; it is decomposed by moist air to the normal salt and  $\text{H}_2\text{SO}_4$ . For double salts with alkali and alkaline earth sulphates v. Fassbender (B. 9, 1358; 11, 1968); Struve (Bl. [2] 12, 348); Ditté (C. R. 84, 86); Popp (A. Suppl. 8, 1); Hannay (C. J. 32, 399).

**Cerium sulphates.** The normal cerous sulphate,  $\text{Ce}_2(\text{SO}_4)_3\cdot x\text{H}_2\text{O}$  ( $x$  being probably 6, 8, 9, and 12) is obtained in colourless crystals by evaporating a solution of  $\text{Ce}_2(\text{CO}_3)_3$  in dilute  $\text{H}_2\text{SO}_4$  aq, or a solution of  $\text{CeO}_2$  in  $\text{H}_2\text{SO}_4$  aq saturated with  $\text{SO}_2$ . The normal ceric salt  $\text{Ce}(\text{SO}_4)_2\cdot 4\text{aq}$  forms, in yellow crystals, from a solution of  $\text{CeO}_2$  in dilute  $\text{H}_2\text{SO}_4$  aq. Cerous-ceric sulphates,  $x\text{Ce}_2(\text{SO}_4)_3\cdot y\text{Ce}(\text{SO}_4)_2\cdot 2\text{aq}$ , are obtained by dissolving  $\text{CeO}_2$  in conc.  $\text{H}_2\text{SO}_4$  and evaporating. Basic salts are formed by the

interaction of water with the normal salts. Double salts of  $\text{Ce}_2(\text{SO}_4)_3$  with  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{K}_2\text{SO}_4$ , and  $\text{Na}_2\text{SO}_4$  are known (v. Marignac, *A. Ch.* [4] 80, 57; Czudnowicz, *J. pr.* 30, 19; Hermann, *J. pr.* 92, 126; Zschiesche, *J. pr.* 107, 65; Rammelsberg, *B.* 6, 85; Jolin, *Bl.* [2] 21, 523; Wyruboff, *Bl.* [8] 2, 745; Wing, *Am. S.* [2] 40, 856).

**Chromium sulphates.** The normal chromous salt  $\text{CrSO}_4 \cdot 7\text{aq}$  was obtained by Moissan (*Bl.* [2] 37, 296) by dissolving the acetate in warm dilute  $\text{H}_2\text{SO}_4\text{aq}$ , crystallising, and drying between paper, all operations being conducted in an atmosphere of  $\text{CO}_2$  (for directions for making  $\text{Cr}(\text{C}_2\text{H}_3\text{O}_2)_3$ , v. Nitrogen, *Preparation*, vol. iii. p. 557). Blue crystals; isomorphous with  $\text{FeSO}_4 \cdot 7\text{aq}$ . S. 12-35 at  $0^\circ$ ; sl. sol. alcohol. Absorbs O rapidly from air, and acts as a strong reducer. A monohydrate  $\text{CrSO}_4 \cdot \text{aq}$  was obtained as a white crystalline powder by adding the acetate to excess of conc.  $\text{H}_2\text{SO}_4$  (M., l.c.). Forms a double salt,  $\text{CrSO}_4 \cdot \text{K}_2\text{SO}_4 \cdot 6\text{aq}$  (Péligot, *A. Ch.* [8] 12, 539).

The normal chromic salt  $\text{Cr}_2(\text{SO}_4)_3 \cdot x\text{H}_2\text{O}$  exists in two forms. (1) Violet,  $x=15$  (Schrötter, *P.* 53, 5'6), =18 (Stewart, *A.* 126, 97); by digesting 1 pt.  $\text{CrO}_3\text{H}_2$  dried at  $100^\circ$  with 1 to 1½ pts. conc.  $\text{H}_2\text{SO}_4$  in a closed vessel, till a mass of greenish-blue crystals is formed, dissolving these crystals in water, ppg. by absolute alcohol, dissolving again in water, adding alcohol till ppn. just begins, covering the vessel with moist parchment-paper, and allowing to crystallise slowly. Regular octahedra; red-violet in reflected light, garnet-red in transmitted light; S. 120 in cold water (Schrötter, *P.* 53, 516; Löwel, *A. Ch.* [3] 40, 42). (2) Green,  $x=5$ . By heating the violet salt to  $100^\circ$ ; the salt melts, gives off water, and then solidifies to a green amorphous mass. Also formed by dissolving  $\text{CrO}_3\text{H}_2$  in conc.  $\text{H}_2\text{SO}_4$  at  $50^\circ$ - $60^\circ$ , and evaporating quickly. Easily sol. alcohol; whereas the violet salt is insol. alcohol.

Addition of a cold solution of a Ba salt ppts. all SO, from a solution of the violet form, but boiling is needed to complete the ppn. from the green variety. According to Etard (*C. R.* 84, 1089), the difference between the two forms is one of hydration only (but v. Chromium salts, vol. ii. p. 167; and v. also Recoura, *C. R.* 113, 857).

**Basic salts** are obtained by adding a little  $\text{NH}_4\text{aq}$  to solution of the normal salt, also by digesting the normal salt with  $\text{CrO}_3\text{H}_2$ , or excess of  $\text{CrO}_3\text{H}_2$  with  $\text{H}_2\text{SO}_4\text{aq}$  (v. Schrötter, *P.* 53, 516; Stewart, *A.* 126, 97; Schiff, *A.* 154, 167, 172; Recoura, *C. R.* 112, 1439). According to Traube (*A.* 66, 87), an acid salt,  $\text{Cr}_2(\text{SO}_4)_3 \cdot \text{H}_2\text{SO}_4$ , is formed by heating either variety of the normal salt with excess of  $\text{H}_2\text{SO}_4$  till vaporisation of the acid begins, and allowing to cool (Schrötter [l.c.] regarded this as an insoluble variety of the normal salt); insol. water, not acted on by cold KOHAq, heated strongly gives  $\text{Cr}_2\text{O}_3$ , SO, and O.

$\text{Cr}_2(\text{SO}_4)_3$  forms many double salts; those with the alkali sulphates have the composition  $\text{Cr}_2(\text{SO}_4)_3 \cdot \text{M}_2\text{SO}_4 \cdot 24\text{aq}$ , and are alums.

Ammonia chrome-alum is ppd. by adding  $(\text{NH}_4)_2\text{SO}_4$  to a saturated solution of violet  $\text{Cr}_2(\text{SO}_4)_3$ ; also formed by mixing  $(\text{NH}_4)_2\text{SO}_4\text{aq}$  and  $\text{Cr}_2(\text{SO}_4)_3\text{aq}$ , and evaporating; also by mixing  $\text{Cr}_2(\text{SO}_4)_3\text{aq}$  (violet) with  $(\text{NH}_4)_2\text{CrO}_4\text{aq}$ ,

adding a little  $\text{H}_2\text{SO}_4$  according to vaporisation. Crystallises in ruby-red octahedra; S.G. 1.788. Effloresces slowly in air. Solution in water is violet; at  $75^\circ$  it becomes green, but slowly returns to violet on standing for some weeks (regarding this change v. Chromium salts, vol. ii. p. 167).

Potash chrome-alum is produced similarly to the ammonia salt; also by heating  $\text{K}_2\text{Cr}_2\text{O}_7$  with conc.  $\text{H}_2\text{SO}_4$ , more quickly in presence of a reducer, e.g. SO. Crystallises in large dark-purple octahedra; S. 14-5 in cold water. Solution in water is grey-blue with tinge of red; heated to  $70^\circ$ - $80^\circ$  it becomes green and non-crystallisable, but returns to violet after standing for some weeks. For Soda chrome-alum v. Schrötter (*P.* 53, 513). For double salts of  $\text{Cr}_2(\text{SO}_4)_3$  with  $\text{Al}_2(\text{SO}_4)_3$ ,  $\text{Fe}_2(\text{SO}_4)_3$ , and  $\text{Mn}_2(\text{SO}_4)_3$ , v. Etard (*Bl.* [2] 31, 200); for double salts of the form  $\text{Cr}_2(\text{SO}_4)_3 \cdot \text{M}_2\text{SO}_4$ , where M=Li, K, or Na, v. Warnicke (*P.* 159, 572).

For description of "other double salts of  $\text{Cr}_2(\text{SO}_4)_3$  with alkali sulphates, v. Klobb, *C. R.* 117, 311 (Abstract in *C. J.* 64 [ii], 573).

**Cobalt sulphates.**—The normal cobaltous salt  $\text{CoSO}_4 \cdot 7\text{aq}$  occurs native as *biberite*; prepared by dissolving Co, CoO, or  $\text{CoCO}_3$  in dilute  $\text{H}_2\text{SO}_4\text{aq}$ , and evaporating. Forms carmine-red crystals, isomorphous with  $\text{FeSO}_4 \cdot 7\text{aq}$ ; S.G. 1.918 at  $15^\circ$  (Thorpe & Watts, *C. J.* 87, 102). Unchanged in air; loses all water by heating, and gives  $\text{CoSO}_4$  as a red powder, not decomposed easily by heat; S.G. 3.472 at  $15^\circ$  (T. & W., l.c.). Klobb (*C. R.* 114, 836) obtained the anhydrous salt in crystals by mixing  $\text{CoSO}_4 \cdot 7\text{aq}$  with excess of  $(\text{NH}_4)_2\text{SO}_4$  and heating in a partly-closed crucible, out of contact with the gases of the flame, till  $(\text{NH}_4)_2\text{SO}_4$  was all volatilised. The hexahydrate  $\text{CoSO}_4 \cdot 6\text{aq}$  separates from solutions of Co or  $\text{CoCO}_3$  in  $\text{H}_2\text{SO}_4\text{aq}$  at  $40^\circ$ - $50^\circ$ ; it is isomorphous with the corresponding salts of Mg, Ni, and Zn (Marignac). For other hydrates, with 4aq and aq, v. Fröhde (*J.* 1866, 244); Vortmann (*B.* 15, 1888).  $\text{CoSO}_4 \cdot 7\text{aq}$  is insol. alcohol; S. water 30.5 at  $10^\circ$ , 36.4 at  $20^\circ$ , 40 at  $29^\circ$ , 46.3 at  $35^\circ$ , 55.2 at  $50^\circ$ , 60.4 at  $60^\circ$ , 65.7 at  $70^\circ$  (stated as parts  $\text{CoSO}_4$  dissolved by 100 parts water; Tobler, *A.* 95, 193). Thomsen (*Th.* 3, 516) gives H.F.  $[\text{Co}_2\text{O}_3 \cdot 7\text{H}_2\text{O}] = 234,000$ . By electrolysis  $\text{CoSO}_4\text{aq}$  in presence of  $\text{K}_2\text{SO}_4$  and  $\text{H}_2\text{SO}_4$ , under special conditions, Marshall obtained  $\text{Co}_2(\text{SO}_4)_3$  along with  $\text{K}_2\text{S}_2\text{O}_8$  (*C. J.* 59, 760).

**Basic salts** are formed by addition of a little  $\text{NH}_4\text{aq}$  to hot  $\text{CoSO}_4\text{aq}$ , also by digesting  $\text{CoSO}_4\text{aq}$  with  $\text{CoCO}_3$  (v. Habermann, *M.* 5, 442; Athanasesco, *C. R.* 103, 271).

For double salts with  $\text{FeSO}_4$ ,  $\text{MgSO}_4$ ,  $\text{MnSO}_4$ , and  $\text{ZnSO}_4$ , v. Vohl (*A.* 94, 57).

**Normal cobaltic sulphate**  $\text{Co}_2(\text{SO}_4)_3$  was obtained by Marshall (*C. J.* 59, 767) by electrolysis  $\text{CoSO}_4\text{aq}$  in presence of  $\text{H}_2\text{SO}_4$ , under special conditions. A blue crystalline powder, unchanged in a stoppered bottle in ordinary air, but decomposes rapidly in dry air; sol. water, with evolution of O; sol. conc.  $\text{H}_2\text{SO}_4$ ; in  $\text{HClAq}$  forms  $\text{CoCl}_2$  and gives off Cl.

**Copper sulphates.** Only salts corresponding with the oxide  $\text{CuO}$  have been isolated. The normal salt  $\text{CuSO}_4$  is obtained by dissolving Cu in hot conc.  $\text{H}_2\text{SO}_4$ , decanting the hot solution, and allowing to cool; also by adding conc.

crystals of  $\text{CuSO}_4 \cdot 5\text{aq}$  to c.  $230^\circ$  as long as they lose weight. Klobb (*C. R.* 114, 836) obtained  $\text{CuSO}_4$  in crystals by heating a mixture of the hydrated salt and excess of  $(\text{NH}_4)_2\text{SO}_4$  in a partly closed crucible till all  $(\text{NH}_4)_2\text{SO}_4$  had volatilised. A white crystalline powder; S.G. 8.606 at  $15^\circ$  (Thorpe & Watts, *C. J.* 37, 102). Partly decomposed at red heat, wholly at white heat, to  $\text{SO}_3$ ,  $\text{O}$ , and  $\text{CuO}$ . Reduced by heating to redness with charcoal, giving  $\text{Cu}$ ,  $\text{SO}_2$ , and  $\text{CO}_2$ . At a higher temperature some  $\text{CuS}$  is said to be formed; also reduced to  $\text{Cu}$  by heating in  $\text{H}_2$ ; heated in  $\text{PH}_3$  gives off  $\text{H}_2\text{O}$ , and leaves a mixture of sulphide and phosphide of  $\text{Cu}$ .  $\text{HCl}$  gas forms  $\text{CuCl}_2$  and  $\text{H}_2\text{SO}_4$ .  $\text{CuSO}_4$  acts as a powerful dehydrating agent; it rapidly absorbs water, forming  $\text{CuSO}_4 \cdot 5\text{aq}$ .  $\text{H.F.}[\text{Cu}_2\text{S}_2\text{O}_7] = 182.500$  (*Th.* 3, 516).

The pentahydrate  $\text{CuSO}_4 \cdot 5\text{aq}$  (blue vitriol) is prepared by dissolving  $\text{Cu}$  in hot conc.  $\text{H}_2\text{SO}_4$ , evaporating, and recrystallising from water the solid that separates. At c.  $20^\circ$  there is a very slight reaction, with formation of  $\text{Cu}_2\text{S}$  and  $\text{CuSO}_4$ ; at c.  $270^\circ$  the reaction is  $\text{Cu} + 2\text{H}_2\text{SO}_4 = \text{CuSO}_4 + \text{SO}_2 + 2\text{H}_2\text{O}$  (Pickering, *C. J.* 33, 112). According to Abthion (*R. P.* 81, 314),  $\text{CuSO}_4 \cdot 5\text{aq}$  free from nitrate, is obtained by dissolving  $\text{Cu}$  in a warm mixture of dilute  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ , and crystallising. (For preparation of commercial blue vitriol v. *DICTIONARY OF APPLIED CHEMISTRY*, vol. i. p. 608.) Large blue, triclinic crystals; S.G. 2.284 at  $15^\circ$  (Thorpe & Watts, *C. J.* 37, 102). Solubility in water is given by Poggiale (*A. Ch.* [3] 8, 463) as follows:—

	S.			S.	
Temp.	$\text{CuSO}_4 \cdot 5\text{aq}$	$\text{CuSO}_4$	Temp.	$\text{CuSO}_4 \cdot 5\text{aq}$	$\text{CuSO}_4$
$0^\circ$	31.61	18.20	$60^\circ$	77.39	38.83
10	36.95	20.92	70	94.40	45.06
20	42.31	23.55	80	118.03	53.15
30	48.81	26.63	90	156.44	64.23
40	56.90	30.29	100	203.32	75.25
50	65.83	34.14			

Gerlach (*D. P. J.* 181, 129) gives the following table:—

Percentage $\text{CuSO}_4 \cdot 5\text{aq}$	S.G. of solution	Percentage $\text{CuSO}_4 \cdot 5\text{aq}$	S.G. of solution
2	1.0126	14	1.0933
4	1.0254	16	1.1063
6	1.0384	18	1.1208
8	1.0516	20	1.1354
10	1.0649	22	1.1501
12	1.0785	24	1.1659

Insol. absolute alcohol; S. in 40 p.c. alcohol at  $15^\circ = .25$  (Schiff). Fairly sol. glycerin. Effloresces in dry air, giving off  $2\text{H}_2\text{O}$ ; heated for some time to  $100^\circ$  loses  $4\text{H}_2\text{O}$ , the last  $\text{H}_2\text{O}$  is removed at c.  $230^\circ$ . For dissociation—pressures of water given off at various temperatures v. Lescaeur (*C. R.* 102, 1466). Solution in  $\text{HCl}$  aq gives  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  on evaporation. The dry salt, in powder, absorbs  $\text{HCl}$ , the water of crystallisation being set free (Kane, *A.* 19, 1); several compounds of  $\text{CuSO}_4$ ,  $\text{HCl}$ , and  $\text{H}_2\text{O}$  are formed according to Latschinoff (*J. R.* 1888 [1] 586, 657, 707; abstract in *B.* 22 Ref. 192). Combines with  $\text{NH}_3$ , forming  $\text{CuSO}_4 \cdot 5\text{NH}_3$ , all water of crystallisation being removed (*L.*, *L.*).

Other hydrated copper sulphates are (1)

$\text{CuSO}_4 \cdot 6\text{aq}$  and (2)  $\text{CuSO}_4 \cdot 7\text{aq}$ , obtained by Lecoq de Boisbaudran (*C. R.* 65, 1240), the former by placing a crystal of  $\text{NiSO}_4 \cdot 4\text{aq}$  in a warm supersaturated solution of  $\text{CuSO}_4 \cdot 5\text{aq}$ , to which a few drops of  $\text{H}_2\text{SO}_4$  aq had been added, and the latter by placing a crystal of  $\text{FeSO}_4 \cdot 7\text{aq}$  in the mother-liquor from the first-named hydrate; (3)  $\text{CuSO}_4 \cdot 3\text{aq}$ , by keeping  $\text{CuSO}_4 \cdot 5\text{aq}$  in dry air at  $25^\circ$ – $30^\circ$  (Magnier de la Source, *C. R.* 83, 899); also by pouring cold conc.  $\text{CuSO}_4$  aq into  $\text{H}_2\text{SO}_4$  aq, S.G. 1.7, and washing the pp. with small quantities of absolute alcohol (Thorpe & Watts, *C. J.* 37, 104); (4)  $\text{CuSO}_4 \cdot 2\text{aq}$  by keeping the pentahydrate *in vacuo* at  $20^\circ$  for some days, or by pouring conc.  $\text{CuSO}_4$  aq into cold conc.  $\text{H}_2\text{SO}_4$ , and washing the pp. with absolute alcohol (*T. a. W.*, *L.*); (5)  $\text{CuSO}_4$  aq by heating powdered pentahydrate at  $110^\circ$  till it ceases to lose weight (*T. a. W.*, *L.*). *T. a. W.* (*L.*) give the S.G. of these hydrates, at  $15^\circ$ , as: monohydrate, 3.289; dihydrate, 2.953; trihydrate, 2.663. Lescaeur (*C. R.* 102, 1466) obtained only the penta-, tri-, and monohydrates.

Double salts with the alkali sulphates, of the form  $\text{CuSO}_4 \cdot \text{M}_2\text{SO}_4 \cdot 6\text{aq}$ , are obtained by crystallising mixtures of the constituents in the proper proportions v. Graham, *P. M.* 1835, 327, 417; Brunner, *P.* 15, 476; 32, 221; Pickering, *C. J.* 49, 1). Vohl (*A.* 94, 57) has described several triple salts of the form  $\text{CuSO}_4 \cdot \text{MSO}_4 \cdot 2\text{X}_2\text{SO}_4 \cdot 12\text{aq}$ , where  $\text{M} = \text{Fe}, \text{Zn}, \&c.$ , and  $\text{X} = \text{an alkali metal}$ ; and also quadruple salts  $\text{CuSO}_4 \cdot 2\text{MSO}_4 \cdot 3\text{X}_2\text{SO}_4 \cdot 18\text{aq}$ . Double salts of the form  $\text{CuSO}_4 \cdot \text{MSO}_4 \cdot 2\text{aq}$ ,  $x$  being 5 and 7, and  $\text{M}$  being  $\text{Co}, \text{Fe}, \text{Mg}, \text{Ni}, \text{or Zn}$ , are described (v. Rammelsberg, *P.* 91, 321; also Lefort, *A. Ch.* [3] 23, 95; von Hauer, *P.* 125, 638). Several basic salts of the form  $\text{CuSO}_4 \cdot x\text{CuO} \cdot \text{aq}$  are known:— $x=1$ , v. Roucher (*J. Ph.* [3] 37, 249);  $x=2$ , v. Reindel (*J. pr.* 100, 1; 102, 264), Persoz (*A. Ch.* [3] 25, 257), Shenstone (*C. J.* 47, 375);  $x=3$ , v. Smith (*J.* 25, 280), Pickering (*C. J.* 43, 336; 49, 1), Grimbert & Barré (*J. Ph.* [5] 21, 414), Kühn (*Ph. C.* 1847, 595), Kane (*A.* 19, 1);  $x=4$ , v. Smith (*L.*);  $x=7$ , v. Pickering (*L.*). For other basic sulphates v. Steinmann (*B.* 15, 1411), Brunner (*P.* 15, 476; 32, 221), Becquerel (*C. R.* 67, 1081), Casselmann (*Fr.* 4, 24).

• Didymium sulphates (v. Marignac, *A. Ch.* [3] 58, 148; Cleve, *Bl.* [2] 21, 246; 39, 151; Hermann, *J. pr.* 82, 385; Frerichs & Smith, *A.* 191, 348). The normal salt  $\text{Di}_2(\text{SO}_4)_3 \cdot 8\text{aq}$  crystallises in red, lustrous, monoclinic crystals from a solution of  $\text{Di}_2\text{O}_3$  or  $\text{Di}_2(\text{CO}_3)_3$  in excess of  $\text{H}_2\text{SO}_4$  aq; S.G. 2.878; S.H. 1948 (Nilson & Pettersson, *B.* 13, 1459). Heated to  $300^\circ$  loses all water of crystallisation, leaving  $\text{Di}_2(\text{SO}_4)_3$  as a red powder; S.G. 3.735; S.H. 1187 (*N.* & *P.*, *L.*); S. 43.1 at  $12^\circ$ , 11 at  $50^\circ$ , 2 at  $100^\circ$  (Marignac). For effect of heat at various temperatures v. Bailey (*C. J.* 51, 682). Hydrates with 8aq and aq crystallise from cold saturated solutions of  $\text{Di}_2(\text{SO}_4)_3$ ; Marignac (*L.*) also obtained a hydrate with 9aq. Double salts of the form  $\text{Di}_2(\text{SO}_4)_3 \cdot \text{M}_2\text{SO}_4 \cdot 8\text{aq}$ , where  $\text{M}$  is an alkali metal, are known. Basic salts are formed by heating the normal salt, also by adding a little  $\text{NH}_4\text{Aq}$  to solutions of the normal salt.

Gold sulphates. The normal *auro-auro* sulphate  $\text{AuSO}_4$  was obtained by Schottländer (*A.* 217, 312) by evaporating solution of

$\text{AuO.H.SO}_4$  (v. *supra*) nearly to dryness at  $250^\circ$ , and drying in a desiccator over lime. Lustrous, scarlet prisms, that rapidly absorb moisture from the air, with partial decomposition. A basic salt  $\text{AuO.H.SO}_4$  (auryl sulphate) was obtained (S. L.), as a yellow crystalline powder, by heating  $\text{AuO.NO}_3$  with conc.  $\text{H}_2\text{SO}_4$  at c.  $200^\circ$  ( $\text{AuO.NO}_3$  was formed by dissolving  $\text{AuO}_2\text{H}_2$  in  $\text{HNO}_3$  aq. S.G. 1.4, filtering through asbestos, and evaporating under reduced pressure over lime and soda). A double salt  $\text{AuK(SO}_4)_2$  was formed by dissolving  $\text{KHSO}_4$  in solution of  $\text{AuO.H.SO}_4$ , and evaporating at  $200^\circ$  (v. also Allen, C. N. 25, 85).

Indium sulphates (v. Winkler, J. pr. 94, 1; 95, 414; 98, 344; 102, 273; B. Meyer, A. 150, 429). The normal salt  $\text{In}_2(\text{SO}_4)_3$  is obtained by dissolving In or  $\text{InO}_2\text{H}_2$  in excess of  $\text{H}_2\text{SO}_4$  aq. evaporating to dryness, and heating till excess of acid is removed; a white, very hygroscopic powder; S.H. 129 (Nilson a. Pettersson, B. 13, 1459). S.G. 3.438 (N. a. P., C. R. 91, 232). By dissolving in water and evaporating, a hydrate with 9aq is obtained as a gummy solid. The solution of In or  $\text{InO}_2\text{H}_2$  in excess of  $\text{H}_2\text{SO}_4$  aq. yields a syrupy liquid on evaporation which probably contains an acid salt (?  $\text{In}_2(\text{SO}_4)_2.\text{H}_2\text{SO}_4$ ). By adding  $(\text{NH}_4)_2\text{SO}_4$  to solution of  $\text{In}_2(\text{SO}_4)_3$ , and evaporating, the double salt with the composition  $\text{In}_2(\text{SO}_4)_3.(\text{NH}_4)_2\text{SO}_4.24\text{aq}$  is obtained; this salt is an alum; it is sol. in  $\frac{1}{2}$  part water at  $16^\circ$ , and in  $\frac{1}{4}$  part water at  $30^\circ$ . On evaporating the mother-liquor, the salt  $\text{In}_2(\text{SO}_4)_3.(\text{NH}_4)_2\text{SO}_4.8\text{aq}$  is obtained (Rössler, J. pr. [2] 7, 13). Double salts with  $\text{K}_2\text{SO}_4$  and  $\text{Na}_2\text{SO}_4$  crystallising with 8aq, have also been obtained.

Iridium sulphates. By treating  $\text{IrS}_2$  with conc.  $\text{HNO}_3$  aq. Birnbaum (A. 136, 179) obtained an amorphous, brownish-yellow solid, easily sol. water, probably a sulphate of Ir. The double salt  $\text{Ir}_2(\text{SO}_4)_3.3\text{K}_2\text{SO}_4$  was obtained by Lecoq de Boisbaudran (C. R. 96, 1406, 1551) by fusing  $\text{KHSO}_4$  with Ir compounds, treating with water containing  $\text{KHSO}_4$ , dissolving the residue in hot water, and crystallising; green, translucent crystals, probably regular octahedra; almost insol. saturated  $\text{KHSO}_4$  aq.

Iron sulphates. I. Ferrous salts. The normal salt,  $\text{FeSO}_4$ , is obtained by heating powdered  $\text{FeSO}_4.7\text{aq}$  very carefully to  $300^\circ$  till it ceases to lose weight (the heating is best done in a stream of H); at a slightly higher temperature  $\text{SO}_2$  and O begin to be given off, and finally  $\text{Fe}_2\text{O}_3$  remains.  $\text{FeSO}_4$  is a white powder; S.G. 3.346 (Thorpe a. Watts, C. J. 37, 102). Several hydrates of  $\text{FeSO}_4$  are known, ordinary green vitriol being the most common and best examined of these; this heptahydrate,  $\text{FeSO}_4.7\text{aq}$ , is best prepared by adding iron filings to warm dilute  $\text{H}_2\text{SO}_4$  aq. until the acid is saturated and a little iron remains undissolved, boiling for a little, filtering into a vessel that has been rinsed with a very little conc.  $\text{H}_2\text{SO}_4$ , allowing to crystallise, washing the crystals two or three times with very small quantities of cold water, and then with alcohol till all acid is removed, drying at c.  $80^\circ$ , powdering the dry crystals, and strongly pressing between paper or linen. As thus prepared the salt does not readily oxidise in the air. If alcohol is added to the hot solution, filtered from undissolved

iron,  $\text{FeSO}_4.7\text{aq}$  is ppd. in minute crystals; if this pp. is washed with alcohol till acid is removed and then spread on filter paper, in dry air, till the alcohol has evaporated, the salt is obtained as a bluish white powder, which does not oxidise except in very moist air. Blue-green, monoclinic crystals; S.G. 1.8899 at  $4^\circ$  (Playfair a. Joule, C. J. 1, 138), 1.9854 at  $16^\circ$  (Pape, P. 120, 872). H.F. [ $\text{Fe}_2\text{S}_2\text{O}_7.7\text{H}_2\text{O}$ ] = 240,100 (Th. 3, 516). Heated to  $100^\circ$  gives off  $6\text{H}_2\text{O}$ , and at c.  $300^\circ$  leaves  $\text{FeSO}_4$  (v. *supra*). S.  $60.9$  at  $10^\circ$ ,  $70$  at  $15^\circ$ ,  $114.95$  at  $25^\circ$ ,  $227.27$  at  $46^\circ$ ,  $263.15$  at  $60^\circ$ ,  $270.27$  at  $84^\circ$ ,  $370.37$  at  $90^\circ$ ,  $333.33$  at  $100^\circ$ . Gerlach (D. P. J. 181, 129) gives the following data (v. also Schiff, D. P. J. 1858, 38):—

S.G. $\text{FeSO}_4$ aq.	Pctge. $\text{FeSO}_4.7\text{aq}$	Pctge. $\text{FeSO}_4$
1.0267	5	2.811
1.0537	10	5.784
1.0828	15	8.934
1.1124	20	12.164
1.1430	25	15.634
1.1738	30	19.622
1.2063	35	23.672
1.2391	40	27.995

Insol. glacial acetic acid and absolute alcohol.  $\text{FeSO}_4.7\text{aq}$  is fairly easily oxidised; exposure to air produces basic ferric sulphates.  $\text{FeSO}_4$  aq. absorbs NO, forming  $\text{FeSO}_4.x\text{NO}$  (x probably = 1 or  $\frac{1}{2}$ ; v. Gay, A. Ch. [6] 5, 145, and cf. Nitric oxide, vol. iii. p. 563). Other hydrates of ferrous sulphate are (1)  $\text{FeSO}_4.4\text{aq}$ , formed by crystallising  $\text{FeSO}_4$  aq. at  $80^\circ$  (Regnault, A. Ch. [3] 1, 201), also by exposing finely-powdered  $\text{FeSO}_4.7\text{aq}$  over  $\text{H}_2\text{SO}_4$  in an atmosphere of  $\text{CO}_2$  until it ceases to lose weight (Thorpe a. Watts, C. J. 37, 102); S.G. 2.227 (T. a. W.); (2)  $\text{FeSO}_4.3\text{aq}$ , by evaporating  $\text{FeSO}_4$  aq. made strongly acid by  $\text{H}_2\text{SO}_4$  (Kühn, S. 61, 235), also by dissolving  $\text{FeSO}_4.7\text{aq}$  in hot  $\text{HCl}$  aq. and crystallising (Kane, A. 19, 7); (3)  $\text{FeSO}_4.2\text{aq}$  by boiling the heptahydrate with successive quantities of alcohol; S.G. 2.773 (T. a. W., l.c.); (4)  $\text{FeSO}_4$  aq. by heating powdered  $\text{FeSO}_4.7\text{aq}$  to  $120^\circ$  in H; S.G. 2.994 (T. a. W.; v. also Mitscherlich, P. 18, 152). Several double salts of ferrous sulphate are known; they are generally prepared by crystallising a mixture of the constituent sulphates in the proper proportions. The salts  $\text{FeSO}_4.M.\text{SO}_4.6\text{aq}$ , where  $M = \text{NH}_4, \text{K}, \text{Na}, \text{or Tl}$ , form blue-green monoclinic crystals (v. Marignac, Ann. M. [5] 9, 19; Schiff, A. 108, 326; Tobler, A. 95, 193; Wilm, A. Ch. [4] 5, 56). For the salts  $\text{FeSO}_4.M.\text{SO}_4.14\text{aq}$ , where  $M = \text{Mg or Zn}$ , v. Schiff (l.c.), and Murmann (W. A. B. 27, 172). For various triple and quadruple salts containing  $\text{FeSO}_4$ , alkali sulphates, and sulphates of Mn, Mg, Zn, &c., v. Bette (A. 14, 278) and Vohl (A. 94, 57).

II. Ferric salts. The normal salt  $\text{Fe}_2(\text{SO}_4)_3$  is obtained by adding 1 part conc.  $\text{H}_2\text{SO}_4$  to 5 parts  $\text{FeSO}_4.7\text{aq}$  dissolved in water, warming, and adding  $\text{HNO}_3$  aq. little by little till oxidation is complete, evaporating to a syrup, and then heating very cautiously so long as acid fumes are given off; on cooling  $\text{Fe}_2(\text{SO}_4)_3$  remains as a white amorphous solid; S.G. 3.097 at  $18^\circ$  (Pettersson, Upsala, Nova acta, 1874). Fairly large quantities of  $\text{FeSO}_4.7\text{aq}$  should be used, as evaporation of a dilute solution containing  $\text{Fe}_2(\text{SO}_4)_3$  produces ppn. of basic sulphates. The hydrate  $\text{Fe}_2(\text{SO}_4)_3.9\text{aq}$  occurs native as

obtained rhombic leaflets of a hydrate with 10aq (*J.* 1874, 268).  $\text{Fe}_2(\text{SO}_4)_3$  is slowly sol. in water; the presence of a very small quantity of  $\text{FeSO}_4$  causes  $\text{Fe}_2(\text{SO}_4)_3$  to dissolve rapidly in water (Barreswil, *Ph.* *C.* 1845, 604).  $\text{Fe}_2(\text{SO}_4)_3$  is insol. in conc.  $\text{H}_2\text{SO}_4$ ; it is reduced to  $\text{FeSO}_4$  by most metals, more quickly if a little  $\text{H}_2\text{SO}_4$  is present.  $\text{Fe}_2(\text{SO}_4)_3$  forms several double salts. The compounds  $\text{Fe}_2(\text{SO}_4)_3 \cdot \text{M}_2\text{SO}_4 \cdot 24\text{aq}$ , where  $\text{M} = \text{NH}_4$  or  $\text{K}$ , are alums. Potash iron alum  $\text{Fe}_2(\text{SO}_4)_3 \cdot \text{K}_2\text{SO}_4 \cdot 24\text{aq}$  is prepared by dissolving 28 parts  $\text{FeSO}_4 \cdot 7\text{aq}$  in water, adding 5 parts conc.  $\text{H}_2\text{SO}_4$ , oxidising by  $\text{HNO}_3$  aq, adding 8.75 parts  $\text{K}_2\text{SO}_4$ , and crystallising; or by mixing 10 parts powdered  $\text{FeSO}_4 \cdot 7\text{aq}$  with 4 parts  $\text{KNO}_3$ , slowly adding 5 parts conc.  $\text{H}_2\text{SO}_4$ , warming so long as  $\text{NO}_2$  is given off, dissolving the residue in 4 times its weight of water at  $80^\circ$ , and allowing to stand at  $0^\circ$  for some time (Heintz, *A.* 44, 271). The salt slowly decomposes in the air; heated to  $80^\circ$  it gives  $\text{Fe}_2(\text{SO}_4)_3$ , basic ferric sulphate, and  $\text{H}_2\text{SO}_4$ ; a similar decomposition occurs when an aqueous solution of the salt is heated (Rose, *P.* 94, 459). Addition of  $\text{KOH}$  aq to a conc. solution of the salt till a slight permanent pp. is formed, followed by evaporation, produces a double salt of  $\text{K}_2\text{SO}_4$  with a basic ferric sulphate (v. Richter a. Scheerer, *P.* 87, 73). Ammonia iron alum is formed similarly to the  $\text{K}$  salt; loses  $23\text{H}_2\text{O}$  at  $150^\circ$  (v. Lupton, *C. J.* 28, 201). For double salts with  $\text{Al}_2(\text{SO}_4)_3$ ,  $\text{Cr}_2(\text{SO}_4)_3$ ,  $\text{Mn}_2(\text{SO}_4)_3$ , and  $\text{MnSO}_4$ , v. Etard (*Bl.* [2] 31, 200). Some double compounds of  $\text{Fe}_2(\text{SO}_4)_3$  with  $(\text{NH}_4)_2\text{SO}_4$ , and with  $\text{FeSO}_4$  and  $(\text{NH}_4)_2\text{SO}_4$ , are described by Lachaud a. Lepierre (*C. R.* 114, 915).

A great many basic salts have been described; generally prepared by the action of air on solutions of  $\text{FeSO}_4 \cdot 7\text{aq}$ , or by heating  $\text{Fe}_2(\text{SO}_4)_3$  aq in sealed tubes (v. Athanasesco, *C. R.* 103, 271). Pickering (*C. J.* 37, 807) gives very full references to all the memoirs on those basic salts, and comes to the conclusion that only one exists, viz.  $2\text{Fe}_2\text{O}_3 \cdot \text{SO}_3$ ; in a later paper (*C. J.* 43, 182) he gives reasons for writing the formula rather as  $6\text{Fe}_2\text{O}_3 \cdot 3\text{SO}_3 \cdot x\text{H}_2\text{O}$ , or  $\text{Fe}_2(\text{SO}_4)_3 \cdot 5\text{Fe}_2\text{O}_3 \cdot x\text{H}_2\text{O}$ .

Lanthanum sulphates. The normal salt  $\text{La}_2(\text{SO}_4)_3$  is obtained by dissolving  $\text{La}_2\text{O}_3$  in excess of  $\text{H}_2\text{SO}_4$  aq, evaporating, drying the crystals of  $\text{La}_2(\text{SO}_4)_3 \cdot 9\text{aq}$  that separate, and heating to dull redness; a white powder, S.G. 8.6 (Nilson a. Pettersson, *C. R.* 91, 232); S.H. 1182 (N. a. P., *B.* 13, 1459). Much more sol. cold than hot water; Mosander (*P.* 11, 406) gives S. 16.6 at  $2^\circ$ – $3^\circ$ , 2.35 at  $25^\circ$ , .87 at  $100^\circ$ . The hydrate with 9aq, formed by the slow evaporation of  $\text{La}_2\text{O}_3$  in excess of  $\text{H}_2\text{SO}_4$  aq, crystallises in large, lustrous, hexagonal prisms (Topsoe); S.G. 2.853 (N. a. P., *C. R.* 91, 232). A hydrate with 6aq was obtained by Frerichs a. Smith (*A.* 191, 331). Several double salts with the alkali sulphates have been obtained; the principal are  $\text{M}(\text{NH}_4)_2\text{SO}_4 \cdot 8\text{aq}$ ,  $\text{M} \cdot 8\text{K}_2\text{SO}_4$ , and  $\text{M} \cdot 4\text{K}_2\text{SO}_4$ , where  $\text{M} = \text{La}_2(\text{SO}_4)_3$  (v. Cleve, *Bl.* [2] 89, 151; 43, 56). A basic salt was obtained by F. a. S. (*L.c.* p. 860).

Lead sulphates. The normal salt  $\text{PbSO}_4$  occurs in various lead ores. It is obtained as a white, heavy powder, by heating  $\text{Pb}$  with conc.  $\text{H}_2\text{SO}_4$ , by the interaction of warm  $\text{H}_2\text{SO}_4$  aq

and  $\text{PbO}$ , or of  $\text{PbO}_2$  and  $\text{SO}_2$ , and by ppg. solutions of lead salts by dilute  $\text{H}_2\text{SO}_4$  aq or solution of a sulphate.  $\text{PbSO}_4$  is prepared in small rhombic crystals by melting  $\text{PbCl}_2$  with  $\text{K}_2\text{SO}_4$ , and washing with water. S.G. 6.2 (Schröder, *P. Ergdn.* Bd. 6, 622); 5.96 at  $17^\circ$  (Pettersson, *Upsala, Nova Acta*, 1874). H.F. [ $\text{Pb}, \text{S}, \text{O}$ ] = 216,200 (*Th.* 8, 516). Nearly insol. water; Rodwell (*C. N.* 11, 50) says that 81,062 parts water at  $15^\circ$  dissolves 1 part  $\text{PbSO}_4$ . Struve (*Fr.* 9, 84) gives S. in conc.  $\text{H}_2\text{SO}_4$  as .13, and S. in Nordhausen acid as 4.19 (v. also Kolb, *D. P. J.* 209, 268). For solubility in dilute  $\text{HCl}$  aq and  $\text{HNO}_3$  aq v. Rodwell (*C. J.* 15, 59); for S. in various salt solutions v. Löwe (*J.* 1859, 63); Staedel (*J.* 1863, 245); Storer (*C. N.* 21, 17); Dibbits (*Fr.* 1874, 137). Heated to redness,  $\text{PbSO}_4$  melts without decomposition, but at a white heat it gives  $\text{PbO}$ ,  $\text{SO}_2$ , and  $\text{O}$  (Boussingault, *C. R.* 64, 1159). Heated in a stream of  $\text{H}_2$ , it is reduced to  $\text{Pb}$  with evolution of  $\text{SO}_2$ ,  $\text{H}_2\text{S}$ , and steam; heated with charcoal,  $\text{PbO}$ ,  $\text{PbS}$ , or  $\text{Pb}$  is formed according to the proportions of the reacting substances. Reduced by  $\text{Fe}$  or  $\text{Zn}$  in contact with water. Rubbed with  $\text{K}_2\text{CrO}_4$ , produces  $\text{PbCrO}_4$ ; with  $\text{KI}$  aq yields  $\text{PbI}_2$ , and with  $\text{NaCl}$  is partly decomposed to  $\text{PbCl}_2$  (v. Matthey, *Ar. Ph.* [3] 13, 233). For reaction when heated in  $\text{NH}_3$  v. Rodwell (*C. N.* 15, 137). A double salt  $\text{PbSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4$  is formed by adding excess of  $\text{H}_2\text{SO}_4$  aq to  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$  aq, neutralising excess of acid by  $\text{NH}_3$  aq, boiling, and allowing to cool. An acid salt  $\text{PbSO}_4 \cdot \text{H}_2\text{SO}_4$  aq was obtained by Schultze (*P.* 133, 137) by dissolving  $\text{PbSO}_4$  in conc.  $\text{H}_2\text{SO}_4$  and setting aside. A basic salt  $\text{PbSO}_4 \cdot \text{PbO}$  is formed by digesting  $\text{PbSO}_4$  with  $\text{NH}_3$  aq (Kühn, *Ar. Ph.* [2] 50, 281).

Lithium sulphates. The normal salt  $\text{Li}_2\text{SO}_4$  is obtained by dissolving  $\text{Li}_2\text{CO}_3$  in  $\text{H}_2\text{SO}_4$  aq, evaporating, drying the crystals of  $\text{Li}_2\text{SO}_4$  aq that separate, and heating them to c.  $135^\circ$ . S.G. 2.21 at  $15^\circ$  (Brauner, *P. M.* [5] 11, 67). Melts at  $818^\circ$  (Carnelley, *C. J.* 33, 280). S. 35.34 at  $0^\circ$ , 34.36 at  $20^\circ$ , 32.8 at  $45^\circ$ , 30.3 at  $65^\circ$ , 29.24 at  $100^\circ$  (Kremers, *A.* 99, 47). Easily sol. alcohol; insol.  $\text{SO}_2$  (Weber). H.F. [ $\text{Li}, \text{S}, \text{O}$ ] = 333,200 (*Th.* 3, 516). Heated in  $\text{HCl}$  gas below redness gives  $\text{LiCl}$  (Hensgen, *B.* 8, 125). The monohydrate  $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  aq crystallises in monoclinic forms (Rammelsberg, *P.* 123, 311). S.G. 2.052 at  $21^\circ$  (Pettersson, *Upsala, Nova Acta*, 1874). Effloresces a little in air, gives up water at a little above  $130^\circ$ . An acid salt  $\text{LiHSO}_4$  is obtained by dissolving  $\text{Li}_2\text{SO}_4$  in  $\text{H}_2\text{SO}_4$  aq S.G. 1.6 to 1.7 (Schultz, *P.* 130, 149); prismatic crystals, melting at c.  $120^\circ$  (Lescœur, *Bl.* [2] 24, 516). Double salts with  $\text{K}_2\text{SO}_4$  are obtained by evaporating mixed solutions of the constituent salts (v. Rammelsberg, *A.* 123, 311; Schabus, *J.* 1854, 623). For double salts with  $\text{Rb}_2\text{SO}_4$  and  $\text{Na}_2\text{SO}_4$ , v. Wyruboff (*Bull. soc. mineral. de France*, 1882, part 2). Wernicke (*P.* 159, 576) describes a salt  $3\text{Li}_2\text{SO}_4 \cdot \text{Cr}_2(\text{SO}_4)_3$ , formed in green needles, by adding  $\text{Cr}_2\text{O}_3$  to molten  $\text{LiHSO}_4$ .  $\text{Li}_2\text{SO}_4$  does not form alums, nor does it combine with the magnesium sulphates (Rammelsberg, *l.c.*; Scheibler, *J. pr.* 67, 485).

Magnesium sulphates. The normal salt  $\text{MgSO}_4$  is obtained by dissolving  $\text{MgO}$  or  $\text{MgCO}_3$  in  $\text{H}_2\text{SO}_4$  aq (or by heating dolomite till  $\text{CO}_2$  is

# SULPHATES.
